Of course, I am far from saying that the construction of the one I am about to describe has not been elaborated or, if the reader likes to consider it so, even improved. A glance at those in an artists' colourman's shop will show that. At the same time, it is open to question if these alterations are always improvements. Extreme lightness may be got at the sacrifice of strength, and the other modifications may rather be regarded as luxuries than as actual necessities. However, I have not to do with the nicely finished arrangements of the artists' colourman so much as with a good, practical easel which can be made in the simplest manner with materials which can be found anywhere. The constructive work, also, is so trifling and of such an easy character that even the novice at wood-working can manage it, and in the event of his not being inclined to do it himself, the most unskilled and thickest-headed country carpenter cannot have the slightest difficulty in grasping the main features and carrying them out in a satisfactory manner. From this it will be gathered that the cost is small. As some guide to those who want to get one of these easels made, I may say that the one from which this description is taken cost me 1s. 6d. complete from the village joiner who made it for me.

By referring to the illustration (Fig. 1), it will be seen that the easel is formed of three legs, the back one being merely a support for the other two, on which the canvas rests. Now what may be called the actual making is of the very slightest, as, beyond smoothing and cleaning up the three long pieces, it consists almost entirely in the formation of the block at the top, to which they are attached. This block is shown on an enlarged scale in Fig. 2, and may as well be of some comparatively hard wood, such as beech—anything, in fact, that is harder than common pine, which, however, will do very well for the other parts, and may be used even for this one.

The dimensions of the various parts can best be regulated by individual requirements, so that I cannot say much about them, and beyond determining the substance of the three long pieces, we have little to do with them at present. I may, however, say that in the easel referred to the parts are all of 1 in. stuff. The only reason for making any remark about this now is that the size of the opening of the block may be made to correspond with the width of the top of the back leg, which is fitted within it. If it corresponds in thickness, so much the better for appearance, but not for any other reason. Let us suppose the width to be 1 in.

Hinge the end of the back leg by means of a piece of wire—a French nail will do very well—driven through as shown by dotted line in Fig. 3.

The front pieces now have to be fastened to the block, and this may be done easily by means of a screw-nail through each. The plain parts of the screw-nails will allow of the legs moving sufficiently easily on them; and to allow of the legs opening outwards, the holes should be placed near their ends, which should be rounded as in Fig. 4.

It will now be seen that the front legs can

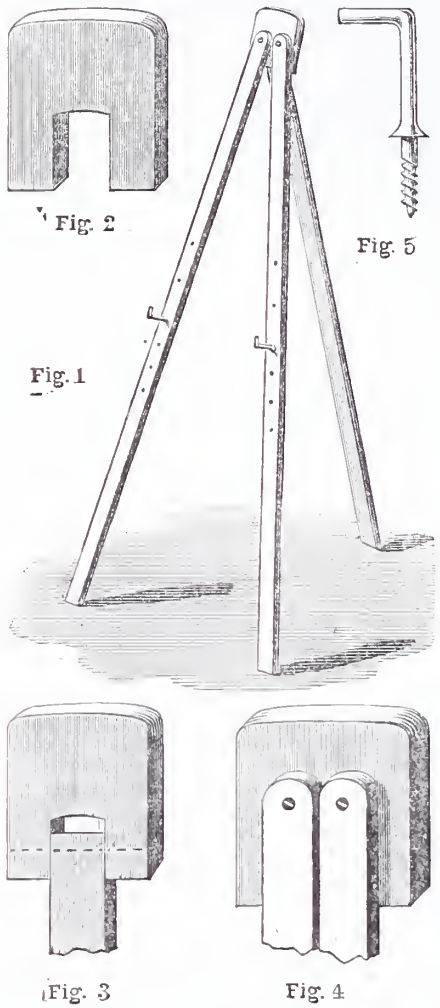

Fig. 1.—Easel. Fig. 2.—Block for Top. Fig. 3.—Back Support fastened to Top. Fig. 4.—Front Supports fastened to Block. Fig. 5.—Screw-Hook.

be spread open sideways, and that the back one will support them at any desired slope, while, when the easel is folded, they lie close together, and form as compact a bundle as possible.

To complete the easel, it is only necessary to bore holes at intervals through the two front pieces, so that pegs may be inserted in them for the canvas to rest on. For the pegs themselves almost any short pieces of stick will do. My own are nothing but bits of twig cut off with a piece of a projecting branch left on at the outer end, thus forming a kind of rough hook within which the bottom of the canvas lies, so that it is prevented from accidentally slipping off.

The ends of the legs may be left as they are, but it will be better to fix a piece of stout wire or thin iron rod into each to prevent them slipping, and to allow of their being firmly fixed. If wire is not handy, they may be simply sharpened to a point, so that when sketching in fields or on soft ground they can be driven into the earth. Of course, the points will want sharpening occasionally, as they will, under ordinary circumstances, soon get worn away. As everyone who has painted in the open air knows, it is necessary often to fasten both canvas and easel so that they may not be blown over; but novices may not quite see how it can be managed, as it may be, very easily. So far as the easel itself is concerned, there is no difficulty when the ground is sufficiently soft to allow of its points being driven in. It is not always, however, that this can be done, and then some other means must be adopted. The simplest is to fasten a piece of rope or sufficiently thick string by one end to the top block, and to the other end fasten a stone or anything else—such as a rod—that may be handy, and let it hang near the ground.

It is not, however, the easel itself which catches the wind as much as the canvas; and everyone knows how awkward it is for this, when the paint is wet, to be blown down—perhaps, in the effort to save it, right on to the palette. Various contrivances may be adopted to secure it to the easel, but it will be unnecessary to do more than suggest the simplest. One way, which will no doubt readily occur to the young artist, is to fasten a small nail or two into the top edge of the canvas stretcher. A piece of string tied there and to the easel will then make all secure.

Another and somewhat neater-looking way, but I do not think any more serviceable method, is to screw a hook into one or both of the front legs just above the top of the canvas. By slightly turning the hook, the picture may be fastened or released as occasion may require. The ordinary brass screw-hook (Fig. 5) does as well as anything for the purpose, and is easily obtainable.

A still cruder method, but one not always convenient, is to tie a piece of string over the front of the canvas and round the easel; enough has doubtless been said to show that any simple way which may be found satisfactory will do equally as well as the most complicated arrangement of clips.

Nothing has been said about the height of the easel, for naturally this must depend on circumstances. For instance, much will depend on the size of the paintings and whether the artist intends to sit or stand to his work. If he habitually sits, a much shorter one will do than for a standing position, but I may name what I consider a fair average size—viz., about 5 ft.; while for a sitter, probably 4 ft. will be found sufficient in the majority of cases. It will easily be understood that it is not advisable to have the easel too long, not so much on account of inconvenience while painting as of its being cumbersome for transport; nor, on the other hand, too short and, consequently, awkward to paint at.

For small and, consequently, light paintings, even slighter substance than 1 in. square will do very well; and those who want to make the easel still more portable than as described, can do so by cutting each leg in half and bringing the parts together by means of a screw, or other suitable tie. A piece of stout wire or French nail passed through holes will prevent the legs collapsing, and render them sufficiently rigid when the easel is in use.

Of course, it must not be understood that a more highly finished easel might not have

been described, but to have done so would have been to increase the difficulty and cost of making without in any material degree increasing what I may call its workable capacity. The maker might, for instance, have been advised to make it of mahogany, and carefully French-polish it; but *cui bono?*

I have spent many pleasant hours in company with such an easel and its accompaniments of paints, brushes, palette, canvas, etc., out of doors when sketching, and have not disdained to use it in the house. I think any readers of Work will not regret adopting the pattern if they are on the look-out for a cheap, serviceable, and handy easel, whether for in- or out-door use.

## THE WINTER CARE OF CYCLES.

BY "CYCLOPS."

At this time of the year cyclists are thinking of stowing away their machines, and it may interest many readers of Work to know that a cycle, when stored for the winter, may be doing itself as much harm, and wearing itself away almost as much, as when in active service in the rider's use. This may seem, on the face of it, ridiculous, but a closer examination of the question will show that there is more truth in the seemingly sweeping assertion just made than is at first apparent.

I say "*may* be wearing itself away" advisedly, because there are many experienced cyclists who take care to put their machines away in good condition, and thus prevent this wear.

It must not be supposed that I am in favour of thus banishing for the winter a friend who has stood us in good stead during the summer. I myself am of opinion that almost as much pleasure can be had out of the constant use of the bicycle during the winter as during the summer; and any cyclist who has sallied forth on his machine on a clear frosty day, with a good hard macadamised road under his wheels, will testify to the exhilarating effects of such exercise—an enjoyment not to be compared with that of going forth on a hot day, with the rider's temperature almost at boiling point.

There is a distinct difference between the two feelings, and I am inclined to give the preference to the winter ride. But to return to our subject: There are no doubt many riders of cycles whose interest in their machines ceases with the advent of winter, and who take up some other hobby or pastime, and leave cycles and cycling to take care of themselves until summer comes round again. To these cyclists I would say: Take care, in putting away your machines, to make them thoroughly comfortable, as a coachman would his horses after a hard day's work.

It is often the case that a cyclist, going to his machine to get it into condition for use again, is surprised to find that it is looking very bad indeed. The enamel is, perhaps, cracked in many places; there are marked signs of the plating stripping; the spokes are rusty at the points where they enter the hubs and rims; the wheels, on being turned round, are found to be very stiff, and the pedals refuse to revolve when tried. All this may be avoided by carefully observing the following directions:

On deciding to put the machine away for the season, the first thing is to thoroughly clean it in every part. First remove all the dust and dirt with a cloth and stiff brush, then thoroughly clean all the bright parts as follows: Procure some very fine flour of emery, and mix into a thick paste with common paraffin oil; with a soft cloth and a small quantity of the paste thus formed rub all the bright parts carefully over, and dry with a clean rag; then polish with a soft duster and a little dry whiting, and finally, rub all over with a soft leather. This will take all the moisture out of the plating which may have got into it by exposure to rain, etc., and help to keep it from rusting and stripping off.

The enamelled parts next require our attention. They should be rubbed all over with a cloth dipped in benzoline, and afterwards carefully polished.

The machine, unless very much used and worn, will now have the appearance, almost, of a new one, and the worker will be surprised at the effect his labours have had on his old friend.

Before proceeding further, the bearings should be thoroughly run out with paraffin oil—or, better still, this could be done before the final polishing process.

The running out of the bearings may be effected as follows:—Support the wheel so that it is free to revolve, and underneath each side of it set a can to catch the paraffin which will drop out from each side of the bearing; then open the oil-cup, fill with paraffin, and revolve the wheel.

This should be continued until the paraffin, which at first runs out thick and black, has assumed its proper density, and runs through the bearings perfectly clear. This should be done with all the wheels, bearings, and pedals, and when they are all quite clear they should be carefully oiled with best machine oil.

Here let me caution the reader against the use of common oils, which only eat into the bearings, and eventually prevent that free movement they are intended to assist. Good oil may be procured from any sewing-machine shop, and, for the trifle of extra cost, it is far and away superior.

The next consideration is the chain. This should be taken off the machine by unscrewing the movable link, and soaked in paraffin oil until all dirt and grit are thoroughly removed. It should then be dried and well black-leaded, or rubbed with one of the many chain lubricants advertised in cycling journals, and afterwards fitted on the machine again.

We must now procure some vaseline, or, as it is known in the trade, petroleum jelly. This may be got by the half-pound of any chemist, and should any be left over, it will come in useful for putting on the hands in frosty weather, to prevent them getting chapped.

But this by the way. We must now thoroughly grease the whole of the machine over with vaseline, even including the saddle, as it will keep it from becoming hard and cracking.

Our machine is now ready to put away. The vaseline will keep the plated and enamelled parts from cracking, and the new oil in the clean bearings will prevent them clogging, so that when summer comes, all we have to do is to wipe the grease from our "iron horse," oil up, and set off for a run, without all the trouble and bother of first overhauling it. "Safe bind, safe find," is advice which holds good for cycles as well as other things, as will be found by all who follow the instructions given above. If the cycle is put away clean, it will be found clean when the time comes to use it again.

## TRAMMELS: THEIR USES, AND HOW TO MAKE THEM.

BY J. H.

Their Purpose—Description of Common Form—Pattern Work—Fitting up—Wooden Trammel—Ditto—Fine Adjustment—Drawing Trammel.

*Their Purpose.*—Trammels, or beam compasses, are used for striking circles and radii larger than can be embraced by dividers and ordinary compasses. They are used by fitters, pattern-makers, boiler-makers, and draughtsmen, and are more or less slightly modified according to their special uses.

Fig. 1 shows the common form used by fitters, pattern-makers, and boiler-makers. The only essential difference that need be made in these trammels is that when used on wood the points are ground off at a more acute angle than when used for metal.

*Description of Common Form.*—In Fig. 1, A is the body of the trammel, made of brass, sliding along the beam or bar, B, and pinched in any position with the screw, C. To avoid bruising the beam, there is a thin washer, D, interposed, with shouldered ends, to prevent it from slipping out endwise when the trammel head is being slid along. The pin E is formed of a bit of steel, either screwed into the boss on the body or driven into a drilled hole.

*Pattern Work.*—To make such a trammel, a pattern like Fig. 2 is necessary, where A is the pattern itself, and B, B, prints for carrying the core for taking out the holes. Leave extra metal—say $\frac{1}{16}$ in. in diameter—upon the bosses for turning, and a very little—say $\frac{1}{64}$ in.—on the finished sizes of the hole and the outside of the body for filing. Centre the bosses very truly to scribed centre lines, and see that the prints are cut quite central also. Attention to these minute details saves a deal of after trouble in filing up.

Fig. 3 is the core-box for taking out the interior of the body. It is a perfectly plain rectangular box, put together as shown. Be precise as to thickness, for if thicker or thinner than its prints there will be unequal thicknesses of metal in top and bottom sides.

On receipt of the castings, it does not much matter whether the turning or filing is done first. But I should proceed thus:—

*Fitting up.*—Plane up a short strip of hard wood, 6 in. or 8 in. in length, very accurately to the section of the trammel rod intended to be used. Have its faces quite parallel, and its edges at right angles. This, being smeared with red lead, is the gauge to which the holes in the trammel bodies will be filed out until they will just slide over it freely—neither head fitting tighter or slacker than the other. This will give some little trouble; and it will be as well to make another gauge strip just a shade smaller than the actual templet, and fit the heads roughly over that first.

To save the trouble of filing over the entire flat surface, those who make their own trammels often core them out concave, as shown in Fig. 4. Then, only about $\frac{1}{8}$ in. or $\frac{1}{4}$ in. at each end has to be actually filed instead of the entire surface. The outside of the casting is made convex, to retain a sufficiency of metal. Then the core-box is made like Fig. 5, the box sides taking the place of the open top and bottom of Fig. 3, and the concave portions are cut in the sides.

Having the inner faces true, slide both heads upon the gauge piece, and mark the centres of all the bosses with scriber block central with the strip, and squared over at

right angles with it. The holes in the bosses can then be drilled to these centres, and the bosses turned concentric with them. Each of these operations can be performed in one of two methods. The holes can be drilled by hand, holding the heads in the vice. But as they are liable to become out of perpendicular, the better plan is to drill them in the lathe, pinching the head on an angle-plate the while, and holding the drill in the slide-rest. Or the head may be clamped on the slide-rest, and the drill run in a drill-chuck. The bosses also may be turned while the head is held in an angle-plate; or the head may be clamped between dogs; or it may be held between centres with a small carrier at one end, and pivoted on the poppet centre at the other. In either case the boss nearest the poppet will have to be turned first, and then the head reversed to bring the other boss next the poppet for turning.

The flat faces, A, A, of the heads (Fig. 1) will be also skimmed over in the lathe. A quick speed will be used, and either hand or slide-rest tools will be employed for turning the bosses and facing the ends, and a file and emery-cloth will be used for polishing. After the turning is finished, the outside faces of the heads will be filed and polished.

It gives less trouble to cast a bit of brass for the screw than to turn it down out of steel or iron. It will be turned and milled, and then screwed.

The washer, D, is made from a pattern, or filed out of a bit of solid brass. Another form of washer answering equally well is shown in Fig. 6, where the ends, instead of being turned upwards, are spread at the sides.

The pin, E, is a bit of steel, which should be turned taper for good appearance, and driven into the body.

*Wooden Trammel Head.*—A cheap wooden trammel head is shown in Fig. 7. It is turned in hard wood, box being preferable, and bonded with small brass ferrules, A, at each end. The screw, B, is made of brass or steel, and its nut, C, consists simply of a square bit of brass or steel sunk into the trammel head within the slot cut through for the trammel rod. This plate will be about $\frac{1}{8}$ in. thick, to take three or four threads, and will wear an indefinite time. The washer, D, is of the form shown in Fig. 6. Such a trammel is very easily made, and yet for wood-work answers as well, or nearly as well, as a more elaborate one of metal.

Fig. 9, there is no pressure on the washer; but when the pin is turned round to bring the opposite or full portion lowermost, it presses upon the washer, D, and tightens the head.

The rounding of the bottom edge of the rod, F, is thought by some to be a slight advantage, as tending to increase the stability of the head upon the rod, giving a more wedge-like grip than a flat face would afford.

*Fine Adjustment.*—The pinching of the top screw of the trammel head does not alone furnish that precision of adjustment which is desirable for the most accurate kinds of work, such as the pitching out of centres of wheels, the striking of pitch circles, and other lines and centres where

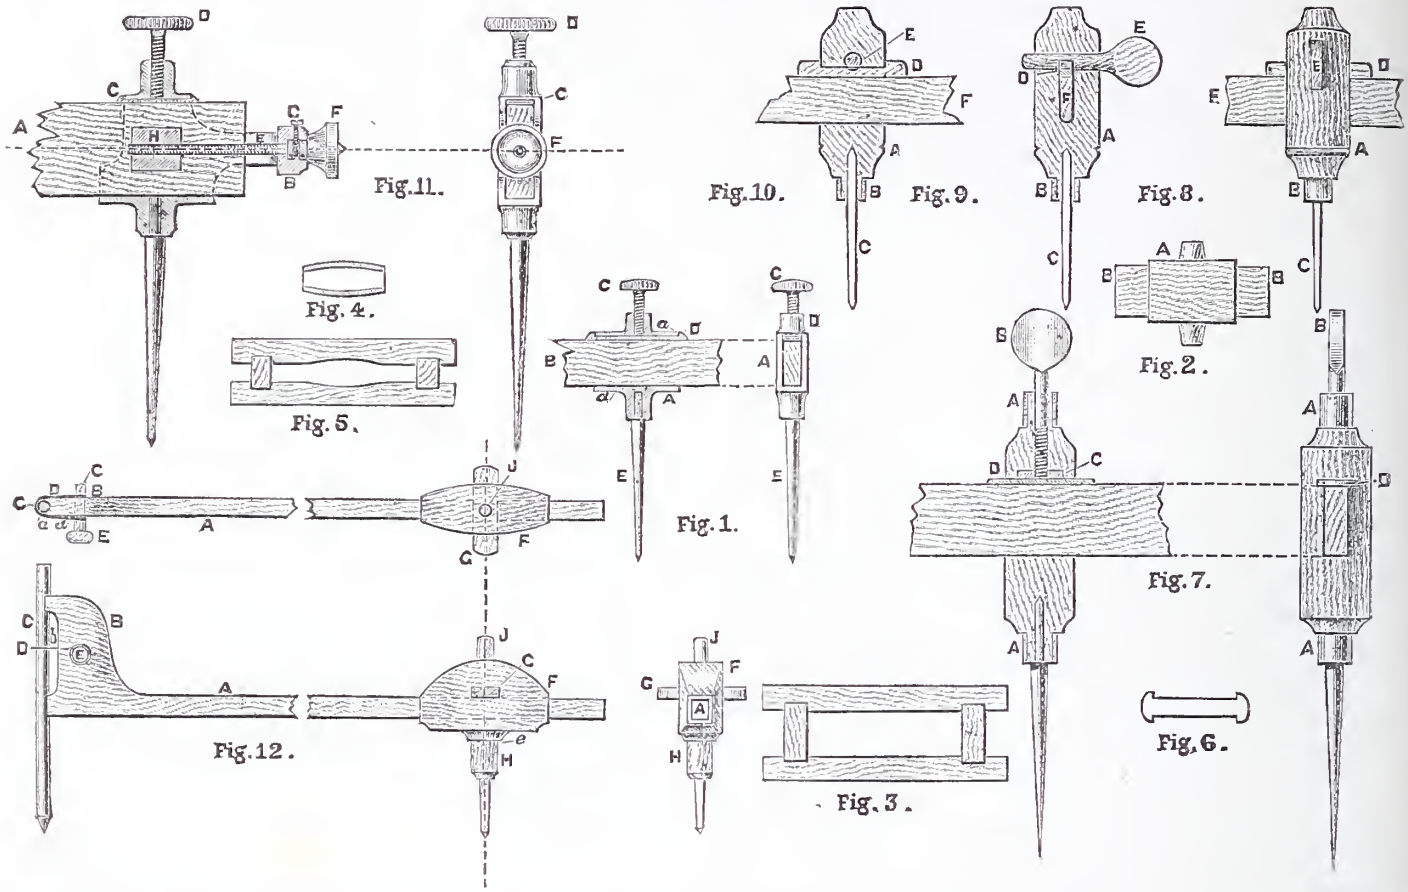

Fig. 1.—Brass Trammel Head. Fig. 2.—Pattern for same. Fig. 3.—Core-Box. Fig. 4.—Section of Concave and Convex Head. Fig. 5.—Core-Box for same. Fig. 6.—Form of Washer, alternative with that at D in Fig. 1. Fig. 7.—Wooden Trammel Head with Screw. Fig. 8.—Wooden Trammel Head with Cam. Fig. 9.—Ditto: Transverse Section. Fig. 10.—Ditto: Longitudinal Section. Fig. 11.—Brass Trammel Head with Fine Adjustment. Fig. 12.—Draughtsman's Pencil Trammels.

*Wooden Trammel.*—Figs. 8, 9, 10 give three views of a trammel head made in hard wood. It is very easily made, very simple in action, involves no metal work except the fitting on of the brass ferrule, and requires no screw cutting. Yet for wood-workers it is quite as serviceable as the trammels made entirely in metal.

Fig. 8 shows the trammel in outside elevation, and Figs. 9 and 10 in transverse and longitudinal sections respectively.

In these figures, A is the body of the trammel, turned of hard wood, and bonded with a small ferrule, B, to prevent the wood from becoming split on the driving in of the leg, C. Through the head passes the washer-piece, D, and the tightening-pin, or cam, E. The cam-like form is given to the pin, E, by simply cutting out a narrow portion at the centre (see Fig. 9) eccentrically. When, therefore, the pin is in the position shown in

adjustments of $\frac{1}{50}$ in. or $\frac{1}{100}$ in. are required. A fine adjustment, like the screw adjusted leg of a spring divider or of wing compasses, is then desirable. There are two or three ways of effecting this. I think the method shown in Fig. 11 is as good as any that I have seen, and I therefore illustrate it.

Of the two trammels used, only one is like that shown in Fig. 11, and it always remains near the end of the rod, A. The other is made without the extension, E, and slides anywhere on the rod. The narrowing of the upper part of the head where the washer, C, and screw, D, come is simply a fanciful form that one often sees, and is no essential part of the design; so that as regards the shape of the head in Fig. 11, it is simply a common trammel head, extended at the end, B, to form a boss through which passes the fine adjusting screw, E.

The mechanism of the screw, E, is seen in section in the figure. There is a turned and grooved portion next the milled head, F, which fits into a hole bored in the boss, B, of circular form. The purpose of this groove is to prevent the endlong movement of the screw, E, for the small pin, G, being tapped into the boss, and fitting into the groove, prevents any endlong movements, while allowing it to be turned freely by the fingers.

The screw is tapped into the gun-metal nut, H, which is a cubical block of brass let right through the trammel rod near the end, and drilled and tapped throughout longitudinally to receive the screw, E. Consequently, when the trammel head is set approximately, with the pinching screw, O, slackened, the turning of the milled head, F, of the fine adjusting screw, E, causes the screw to travel endlong in the nut, H, and so carries the trammel head along with it. When the correct adjustment is made, then the pinching screw is tightened.

*Drawing Trammel.*—A drawing trammel, useful to both draughtsmen and pattern-makers, is shown in Fig. 12. It is made of mahogany. The length of the staff, A, may be anything—say, from 2 ft. to 3 ft. long—2 ft. 6 in. being a useful average for ordinary drawings. Make it as follows :—

Plane up a piece of straight-grained mahogany to ½ in. thick, and of the full width of the head, B, at one end, which will then be cut out of the solid ; or plane a strip of mahogany to ½ in. square, and glue and screw the piece for the head upon one edge of it. The head is hollowed at *a* to receive the pencil, C, and is recessed at *b*, so that the pencil only bears at two points, and the tightening of the string, D, around it tightens it very firmly. The tightening is effected with the tapered button, E, which passes through a hole in the head. The string, D, is passed through a hole bored at C, and is turned once or twice round the pin at *d*. When, therefore, the button is turned in the proper direction, it tightens the string around the pencil, and a slight thrusting forward of the tapered pin, E, at the same time into its hole tightens it so that it will not slacken back of its own accord. The pencil is released as easily by the turning back of the button in the opposite direction.

The sliding head, F, is cut in a solid piece of mahogany. The hole is cut through first—not a difficult matter with centre-bit and chisel—and then the outer portions are shaped. The head is made deep in the middle, so that the pressure of the wedge, G—which is, however, only tightened with the fingers, not with the hammer—shall not be likely to split it off.

There are two turned portions fitted to the head into holes bored with a small centre-bit. One is the boss, H, into which the steel point is driven ; the other is the pin, J, upon which the finger is placed to steady the trammel when in use. The boss, H, terminates at *e*, the hollow which comes to meet it being cut out of the solid head. The wedge, G, bears directly upon the rod, and being broad, and only gentle pressure being exerted, it does not bruise it.

Of course, the details of such a tool as this are very much a matter of taste ; so, too, the dimensions can be varied. I simply copy from trammels of my own, and have seen a good many similarly made.

Provision is often made in brass trammels for the use of a pencil, by casting a boss upon the side of one head, and drilling a hole through it to receive the pencil, which may either be tightened with a screw or be a tight sliding fit only. This I need not illustrate.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

The Study: Dealing with an Objectionable Window—Mullions—Glazing without the Glazier—Panelling of Window—Glazing Door on Novel Plan.

*The Study: Dealing with an Objectionable Window.*—The only window to my study (as I found it) was a mean affair. It had a wooden frame divided into three lights by clumsy square wooden "uprights"—for of the name of "mullions" they were in no way deserving. Its glazing was of small square panes, set in broad lead-work, which by no means admitted a proper proportion of light ; in the middle compartment was also the further obstruction of a clumsy iron casement. This window was as inefficient for lighting purposes as it was unsightly ; and as its size was full small for the room, something had to be done with regard to it. To have made a larger opening would have been too serious an undertaking for me, so I had to do the best I could with the existing space.

As the room had a door to the open garden, I concluded that I should have abundant ventilation without the casement, which would make one difficulty the less. Accordingly I cleared out the leaded lights and the casement with them. The wooden "uprights" I sawed out, and in their stead inserted a single mullion. How this was constructed (and since it other mullions) must be more particularly described, as a useful wrinkle may thus be imparted.

*Mullions.*—Fig. 12 gives a section of the special mullion in question. Its body, A, is a piece of squared oak (the top, in fact, of one of the head-posts of an old-fashioned bedstead, other parts of which came in handy in other parts of my house). This I dowelled into the frame at top and bottom. On its four faces are screwed four strips of deal ; B is the outside strip, and this is so much longer than the mullion as to admit of its being screwed to the outside of the frame at top and bottom ; this, with the dowels, renders the mullion as firm as if it had been mortised in. The other three strips are of the same length as the body.

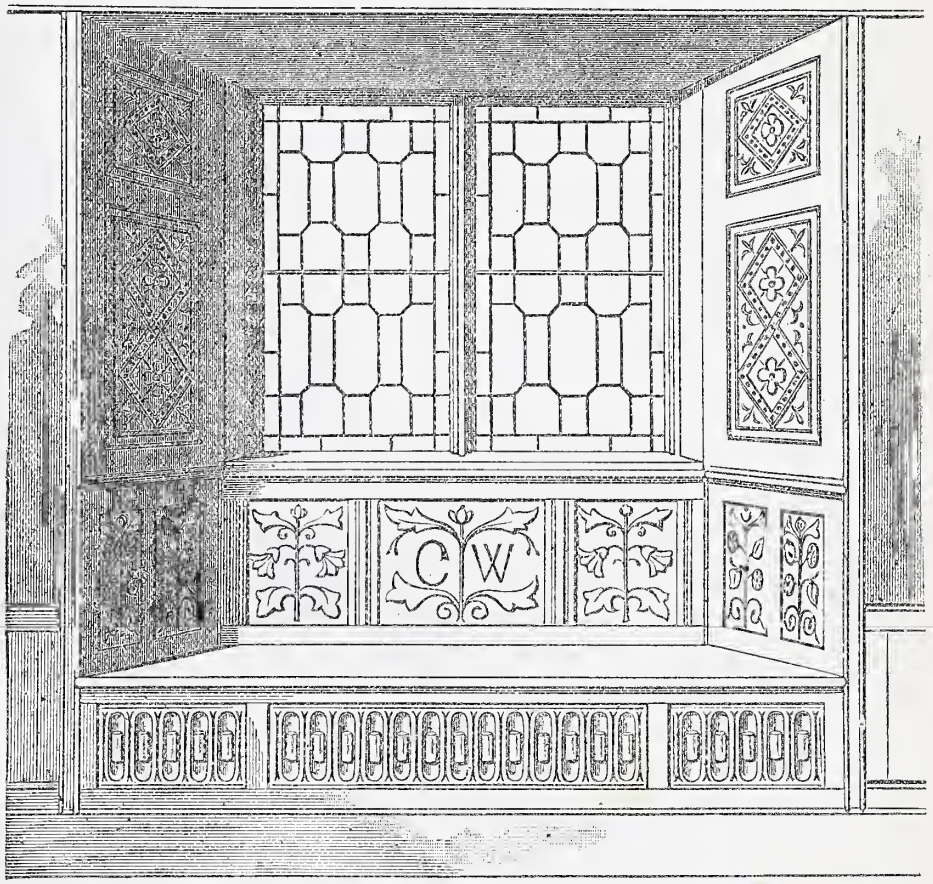

Fig. 11.—Study Window as improved.

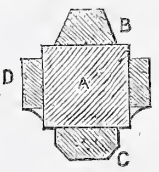

Fig. 12.—Section of Mullion of Window.

The strip C is screwed to the inner face ; the two strips, D, D, to the sides so as to form rebates to hold the leaded lights. To finish my mullion and to prevent any air from drawing through it, I laid putty up the angle at back of D, smoothing it down with a gouge, and thus making a round hollow moulding. The result was a firm, strong, boldly moulded mullion, fully equal for its purpose to one worked from the solid.

*Glazing without the Glazier.*—It will be seen from Fig. 11 that the reconstructed window was again fitted with leaded lights ; but these are both more decorative and less obstructive than the old ones. They are put together with thin string lead, which keeps out very little light. I might, of course, at less cost, have fitted each light

with a single sheet of glass, but this would not have suited the style of the room; besides which, as a general matter of taste, I consider moderately small panes to be far better in effect. Large panes have a cold and comfortless look, as they do not (in appearance) sufficiently cut off the room from the outside world.

The actual leading of the glass together was not done by myself, nor did I call in the glazier to help me. I found that the best and most economical way was to draw out on paper a full-sized cartoon of one of the lights, marking, of course, all the lead lines, and to send this to a wholesale Birmingham glass warehouse, from which the lights all already for fixing, with the necessary saddle-bars and ties, were promptly forwarded to me. These lights, 35 by 19 in., cost about 8s. or 9s. each. I fixed them in place myself, which was a very simple matter.

*Panelling of Window.*—The window had clumsy shutters of painted board. I removed them, and substituted some of my old oak panelling, as shown in Fig. 11. The carving upon it is my own, and its style is in keeping with some of the old carving round the fireplace and elsewhere. Below is a window-seat. This I also panelled round, the wood used being the front and ends of a small oak chest of, say, Cromwell's time, which I picked up at a sale for 2s. 6d. The initials C. W. on the central panel were there originally; the other ornamentation is incised work like that above the fireplace, and of my own doing. The pieces of gouge work below the seat are part of the wreckage of an old bedstead. The edge of this oak-work, on the side towards the room, was finished, as shown in the illustration, by an ebonised moulding.

*Glazing Door on Novel Plan.*—I have mentioned that this room had a door leading to the open air. As my only window was so small, I proposed to make this a passage for a little additional light. Had it been a panelled door I should simply have taken out the upper panels and filled their places with British plate glass; but it was not panelled, it was a plain ledger door, yet a strong well-fitting door of its kind, and gave me no excuse for going to the extravagance of a new one.

Now I had made a collection of things of a kind which, perhaps, no one else, of all the thousands who read WORK, has ever thought worth the collecting—namely, the feet of broken wine-glasses. But the reader must by this time have seen that I am an enthusiastic utiliser of odds and ends. I hold that by the judicious employment of such "unconsidered trifles," wonders can be worked at little cost; and that there are very few things which cannot be made of use if you only know how to use them; indeed, great part of the object of these articles is to indicate how odds and ends may be utilised to good purpose.

My small discs of glass—my wine-glass bottoms—I had thought might come in useful for ornamental (plain pattern) lead glazing; I now, instead, arranged them for my door in such a geometrical design as would best admit light without seriously interfering with strength; I then pierced my round holes through the wood, and puttied them in.

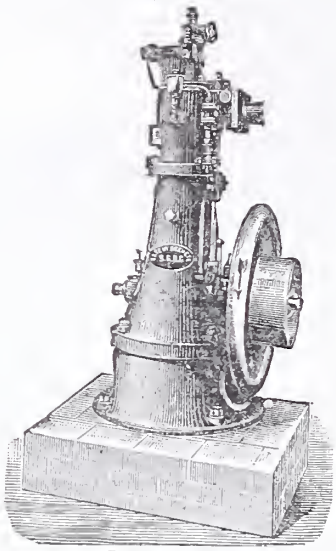
And in this situation they have *one* especial advantage over larger sheets of glass—namely, that no slamming of the door will ever be likely to crack them. At all events, there has been no breakage since they were first put in, and, possibly, there never will be.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 92.—Capitaine's New Petroleum Engine.

I HAVE been asked to call the attention of readers of WORK, and especially those who are interested in motors and wish to avail themselves of a cheap machine, worked by oil, for generating motive power, that a new petroleum engine (Capitaine's patent) has been recently introduced into this country and, I am informed, has met with the approval of all who have, as yet, seen it at work. The engine, as may be seen from the accompanying illustration, is of vertical type, and has a crank shaft at the bottom. Its construction is such as gives a noiseless and steady motion, without any vibration whatever. Owing to the vertical arrangement the cylinder is not liable to get oval. A simple and ingenious driving-gear is acted upon by the governor placed within the driving pulley, and the introduction of oil is therefore regulated automatically by the work done. The space required for, and occupied by, the engine itself is very small. After having been started, the engine does not require any attendance until the oil tank is emptied. Ordinary lamp oil is used as fuel. No electric spark is required for effecting the ignition, as *one* lamp fed with petroleum is used for vaporising the oil and igniting the gas mixture. The consumption of oil is about from seven-tenths of a pint to one pint per actual horse-power per hour, according to the size of the engine. I am told that an extensive use of this high speed engine is being made for agricultural purposes, as well as for electric lighting, driving ventilators, propelling small launches, for working cranes and hoists and capstans on board sailing vessels, etc. The cost of Capitaine's New Petroleum Engine is but little more than one-half that of any other oil engine. The agent in the United Kingdom is Mr. Leopold Tolch. These new engines are now to be seen working in Liverpool.



New Petroleum Engine, Capitaine's Patent.

### 93.—Minnitt's Patent Double Grip Lock Nut.

This new and ingenious invention by Mr. H. Minnitt, which has been recently patented and described at length in Specification No. 17,799, is, as will be readily recognised from the illustrations, given in elevation, section, and plan of one of the nuts in Figs. 1, 2, and 3, especially suitable for railway fish plates, agricultural machinery, and in all cases where there is much vibration. There are two forms of nuts employed, the parts of which are lettered respectively B, C, and B′, C′, in Figs. 1 and 2; and these nuts are used in the following manner, the two parts being called respectively in each form the cap nut (B and B′) and the cone nut (C and C′). The cap nut (B or B′), whichever form may be used, is first slipped on or over the bolt A against the plate which it is desired to tigthen up, and the cone nut (C or C′) is then screwed on the bolt and *into* the cap nut. Being provided with a saw-cut which entirely severs the cone nut on one side, the pressure of the cap nut, as the cone nut enters it, causes compression on the latter, and thus forces it to grip the bolt after it has been drawn up tight. This prevents it shaking loose through vibration. The cone nut, and the cap nut as well, are made in two forms, as already said, and as shown in the illustrations as No. 1 and No. 2. No. 1 is shown with the cone screwed and the cap nut threaded inside to take it. No. 2 shows only a plain cone, and in this case, as the nut C is screwed on the bolt, it forces itself into B, and is thus subjected to compression. In Fig. 3 another form of C′ is shown, as seen in plan from below, C″ being the plan of C′ as seen from above. As made in the manner shown in Fig. 3, the cone cap, instead of being provided with only one saw-cut by which it is entirely cut through from the outer to the inner surface, has three or four cuts extending only the length of the cone, and stopping when the hexagonal portion is reached. It is, however, used in the same manner, being screwed on the bolt after the cap nut is put on, and forced into the latter, thus causing the wings to tighten on the bolt. The nut shown in Fig. 3 can be made with screwed or plain cone. THE EDITOR.

**Minnitt's Patent Double Grip Lock Nut. Fig. 1.—Elevation; and Fig. 2.—Section, showing two Forms of Nuts—A, Bolt; B, Cap Nut; C, Cone Nut; C″, Nut C′ in Plan seen from above. Fig. 3.—Another Form of C′ as seen from below (C″).**

# SHOP:

## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Sussex "Trug" Baskets.**—The Redonda Phosphate Co. (*Montserrat, West Indies*) write:—"There is some demand here for baskets of the following measurements (inside): Length, 20 in.; width, 16 in.; depth, 8 in. This is the size of the 'oak-spelk hand coal-baskets' imported from England. They are identieal with those used by coal-porters, exeept the iron hooping. Those we have, the iron hoop is riveted to the rim and erosses on the bottom. They need be *very* strong to stand the rough usage here. I will explain the use we make of them. The phosphate—a hard, very *sharp*, eompaet rock—is quarried by the men in places where it is very difficult to erect any kind of machine. Boys are employed to fill the baskets with the rock and carry it from the quarry to the shipping place—a distance of about half a mile. The load is about 70 lbs."—[Clog and Trug Basket manufacturers will probably follow Captain Cuttle's praetice, and make a note of this.—Ed.]

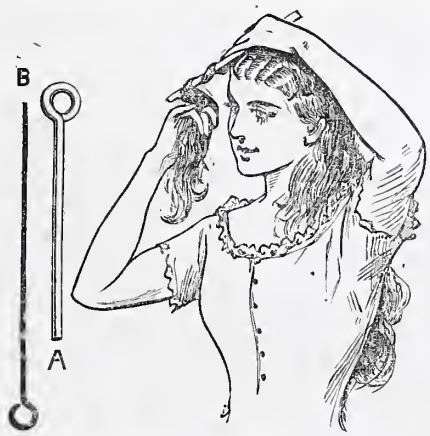
**Diamond Chips.**—F. W. (*De Beauvoir Town*) writes:—"The answer given eoncerning diamond ehips by Damon (see Work, No. 138, p. 541) might be clearer. He says that bort is almost, if not quite, as hard as diamond. Now, bort *is diamond*. Technically, real bort is somewhat harder than ordinary diamond. It cannot be cut and polished like ordinary diamond; but what is known to the trade as bort are diamonds which are too flawy or off-coloured to cut for jewellery purposes, and is, when crushed, used for slitting crystal, pebbles, etc.; made into powder for polishing hard stones, such as rubies, sapphires; and also used, when broken into small pieces, for drilling glass and china. They are the pieces known to ehina-riveters as 'diamond sparks,' or, as your correspondent puts it, 'diamond chips.' I might also mention that the material black diamond is known to the trade as carbonate, or carbon. It is black, and it eanuot be cut or polished: used principally for turning emery wheels. It is better than diamond for glass and ehina drilling, for it never wears smooth, like the diamond: it maintains its rough surface to the last. Both diamond or carbon sparks ean be obtained from firm mentioned by Damon—viz., Woods & Toussaint. I might mention that carbon is double the price of diamond."

**Wire-Work.**—Erratum.—J. S. (*London*) writes: 'On p. 534, No. 138, line 18, column 1, 'right hand' should be substituted for 'left hand.'"

**Mechanical Voting.**—J. S. (*London*) writes:—"*Re* your remarks on Mechanical Voting in No. 138, contained in 'Hints to Inventors,' I take the following from a journal I read weekly: In the Italian Parliament the voting is said to be done by electricity. Three buttons, marked 'Aye,' 'No,' and 'Abstain,' on each member's desk, are connected with a central printing apparatus, which records the votes automatically as the members touch the buttons. Doubtless, something similar would answer for the voting alluded to."

**To Restore a Damaged Mirror.**—G. A. S. (*Edinburgh*) writes:—"Judging by the number of inquiries in the columns of 'Shop' as to how damaged mirrors may be re-silvered, I think that some easier way than re-silvering may be very welcome to many readers of Work. As has been already pointed out in 'Shop,' the process of re-silvering is too difficult a job for most amateurs; and it will be found more profitable, where the plate is worth the expense, to send it to the professional. But the object of the present paper is to show whereby a small plate—say, 15 in. by 12 in.—on which the silvering is run or has been scratched, and in its present state is generally unsightly, may be made, with a very little expense, a thing of beauty and (to the owner, at least) a joy for ever. As mirrors don't all get damaged in the same place, it would be useless and out of place to lay down any hard-and-fast rule to go by, so we must leave a great deal to individual taste: the intention being to make, by the use of scraps, an imitation of a hand-painted mirror. I suggest a lake or river scene; but that is on the supposition, as well as for the sake of example, that the mirror is damaged round the sides only. For material, we require the mirror, which may be some old dressing mirror, or one which may have seen better days in the back of a case, but, having been exposed to damp, or carelessly laid past, has had its silver back partially destroyed. Then we will require some scraps, such as foliage, water-lilies, flying birds, swans, and boats (these should be in duplicate), a little starch-paste, and a dip of varnish or paint. Laying the mirror on its face, we select the scraps which we think will best suit. For the sides we take the foliage: this may take the form of a tree, or hanging ivy, or a clump of tongue fern; with a little weak paste we stick the scrap, face down, so that it covers the damaged parts; in the same way, stick on the top the flying birds, and on the bottom the water-lilies, swans, or boats, or whatever you may think will suit best. The proper placing must, of course, be left entirely to the taste of the worker or the needs of the mirror. Next paint over the scraps, going particularly into the edges, with a little lamp-black, or some dark colour, mixed with a little paste or size; or with a sharp instrument cut close round the margin of the scraps: the object being, when the scrap is removed, to leave a clear outline. Now with a sharp penknife scrape off the silver which has been covered by the scraps, keeping as sharp an outline as possible, and getting the glass quite clean. The scraps we have taken off will probably be destroyed; at any rate, they should not be used again, as the second coating of paste on the painted surface might cause them to peel off. Therefore, we take duplicate copies, and, pasting them on the face with starch-paste, or any transparent paste or gum, we place them in the spaces scraped out for them. Give the whole of the back a coat of size or starch-paste, and when dry, a coat of varnish or oil-paint. Should the scraped-out spaces be too large for the scraps, use oil-varnish; and when it has set—which will be in about three or four hours—dust some silver-bronze over the bare parts; and if your scraps have been laid on with taste, you have a good imitation of a hand-painted mirror."

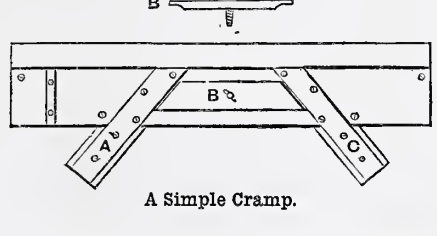
**A Simple Hair Curler and Crimper.**—F. H. (*Battersea*) writes:—"Perhaps some readers of Work will think anything appertaining to hair curling out of place, but I am describing an appliance which, as it is very useful, and is very simple to make, will be none the less welcome for being first made public through the pages of Work. A is a



Hair Curling and Crimping Appliance.

piece of ¼ in. iron gas-pipe about 12 in. long, bent to form a handle: it is filed and burnished; B is 18 in. of ¼ in. iron rod, used as the heater. It is placed in the fire and made red hot, and then inserted into the tube A for a few minutes. By this means there is no fear of the iron being hot enough to singe the hair, and it is always kept bright. The female figure explains how the appliance is used."

**A Simple Cramp.**—Markwell writes:—"One of the first things I made, soon after Work first appeared, was a mitre shooting board and cramp combined. By its aid, sundry frames which I made have been comfortably tapped together. In the illustration below, A, B, and C are made of hard wood. I think J. W. would like it better than his. The angle-piece is rabbeted, and the rabbet lined with



A Simple Cramp.

leather. When screwed strongly down, English gilt moulding is not injured, and brads may be used; but I must say I like the idea of screws. A little chalk on the back of moulding, and also on board, is useful. I put my shaded lamp a few inches from the mitre points, and can at once see if the joint is quite close front and rear. By unshipping A, B, and C (often done), an ordinary shooting board is available."

### II.—Questions Answered by Editor and Staff.

**Rubber Types.**—E. M. (*London*).—Climax date bands may be made by forming a sufficiently deep mould, the surface of which should be carefully levelled, and using two or three thicknesses of raw sheet rubber compo, backed with one thickness of linen, the die being cut into suitable strips, and the strips cemented end to end with rubber cement after vulcanisation. Solid rubber type may be made in a similar manner (omitting the linen), and cut with a keen knife-blade, wetted with water, to the desired length. Rubber-faced type cannot be made with appliances available to an ordinary amateur.—Qui Vive.

**Fretwork Enlarged.**—R. M. (*Penicuik*).—The designs drawn full size have often to be reduced to fit the space available in Work, when so many conflicting tastes must be represented. To enlarge patterns there is a simple mechanical contrivance known as the pantograph, which any cyclopædia will explain. Unfortunately, it would take up too much room to do it here. "Letts's sectional tracing paper" provides another way. You trace the design on a sheet ruled in tiny squares of red lines, and then, by a mechanical process of counting squares, you copy it on one of much larger scale. This is easier to do than to describe; but if you have seen anyone working the old-fashioned Berlin wool work from a small pattern, you will gather the ruling motive of the process. For your kindly words anent Work, and the censure of dilatory agents, compressed thanks in a few words, but none the less real.—G. W.

**Panel.**—Cartridge.—The basket-work or dotted effect of background in patterns in low-relief carving is gained by hammering the ground with punches sold for that purpose at any tool-maker's. The commonest one of simple lines in a square produces the wicker-work pattern.—J. G. W.

**Patent Agents.**—W. G. S. (*Bristol*) is strongly advised to place himself in the hands of a patent agent in his own city. It is important that the patentee should be near his agent. We are unable to recommend anyone at Bristol, and it would not be safe to take a name from a directory merely. W. G. S. might place himself in communication with two or three local patentees (whose names he could get from advertisements, or from their articles), and take their opinions as to the best agent. Among London agents, we may mention Rayner and Cassell, 37, Chancery Lane, W.C., and Messrs. Carpmael & Co., Southampton Buildings, Chancery Lane, as of high professional reputation. Judging from our own experience, as well as from common sense, we incline to think that Mr. Eustace Smith's remarks are calculated to give too low an idea of the value of provisional protection.—C. C. C.

**Blue Prints.**—Cosmos.—The following formulæ will answer well:—

| | | |
|---|---|---|
| Ferricyanide of potassium . | 70 grs. | No. 1. |
| Water . . . . . | 1 oz. | |
| Ammonio-citrate of iron . . | 100 grs. | No. 2. |
| Water . . . . . | 1 oz. | |

Mix equal parts of 1 and 2 just before use, and apply evenly with a brush or sponge, and dry in the dark.—D.

**Toy Wheels.**—J. M. C. (*Greenwich*).—You would, I think, be able to buy your toy bassinette wheels of The Victor Cycle Co., Grimsby, Yorkshire, who advertise in Work, and who would be able to get them for you if ordered. The price of a set of wheels 11 in. by 7 in. would be about four shillings, or a little over, as I am able to procure a small-sized set 18 in. by 12 in., for an ordinary bassinette, at five shillings and sixpence the set, wholesale price, in Manchester.—W. P.

**Wheels.**—G. H. A. (*Sheffield*).—The proper address is The Victor Cycle Co., Grimsby. I know of other makers, but as they do not (unlike the Victor Cycle Co.) advertise in Work, I do not think it fair to mention them, but by writing to the above address you will receive every attention.—W. P.

**Ice-Cream Freezer.**—J. C. (*Belfast*).—Glad to give you any information in my power; but I do not see the point of your terming yourself a "man of wood," as these freezers are made out of a very different material. They are, or ought to be, made of pewter, and, as a rule, are about twice as deep as the diameter of them. The sizes vary according to the quantity required. You say you want to make a sufficient quantity to dispose of in your shop. I think, when you look at it, that seems rather vague. I cannot tell whether your shop is a large or small one, or whether the Belfast folk are fond of ice or not. But to return to the subject. If you can use a soldering iron, it is not a very difficult job to make an ice pot. Get a piece of sheet pewter, 15 × 10; turn it round on a wooden mandrel; let the edges "butt"—that is, just meet—and, with a hatchet soldering iron, solder down the seam on the mandrel, using resin and oil as a flux, and pure solder. Do not try to make the solder flow after the iron, and never mind if it looks rough. After you have soldered the seam down, rasp off all superfluous solder till it is level with the metal, and then scrape smooth with a knife or piece of steel. Then cut out a bottom that will just slip in, and solder that round in the same way. Turn a piece for the rim of the cover, 1½ in. deep, and solder this, and make it smooth at the seam inside and out, so that it will fit well. Put a cover on this, the same as you did the bottom. The shop ones are hollowed up; but that is not essential. Lastly, bend a piece of ⅜ in. tin pipe across the cover, and solder it to each side,

for a handle, and the affair is complete. For instructions in soldering, see Nos. 19 and 23.—R. A.

**Furniture Restoring.**—PAPYRUS.—I am afraid you will not be able to improve the appearance of your mahogany chairs by ebonising them; or, perhaps, it should rather be said that such chairs as I gather yours are would not look well ebonised. I make these remarks, as you ask for any suggestions; but it is certainly possible to ebonise your mahogany chairs. If they are good wood—*i.e.*, finely figured, and of a good colour—it would be a great pity to blacken them; for, though you object strongly to mahogany colour, the probability is that most of your friends will object more to the black. Of course, if your chairs are the fiery red so often considered to be the true mahogany colour, do anything you like to them; you can't make them more unsightly than they are. This may be a consolation to you, and you may adopt several different courses. If you want to ebonise them thoroughly, all the existing polish must be removed, either by washing off, or scraping, or papering, or perhaps a little of all three. Then stain, and re-polish in the usual way. If this seems too tedious, polish them with blackened polish, which you may make by mixing gas-black in ordinary French polish. This, of course, is not such a satisfactory way as the other, as the stain does not enter the wood, but is merely on the surface, from which wear will remove it. If you want an easy way of darkening the wood, not blacking it, use French polish with some brown in it. It is quite impossible to restore faded and worn leather chair coverings to their pristine appearance; but if not too far gone, and you are skilful enough, it is possible to improve and, to a certain extent, to obliterate the marks of wear and tear. Unless you are careful, though, you are more likely to do harm than good. The only way is to go lightly over the leather with a rubber just moistened with thin French polish or white of egg. Without seeing the things, it is impossible to answer your further query as to the desirability and economy of re-covering the furniture. Your own judgment, or the decision of an experienced upholsterer, after he has seen the coverings, will be more reliable; but your idea of covering things which have leather seats—and are, therefore, probably dining-room chairs—in cretonne, is peculiar. Why not use something which will not be so *outré*? There is leather-cloth, which so closely resembles leather that at a very short distance the difference could hardly be detected. Be careful, though, to get only the very best quality. It wears for years, and is cheap enough for anything.—D. D.

**Plush on Brackets.**—F. C. (*Belfast*).—As I have not seen the frame to which you refer, I cannot say whether the plush was glued or backed on, though you might have noticed for yourself. The plush having been put on well is only owing to the skill of the worker. We cannot give you this; and I very much fear that what hints I can give you will not avail you much. However, that is your look-out. Plush may be put on frames by gluing the wood either all over or just at the back, so as to fix the edges on behind. At the bends and angles on the inner edges of the frame cut the plush neatly. Do not apply the glue to the plush, which should not be pressed down too hard: only enough to cause adherence. If you ask at any good cabinet-maker's, you will be able to get suitable plush. Ask for silk plush, and at the same time ask the price, which depends on quality. You might get the sconces (the brasses to which you allude) at the same place, or from any shop dealing in cabinet-makers' brass-work. If you do not know any, write to Grew and Bridge. How can I tell you the price of the brasses you saw? You might as well ask how big a piece of stone is.—D. D.

**Wood-Wool Making Machine, and Folding Furniture Designs.**—G. D. (*Oldham*).—You must forgive me if I create disappointment by saying that I am entirely ignorant of the article you are in quest of; viz., wood-wool making machine. I have made inquiries among my friends and relatives, but fail to elicit any information likely to be of use to you. Perhaps some reader may peruse this somewhat "queery" reply who, perchance, is fully acquainted with the above article. If so, I shall personally thank him if he will be so good as to forward the fullest particulars, for the benefit of yourself and others. There is one query, however, which I am glad to say I can reply to. Several designs of folding furniture have been given by various contributors, including myself, in the volumes of WORK so far published. You will, doubtless, have seen the announcement that Indexes to WORK are obtainable, at the cost of 1d. My advice is: get one at once. Therein you will find specified several folding furniture designs. You will find two folding arm-chairs and three folding tables, by me, in Nos. 41 and 37 respectively; and in No. 23 are also three designs of folding chairs. I must inform you, however, that it came to light, after the publication of the latter, that Fig. 3 design represented an article which is patented in this country (see p. 476, No. 30). My fellow contributor was unaware of this fact when he sent the designs in. I mention all this that you may not infringe the patentee's rights by making this particular chair. You need not fear to progress with any of those (folding or otherwise) which I have given, as I make a point of giving original designs. The price of volumes of WORK, bound, is 7s. 6d. If you possess any skill, however, I should advise you to endeavour to bind back numbers yourself by reading the articles on Bookbinding, commencing in No. 57.—J. S.

**Portable Photographic Studio.**—R. H. (*Bishop Auckland*).—It is impossible, in the space at our disposal in these columns, to do more than give a mere sketch of how to build a studio. In the first place, much depends on the site and the surroundings; and, secondly, the amount of money to be expended. A "portable studio" is a very elastic term, and may mean anything between lath and canvas and brick and glass—in fact, anything else. "Portability" is a term signifying not *permanently attached to the ground* or *adjoining buildings*, and may cost, so to say, anything according to size, material, and decoration employed. A home-built small studio—say, 20 ft. by 12 ft.—might be made for £8 to £10; but it could only be roughly finished. Supposing the site available is an open space, not shaded with buildings, make eight or ten piers of bricks, about a foot high, as a support for the superstructure, and to provide ventilation under the floor for dryness' sake; and on these piers lay a frame that will enclose a space 20 ft. by 12 ft. of 4 in. battens. Lighter wood will do for the uprights and roof. The walls may be made of match-boarding, and the roof of the same, covered with roofing felt. One side, that towards the north, may be glazed, and also the north side of the roof; one corner inside to be partitioned off for a dark room; backgrounds to be fixed at each end; the whole of the framework to be *screwed* firmly together, not nailed; provision for a door on the unglazed side to be made where

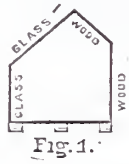


Fig. 1.

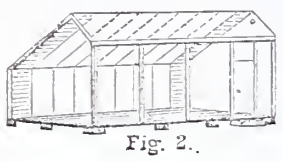

Fig. 2.

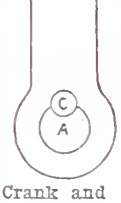
Portable Photographic Studio.

most convenient. The floor should be made of good stout planks, tarred on the lower side. *Any* kind of picture can be taken in such a studio, the kind being regulated by *the lighting*, which is controlled by blinds, that should be contrived to cover the whole of the glass, and easily opened and closed, according to circumstances. The woodwork of the walls may be made more sightly by stretching canvas over them, and papering; and the floor should be covered with floorcloth, and a few curtains disposed here and there, to give an air of comfort otherwise absent. A few coats of paint on the outside will be a useful protection. The subjoined diagrams will show the shape and general design of the place. Fig. 1 is a sectional end view, showing the slope of the roof; and Fig. 2 showing door and arrangement of the glass, the wooden side being towards the spectator. Ventilators should be placed near the ridge at each end, and of course, in a slight sketch like this, many details are, perforce, omitted. The above gives a general idea of one of the most useful forms. Many little matters will suggest themselves, when the place is set up, as conveniences or improvements, according to the taste or funds of the proprietor. Reflectors, furniture, head-rests, etc., are necessary accessories. The dark room should be lighted from the outside, and extra ventilation provided for it. A deep wooden sink, covered with sheet lead, is practically best, there being less danger of breakages to bottles, measures, etc., than if stoneware is used. There should be plenty of shelf room, and space to lay down the dark slides for filling and emptying; and, it goes without saying, total exclusion of daylight.—D.

**Safety Bicycle.**—H. W. (*No Address*).—I rather think H. W. will find that the crank is not *screwed* on to the shaft A. The screw that appears behind the crank is for the nut to adjust the bearing. Neither is it usual to have the key C round as shown, as that sort of key works loose much sooner than a rectangular one. If this crank is really screwed on, the other will do so, and they would be screwed right and left screws. The pin C may possibly be screwed as well; in that case a *nick* would have to be made in the end of it to unscrew with a screwdriver, then the crank would screw off. If the crank is on plain it may be wrenched off with a crank-puller, used by repairers. The best thing to do is to give the job to a repairer.—A. S. P.



Crank and Shaft.

**Patenting an Invention.**—H. W. (*Nottingham*).—If the machine is to be worked by downward pressure of the hand (a succession of blows), and not by a wheel, the idea, so far, is not new. We have been shown such an apparatus, its price being, I believe, 1s. 6d. Before incurring expense, H. W. would do well to ascertain that nothing with which his own machine would clash has been protected. Perhaps he could not do better than make a model, and submit it to Mr. Clarence S. Newton, General Business Agent, Royal Courts Chambers, 70, Chancery Lane, W.C. From him he will get information on the above point on what the commercial chances of his invention may be worth, and so forth. Communications with such an agent would, of course, be considered confidential; but if the inventor fears piracy, he can first get provisional protection. As to the third query: till H. W.'s orders become large, we do not see that he can do better than buy his spools of cotton in such a cotton-consuming place as his own town. For needles, he might go to F. G. Heath & Co., Crabb's Cross, Redditch; and for light brass tubing to Stone & Benton, Birmingham.—C. C. C.

**Stain for Blackboard.**—A WELL-WISHER.—Much information upon this subject appears in the following back numbers of WORK: 39, 44, 98, 102, 103, 104, which may be obtained through any bookseller, price 1d. each.

**Globe.**—EQUATOR.—I doubt whether you can get what you require; but you might inquire of some map publishers, as Philips & Son, Fleet Street; Stanford, of Charing Cross; or W. & A. K. Johnston, 5, White Hart Street, Warwick Lane, E.C.—F. B. C.

**Concert Flute.**—NORTHAMPTON.—There are about a dozen different bores, and as many systems of key arrangement in flutes, in each of which the holes are differently laid out, so that it is impossible to help you. Your only plan would be to get a flute of the pattern you wanted and work to it. We may tell you, however, that the arrangement of the holes on the conical-bore flute is altogether different from that on the cylinder-bore instrument.—G.

**Makers of Copying Apparatus.**—W. O. J. (*No Address*).—A reference to Kelly's "London Directory" will give the information wanted.

**Bois-Duré.**—J. S. (*No Address*).—If this is the material we take it to be, it is wood fibre condensed by heavy pressure, and has been patented. We believe that Mr. T. Remus, Tabernacle Street and Castle Street, Finsbury Square, London, supplies it in combination with his patent angle-brasses. Possibly, J. S. might do well to apply to him.—S. W.

**Making Small Still.**—DEVON.—In WORK, Vol. II., pp. 490 and 651, Nos. 82 and 92, you will find a full description and particulars of a small still that, I think, will answer your requirements. The answers are at full length, and I think you would have no trouble in making one from these instructions.—R. A.

**Brazing Bicycle Tubes.**—BRASSY.—If BRASSY will provide himself with the numbers of WORK containing papers on the "Construction of the Safety Bicycle," he will get all the information as to brazing he can possibly desire.—A. S. P.

**Affixing Glass Letters.**—GLASS.—If I had this to do I should simply use the best varnish, covering the letters well, and when nearly set, giving another coat round the edges to fill up all holes, so as to keep out damp and moisture. There is a very good cement in the market, called "Coagiline," also Le Page's liquid glue. If you use either of these I should still put a coat of varnish round the edges. If it does not matter to have it transparent, you will find red lead thinned with varnish answer well; or the following: Litharge, two parts; white lead, one part: boiled linseed oil, three parts; gum copal, one part; mix just before using; or you could use red lead thinned with varnish.—W. E. D.

**Eidograph.**—NIL DESPERANDUM.—I am unable to give the required directions, but NIL DESPERANDUM will find the instrument (which is an improvement on the pantograph) illustrated and described in Knight's "Practical Dictionary of Mechanics," p. 775, published by Cassell & Co., London, E.C.—S. W.

**Waterproofing Cloth.**—J. B. (*Hastings*).—Our correspondent does not tell us what material it is he desires to waterproof, therefore we cannot give him any satisfactory information. If it is woollen cloth, then one kind of treatment has to be adopted; if it is flax, cotton, or other vegetable material, then another plan has to be adopted. What will be correct for one material will be quite inapplicable to the others. If he will state specifically what he wants to do, we may then possibly be in the position to give him the required information.—C. E.

**Quarter Horse-Power Engine.**—G. M. L. (*Selborne*).—You are quite right, it would be most convenient to have full-size drawings of the engine to put up on the workshop wall, or on a board, to go to for measurements. In fact, it is almost necessary. Whether such drawings will be supplied, I cannot say as yet, but the very best preparation for making the engine would be to make full-size drawings from the scale drawings in WORK, taking the *written* dimensions wherever possible. Before very long, I think, the castings will be advertised; you will then be able to make the drawings well and carefully: the time will not be wasted, even if drawings are eventually supplied, since it is sure to give the workman a better knowledge of what he has to do, and will save him from making mistakes.—F. A. M.

**Mechanical Office Work.**—F. H. B. (*Manchester*).—You should advertise your requirements in WORK. Any writings you care to send, on approval, will be considered, if suitable for WORK. London is already overcrowded with workers, and, as you are in a manufactory much in your own line, the best thing you can do is to stop there, and make such headway as you can in business and out of it; but don't come to London.

**Photo Frame in Fretwork.**—NO NAME.—Your large design, as you have made it up, looks well, and shall be published if I can make room for it, but you have sent your letter and large sketch without name, initials, or *nom-de-plume*, so

I am unable to follow the above side-heading with one or the other of these in the usual way. Kindly send your name and address.

**Battery for Electric Night Light.**—LUX IN TENEBRIS.—I cannot advise the use of a chromic acid or bichromate battery in a bedroom for supplying current to a small electric lamp used on electric night light. Although the fumes from such batteries are said to be non-injurious, the odour from them is to me objectionable, and is highly injurious to my brother, causing sore throat and constriction of the bronchial tubes. The large agglomerate tin block Leclanché is very suitable for a night-light battery; so is the Gassner dry battery of large cells. It would take six such cells to light an 8-volt lamp. The cost of the Leclanché battery at 10s. 6d. each cell will be three guineas; the cost of the Gassner at 5s. per cell will be 30s. Mr. K. Schall, Wigmore Street, London, W., supplies a 6-cell chloride of silver battery, specially made for small electric lights, at a cost of £2 9s. These, although costly, are clean and portable. A correspondent at Ipswich has made his own Leclanché battery for an electric night light. The agglomerate Leclanché and the Gassner can be obtained from Messrs. T. Gent & Co., Faraday Works, Leicester, who also supply lamps and other electric light appliances. You can also, as you suggest, get everything from Mr. Bottone, who is agent for a very good portable dry battery. Replying to your questions as they stand in your letter: (1) Large cells, carbons, zincs, etc., in a battery, lessen the internal resistance and furnish a larger volume of current, lasting for a longer time than the current from small cells. (2) Amalgamating the zinc with mercury means coating the cleaned zinc with this metal to prevent waste by excessive or local action. (3) Either of the firms mentioned can supply carbons, zincs, clamps, switches, wire, and lamps, and will quote you prices for the same. I do not know a firm in Dublin. (4) A sickly odour, to me, proceeds from a bichromate battery, so I would not have one in *my* bedroom. This objectionable feature does not exist in the Leclanché, Gassner, and chloride of silver batteries. The Lithanode battery of Messrs. Cathcart & Peto, Hatton Garden, E.C., is also free from objectionable fumes. A battery may, however, be left outside, and the conducting wires only led into the room. (5) A battery would need recharging about once a week, if you use the light for from ten to twenty minutes at a time, about a dozen times in the night, as this would mean at the least two hours per night. I thank you for your kindly appreciative words respecting WORK and members of the editorial staff. We endeavour to couch our instructions in "good Anglo-Saxon language," and hope you may long enjoy, as a subscriber, some more half hours with us.—G. E. B.

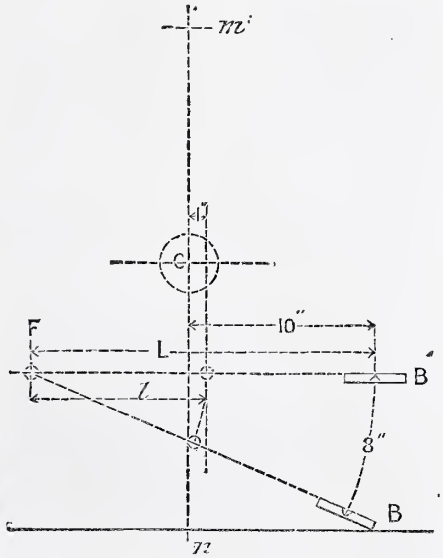
**How to Make a Dynamo.**—J. G. (*Edinburgh*).—Articles giving illustrated instructions on making small dynamos appeared in Nos. 92, 94, 97, and 99, published December 20th, 1890; January 3rd, January 24th, and February 7th, 1891. An article on accumulators appeared in No. 101, published on February 21st, 1891. "The Dynamo: How Made and Used," by Mr. Bottone, Wallington, Surrey; and "How to Make a Dynamo," by Mr. A. Crofts, Dover, are both good books on the subject, well suited to the wants and knowledge of amateur dynamo makers.—G. E. B.

**Battery for Medical Coil.**—T. A. (*Shotley Bridge*).—Yes, a Leclanché battery can be, and is, used for working medical coils, but special large cells should be employed. The large 6-block agglomerate cells are suitable to this work, but their cost (10s. 6d. each) is rather high. The Gassner dry battery has also been employed for this purpose. Messrs. T. Gent & Co., Leicester, supply these and other suitable batteries. The new chloride of silver cells made by Mr. K. Schall, Wigmore Street, W., will give a strong constant current for several hours whilst working a medical coil. If the coil has to be used for from 1 to 1½ hours each day it will be necessary to frequently charge the battery—say at least once a week.—G. E. B.

**Battery for Firing Fuses.**—W. K. S. (*Whaley Bridge*).—If you know anything about the construction of electric batteries, and can make them yourself, you may get all the materials and instructions from Mr. Bottone. You will have to tell him just what you wish to do, the kind of fuse you wish to fire the shot with, the distance of the battery from the fuse, and size of the conducting wire to the battery. He will then tell you what things to get and how much they will cost. Messrs. King, Mendham, & Co., Western Electric Works, Bristol, make a special battery of 8 cells for this purpose at a cost of £4.—G. E. B.

**Incandescent Gas Light.**—R. C. B. writes respecting the address of the Incandescent Gas Light Co., given in No. 134, p. 475, Vol. III., of WORK, in reply to C. N. V. (*Aldershot*). He says the address is not the one C. N. V. wants, but he shall be very pleased to let C. N. V. know the address or anything else about the light. I should have been better pleased if R. C. B. had given me the proper address, and the information offered, so that it could have been published for the benefit of all readers of WORK.—G. E. B.

**Lathe Proportions.**—WALLACE.—The dip or throw of a crank is not measured over all, but from centre of shaft to centre of pin. Assuming your square crank-shaft to be 1 in. square, then the throw of your crank would be 4 in. and the stroke would be 8 in. Now 8 in. is just about the proper stroke for the footboard to move up and down; for a small 3¼ lathe, 7 in. will do, but for a 5 in. you require a little more power; a greater rise of the footboard is more fatiguing for the leg. You could not with this crank use the ordinary kind of treadle, as it must nearly double the stroke of the crank, and I think you should give it up. The proper throw for the crank is determined by the movement it is desired to give to the foot (say 8 in.), and the proportions of the lever arm of the treadle. In the sketch sent herewith, *m* is the centre of the mandrel; *m n* a perpendicular dropped from *m* and passing through the centre of crank-shaft at C; F is the fulcrum of the treadle; B B the footboard, the centre of which should be 10 in. in front of the perpendicular centre line; L is the full length of the treadle lever, and *l* is the short length measured from fulcrum to the point of attachment of pitman or crank-hook; this point of attachment is rather better placed 1 in. in front of the perpendicular, as it lengthens the down stroke when the lathe runs forwards. F is rather better placed 6 or 8 in. high, because then, in descending, the foot moves a little forward, which is somewhat easier. Now if L be twice as long as *l*, then it is evident the throw of the crank will have to be 2 in. and the stroke 4 in. If the crank had a throw of 2¼ in. and a stroke of 4½ in., then the fulcrum would be moved back 2½ in., or more exactly 2⅞ in., so as to make L = 20½ in. and *l*



Sketch of Treadle Arrangement.

=11½, in order that L may bear the same proportion to *l* that 8 does to 4½. You will see from all this that 2¼ is a proper throw for a crank if the other parts are made in proportion. With regard to your second question, I have never seen a weaver's shuttle tip, and cannot tell whether it would do to insert one in each end of the crank-shaft to form a point on which it would turn. To do this the pin must be at least ⅝ in. diam., or it might break right off; also the angle of the cone should not be more obtuse than 60 degrees. I should prefer to bore a ½ in. hole up each end of the shaft, and insert a hard steel plug 1 in. long, having a ⅛ in. hole bored right through the centre and countersunk to 60 degrees at the outer end; plug to be driven in tightly, and the hole in the centre to form a reservoir for oil. The screws on which the crank-shaft turns may be ⅝ in. diam., screwed with a Whitworth thread and pointed to exactly 60 degrees so as to fit well into the holes in the crank-shaft; these screws can be tapped into the beech wood standards so as to fit pretty tightly, and they will hold very well without any metal plate or backnut. If you are 5 ft. 6 in. in height, your lathe centres, from the floor, should be about 3 ft. 6 in.; if higher you will get too many chips in your face; if lower you will not see so well. The top of your lathe bed will, therefore, be 3 ft. 1 in. high. It would not do to incline the connecting rod or pitman 30 degrees, as you propose, but it may be inclined a little, as shown in the Fig. I send; the effect is to lengthen the down stroke and make the foot rise rather faster, which is an advantage in running forwards, but a disadvantage when running backwards, as you want to do in sand papering.—F. A. M.

**Electric Detector.**—MINING DETECTOR.—You evidently have an ordinary linesman's current detector or galvanometer with the dial marked in degrees of the arc of a circle, numbered from 1 to 60 on each side of zero. When you send the current from one cell of a battery through the instrument, the needle is deflected to 30 degrees; with two cells you get a deflection of 50 degrees; and with three cells you get a deflection of 60 degrees. Now you wish to know the value of those degrees. I fear that I shall not make the value clear to your mind by stating that it is "as the tangent of the angles of deflection," so will try to simplify this statement by saying that the value of the deflection increases disproportionately with the distance of the needle point from the zero mark. From 1 to 20 the degrees will indicate proportional strength of current passing through the instrument—that is to say, a deflection of 20 will indicate a strength twice that of 10. But, from this upward, we may put down 30 as 15 × 2 + 3·076; 40 as 20 × 2 + 8·066; 50 as 25 × 2 + 18·275; and 60 as 30 × 2 + 39·220. You will not be safe in taking even these figures as being absolutely correct, since the grading on the dials of these instruments is not made to a standard, nor are the needles all made of the same weight. This short table will, however, give you some idea of the value of the deflections, and enable you to make rough approximations of the strength of the current from your cells. The use of this instrument in the hands of a linesman or electric bell fitter is to test lines for leakage of current, and to give a rough idea of the strength of a battery. For instance, he knows that the current from a cell in good condition should deflect the needle to 30 degrees. If it fails to do this, he knows that the battery is getting weak. The value of the deflections is not given in volts or ampères, but there are instruments made which are so graded as to indicate the strength of the current in volts and ampères by the deflections of the needle. Volts represent the pressure of the current; ampères show its volume, or bulk, so to speak. Thus, a current of 1 volt will represent the pressure (E.M.F.) of that obtained from one cell of a Daniell battery; whilst a current of 1 ampère will represent the volume of electricity obtained through a resistance of the ohm when the pressure or E.M.F. is 1 volt. Taking water as an analogy, the ohm may be said to represent the dimensions of a pipe, and the volt the pressure or head of water, whilst the ampère will show the volume of water obtained through the pipe. This is the nearest I can do for you in the way of simplifying these terms.—G. E. B.

**Telescope.**—T. H. (*Spennymoor*) wants to know first, "The proper method of mounting the various glasses that they may be correctly fixed in their places." From a former remark made it is evident he wishes to work with as little cost as possible, and has mentioned a paper tube. I thus take for granted he does not use a lathe. Make a cell for the object-glass thus:—Procure a piece of brass tubing large enough to take the object-glass, and cut off 2 in.: cut the ends perpendicular to the length. Anyone who has a lathe would be pleased to do this. In the next place cut a disc of sheet brass 4 in. diameter, to which solder the tube, leaving ½ in. all round. Cut out the centre, leaving the opening ½ in. less than the tube; this will form a bed for the lens to rest on. This opening can be cut with an ordinary hand fret saw. I have sawn stout sheet brass repeatedly thus. Take another piece of tube and cut a slit in it, so that it may be sprung into the cell now made. Place the lens in its cell and spring in the slit tube and the lens will be held firmly: it may be further secured by means of a bayonet joint. Four small holes must be made in the flange to take screws. Now get a turner to turn a wooden ring 2 in. wide, ⅜ in thick, and of a diameter large enough to admit the paper tube made. When the object-glass is secured by the spring in its place, it can be attached to the tube with four screws. Of course, this is rather a clumsy way, but it will be efficient and not costly. Secondly, the probable cost of an ordinary object-glass of 3 in. diameter and about 36 in. focus, also price of an achromatic of similar dimensions. An ordinary object-glass 3 in. diameter and 50 in. focus may be procured from 5s. 6d. with lenses for eye-piece; achromatic, 3 in. diameter, about 45 in. focus, from £4 to £6, according to maker and quality. Thirdly, eye-pieces. The optician supplying the object-glass would send the lenses required; they will cost about 2s. An article is in the hands of the Editor on the construction of eye-pieces, which will supply every particular needed; that being the case, I will save space here. Lastly, the best house to purchase from. Without undertaking to say which house is the best, I would say that repeatedly have I done business with Lancaster, Birmingham, and have always found satisfaction. Should T. H. not like the primitive plan suggested, and can command a screw-cutting lathe, then he will find in another answer over my initials the proper method of making and mounting cells.—O. B.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Flower-Pot Cases.**—INQUIRER writes:—"Could any of your numerous readers oblige by giving the name and address of a firm or firms where ornamental flower-pot expandible envelopes (wood) can be had?"

**Darning Weavers.**—MART writes:—"Will any reader of WORK please give me address of firm that make the Patent Darning Weaver, with price of same?"

**Wool Winder.**—MART writes:—"Will some kind reader of WORK please give me a design and the construction of a wool winder—one to stand on the table and wind the wool into balls?"

**Canoe Building.**—CENTRE-BOARD CANOE writes:—"Will some practical hand kindly answer the following?—(1) How is a canoe keel built to take a centre-board? Please give rough sketch. (2) Does the special form of keel cause any difficulty, or necessitate a different method in fitting on the first plank (or garboard streak, as I believe it is called)? If so, please give sketch, and say how difficulty is to

be overcome. (3) What thickness of wood should be used for centre-board well? How is it put together, and how is it attached to keel? Sketch would much oblige. (4) Please give the special advantages of mahogany or cedar, as compared with pine, for canoe building, and say if oak (best white English) would make much difference in the weight of the craft, or be more difficult to mould to shape. This question refers to the planking. I have no steam killer, and wish to do without one."

**Invisible Printing.**—TULIP writes:—"Could any reader tell me what kind of stuff is used to print with on cardboard, etc., that is invisible in the daytime, but can be seen in the dark?"

**Pipe Mouthpieces.**—C. H. C. (*Manningham*) writes:—"Will any reader kindly tell me how vulcanite pipe mouthpieces are polished?"

**White Metal.**—L. S. L. (*Kirkcaldy*) writes:—"Would some correspondent kindly give me some information about white metal? I am constantly coming across articles made from it, and it appears to me to be such a useful and cheap substitute for silver for many purposes, that information as to its precise composition, properties, and applications would be acceptable to many of the readers of WORK."

**Pins.**—A. W. B. (*Bristol*) writes:—"Can any reader kindly give me some particulars as to the manufacture of pins, the district where principally made, and names of two or three firms engaged in the business."

**Saw Bench.**—WOODWORKER writes:—"I have read CHOPSTICK'S note on Hand Sawbench in WORK, No. 135, p. 491, and I wish to know whether he or any of our readers can instruct me as to the making of one such as he describes."

**Taps.**—D. G. C. (*Bradford*) asks for "the address of any firm where I can buy taps made of iron exclusively."

**Handles for Driving Whips.**—E.E. S. (*Newton Abbot*) writes:—"Can any reader give me the address of a shop where I can get handles for driving whips?"

**Modelling Wax.**—CARVER writes:—"Can any reader inform me how to make modelling wax, and what articles to make it with?"

**Razor Case.**—J. A. (*Gristhorpe*) writes:—"Could anyone give me a design for a razor case?"

**Markets for Wood Carving.**—F. G. W. (*Kettering*) writes:—"I would like to know of some exhibition where I could enter a carved oak mantelpiece recently designed and executed by myself. If any of your correspondents can tell me of any such exhibition, I shall be much obliged."

**Colour Matching.**—CONSTANT READER wants to know the best book on matching colours, with colours in book, and how to make them.

**Gum.**—GUM writes:—"Will anyone please give me a good recipe for making gum liquid—something that will keep so, and without becoming musty?"

**Re-transfer Ink.**—W. E. (*Bristol*) writes:—"Can any reader of WORK tell me the way to make re-transfer ink from plate to stone?"

**WORK Exhibitions.**—YENNIL writes:—"Will you kindly say if there will be any sort of exhibition this year, or early next, where small inventions may be exhibited? I have taken out a provisional protection for an improved mangle and wringer, and should like to get it, or the improved part, exhibited."—[There will be no WORK Exhibition again for the present, but local workmen's industrial exhibitions are constantly being held all over the country. You should watch the public announcements in the daily newspapers. In the meanwhile, I shall always be glad to receive from secretaries and projectors of such exhibitions early intimation of plans and intentions in this respect, in order to give them prominence in WORK.—ED.]

**Model Yacht Fittings.**—T. H. S. (*Newport, Mon.*) writes:—"Not having seen an answer in the columns of WORK for deck fittings and rigging of model yacht, 4 ft. long, I would be glad if one of the readers would give an insight of same."

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Colouring Bright Steel Surfaces.**—H. B. S. (*Liverpool*) writes:—"BARIUM asks for a method of colouring steel articles (see p. 542, No. 138). Why not colour them in the usual way, which really means tempering them by heat? The heat required for tempering watch-springs, etc., which gives a bright blue to the articles, is only 288° C., and cannot be considered high. The method used for small flat objects is to heat them upon an iron plate until the colour is attained; then throw them into water. Mercury would cool them quicker, but would be much more expensive. A neat way of proceeding is to have an iron pan filled with fusible metal, and to heat it up to the required temperature, which may be noted on a chemical thermometer, just dipping in the metal. The articles are strung on a wire and placed in the bath, and allowed to remain in the melted metal till they have acquired the temperature of the bath, then taken out and rapidly quenched. I do not know that the latter plan has been used on a large scale—it has on a small scale—but it is worth trying. Keeping the bath at the proper temperature is the chief thing. I may say that pens are coloured by heating to the required temperature in a revolving cylinder. Perhaps the latter plan might suit you. I need hardly say that the articles must be clean and bright."

**Drilling Grindstones.**—STONEMASON writes, in reply to T. A. D. (*Royton*) (see p. 510, No. 136):—"Holes are not drilled in grindstones, but are cut by hand with a mallet and small chisels. The chisels must be kept sharp. It is a stonemasons' job, and I should never attempt to drill holes in grit-stone. Before cutting holes in thin stones, they should be fastened down on another stone with plaster of Paris."

**Measurement of Paraffin Barrels.**—H. B. S. (*Liverpool*) writes, in reply to PARAFFIN (see p. 526, No. 137):—"I think you will find that the '120 tests,' marked on the barrels, has nothing to do with the measurements of the barrels. It evidently alludes to what is known as the 'flame test,' which is conducted in the following manner: A small quantity of the oil, contained in a metal cup, is heated in a suitable manner in a water bath. In the oil is immersed the bulb of a thermometer. At short intervals a lighted taper is passed over the surface of the oil, and when a flash of light is noticed, the oil is giving off inflammable vapour, and the temperature is noted. In your particular case the oil gives off an inflammable vapour at 120° F. This test is necessary, as some of the oils give off an inflammable vapour at little above the ordinary temperature, and these oils are very dangerous. It is required by Act of Parliament that oils of this description should be called petroleum."

**Lapidary Work.**—H. B. S. (*Liverpool*) writes, in reply to SPES MEA (see p. 542, No. 138), upon the cutting of pebbles:—"The apparatus is a lapidary's table, consisting of a small bench with raised sides. Under the table is a fly-wheel and treadle, and the wheel is geared on to another small wheel revolving on a shaft horizontally. The shaft passes through a hole in the table, and upon it small thin wheels of lead, sheet-iron, or wood, may be fixed for the cutting and polishing. The cutting is done by the edge of the wheel of sheet-iron, which is kept moistened with fine emery and water—the stone held against it by the hand or some mechanical contrivance. After the stone is cut, it is rubbed down on the face of a lead wheel with fine emery; it is then polished upon a wood wheel, using rotten-stone and water. The stone must be frequently looked at to see how it is getting on; all the scratches made by the emery must be rubbed out: the polish will appear after a time. Finish on a wood wheel covered with cloth or leather, using a little putty-powder. I think you might make the lapidary's table. All the other appliances may be bought at a paint-shop. The cost of a lapidary's bench, complete, means money. Do you think your few pebbles are worth it? I think your best plan would be to choose a flat face on the pebble, and to rub it down on a flat stone with emery, smooth with rotten-stone, and finish off on a piece of smooth slate with putty-powder and oil; finally, with putty-powder and oil on a piece of smooth glass."

**Drilling Grindstone.**—M. (*Bishop Auckland*) writes to T. A. D. (*Royton*) (see p. 510, No. 136):—"You might try a hollow drill in the form of a tube, fed by coarse sand and water. Unless the stones are very soft, you need not have any notches or teeth on the end of the tube. But why not have the holes made the right size at the quarry? In the Newcastle district the square holes are cut by a mallet and chisel; the grindstone is then mounted on a mandrel driven by steam, and the faces and edge turned with a steel tool. If you get the holes made 1½ in. square at the quarry, you can mount them in your machine as well as having a circular hole, unless you have some other reason for having a circular hole. To the best of my remembrance, the mandrels on which they are turned are circular, the stones being fixed by a plate and screw."

**Model Steam Launch.**—M. (*Bishop Auckland*) writes, in reply to A. M. C. (*Holywood*) (see p. 491, No. 135):—"If you refer to No. 71, Vol. II., of WORK, you will find a plan of steam launch. You can make it of yellow pine, free from knots or shakes, and hollow the inside out, leaving the sides ¼ in. thick. You can get engines from Mr. Lee, of Holborn, who advertises in WORK. If you will send me the size, I will tell you what size of engine you will require, and any other particulars you may require."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—S. (*Bristol*); A. M. L. (*Nuneaton*); F. W. C. ## MODERN WALL COVERINGS.

### SOME NOTES ON THEIR PRACTICAL AND DECORATIVE ATTRIBUTES.

BY FREDERICK PARSONS, F.S.Sc.

NEW AND OLD WALLS: HOW PREPARED—THE CLAIMS AND QUALITIES OF OIL PAINT, "TEMPERA," AND WALL PAPER—FLAT *v.* GLOSSY SURFACES—PAPERHANGINGS—LEATHER PAPERS AND DECORATIVE RELIEF MATERIALS.

"WHAT shall I do with the walls?" No question relating to the interior of the home comes to the scribe who deals with "Home Art" so often as the foregoing. To whiten the ceiling and carpet the floor are decisions "as a matter of course" to the average householder; but when it comes to the walls, he usually "hesitates and is lost"—or rather, his peace of mind often is. Doubtless, many readers of WORK have already found themselves in the above predicament. Many others will, in time, equally doubtless, be so situated. The capabilities of the "Shop" columns are almost illimitable in all directions excepting that of space; therefore, notwithstanding this momentous question of taste will continue to be asked through all time, it will fairly entitle the writer to the thanks of a patient and long-suffering editor, as well as the present generation of our readers, if we succeed in removing for a time so prolific a claimant for "Shop" space.

Although the ground we try to cover herein is of no slight dimensions, it must not be expected that the substance of folios can be condensed into a paragraph. The intention is rather to enable an inquirer to find within the limits of a brief paper, aided by the knowledge of his own individual circumstances of selection, a useful and correct answer to the opening sentence.

*New and Old Walls: How Prepared.*—In order to obtain the best results, a well made

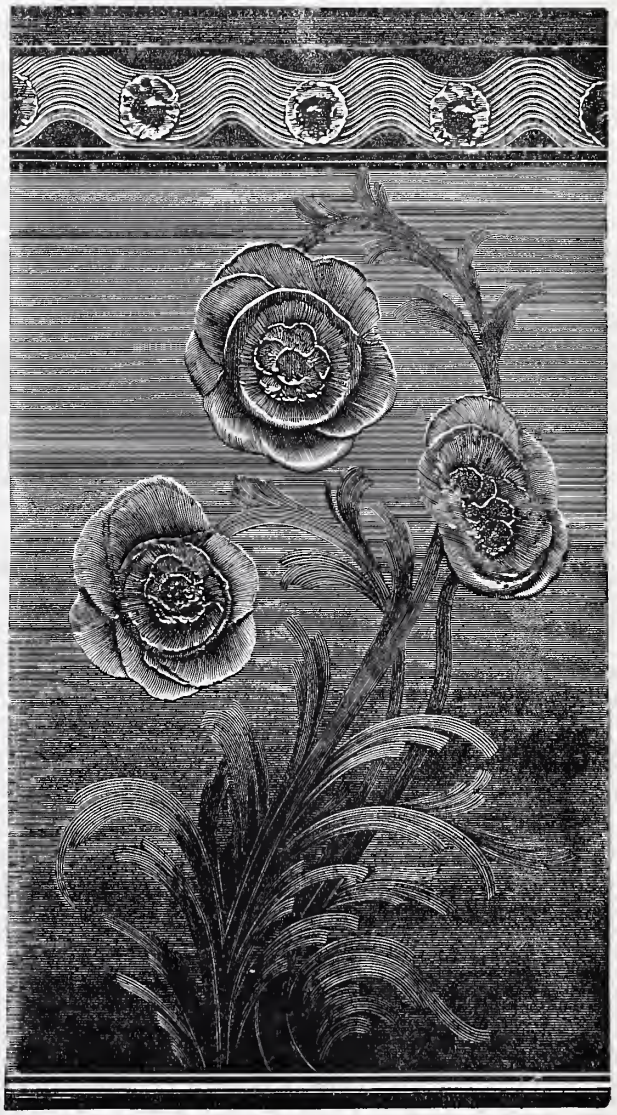

**Fig. 1.—Diaper for Walls (Ecclesiastical). Fig. 2.—Dado and Border: Semi-natural Treatment of Floral Motif (Domestic). Being Reproductions showing the Artistic Possibilities of Alabastine, the most Modern of successful Wall Coverings.**

and finished plaster surface is a *sine quâ non;* but, unfortunately, this is a condition of extreme rarity in the bulk of modern buildings of the cottage and villa type. However, we must make the best of that which we have. All old papers having been removed, and the old putrid paste and size well washed off the surface with warm water and a little soda or carbolic acid therein, we look to the plaster. If the surface skimming is cracked or blistered, cut it out; well wet the surface beneath, and make good to an even face with plaster and lime-putty, or plaster only if in small quantities. All holes and cracks being repaired, we rub down with glass-paper, and proceed according to the finish determined upon. If we adopt white lead and oil painting, see articles in WORK, Vol. I.; distemper or *tempera* processes are also explored therein. We therefore turn to the most favoured plan—wall papers. In fixing the latter, it is necessary to give ordinary plastered walls a preparatory coating of glue-size, diluted to a jelly consistency (when cold), and spread when warm. If this be not done, the moisture from the paste is at once absorbed into the plaster, making it difficult to fix the paper and to ensure proper and lasting cohesion between the two.

*The Rival Claims of Oil Paint, Distemper, or Paper* must be judged from various standpoints, some general to all circumstances, others particular to individual cases. Assuming that an ordinary plastered wall is under consideration, we state briefly the main practical attributes of the three treatments.

*Painted Walls* are somewhat costly, both for time in execution and for material; but, outside this, are certainly very serviceable, permanent, and sanitary, in the common acceptation of the term. With reasonable care, and having once been properly treated, a painted dining-room should last ten years, with careful washing every spring. It has one disadvantage: that in all but well-ventilated places any excess of moisture in the air condenses on the surface and trickles down the walls.

*Distemper*—in which term I include all water paints—is the antithesis of oil paint in many respects. It is not serviceable except in positions beyond reach and abrasion. It cannot be washed as can oil paint, and therefore permanence depends on position chiefly. Its chief qualities are cheapness, the temporary absorption and subsequent giving-off of atmospheric moisture, and the facility with which it can be completed.

*Wall Papers* to a certain extent combine the qualities of utility common to both paint and distemper. The main advantage of a pattern-paper lies in the fact of such giving a partly furnished sentiment to a room; whilst the pattern further prevents the eye noticing the knocks and soils that living-room walls are subject to. The cost of fixing a paper is about the value of distempering the walls; and since we live in an age of marvellously good and inexpensive papers, "you pay your money and take your choice" accordingly.

*Flat* v. *Shiny Surfaces.*—This is an aspect of the question directly connected with the previous treatments, which is well worth a little attention here. In oil-painted surfaces it is possible to finish the work in either a glossy or perfectly lustreless face—the latter appearance being technically known as "flat." The presence or absence of gloss thereon has much to do with the effect upon our mind of any painted wall. A flatted surface is obtained at some small sacrifice of durability; but where permanence is not the great object of using paint, a lustreless effect is infinitely preferable for the walls of all dwelling-rooms. By the judicious intermixing of linseed oil and turpentine, it is possible to vary the "shine" of paint to several definite degrees between the flat and oily extremes. The merits of the former are softness and repose to the eye, added to a full charm of *colour* employed; whilst the latter tries the eye by its reflection of light, destroys all feeling of softness, and mitigates against the effect of any tint employed. If flatted paint is cleaned by those who understand its nature, it is almost as durable as the oil coats; but when the average housemaid gets to work every spring with soft soap and the scrubbing-brush, nothing but the hard and glittering surfaces of oil paint, varnish, or enamel can long withstand these periodical onslaughts. We must, therefore, with respect to painting, choose between flatting and artistic effect on the one hand, and oil and durability on the other. Concerning distemper processes, little need be noted here, since a perfectly dead surface is one of the chief merits of water paints for use in the embellishment of interior walls. Where dados and such-like divisions of walls are permissible, paint may well be used for the lower part, and distemper for those portions out of danger of abrasion. Turning now to gloss on wall papers, we are confronted by a common practice of varnishing such—a practice against which we cannot speak too strongly. We may say at starting, that excepting such papers as imitation "oaks" and "tiles," for bath-rooms and butchers' shops, etc., not one paperhanging in ten can be varnished without great detriment to its appearance. Now, the main purpose of putting design on paper is certainly to increase the *artistic effect* of our homes; whilst, as before mentioned, the pattern prevents wear and tear from showing as quickly as on a plain-coloured surface. To varnish a paper with *copal* varnish (the usual plan) means to destroy the colour, and also all repose of the design. Staircase papers, with which we mainly are dealing, should invariably be cheerful and light in tone. If ordinary copal varnish is spread after twice sizing, as is necessary, upon any light paper, it gives it a nasty, shabby, "twenty-years-old" look; and although *spirit* paper varnishes are made which are almost colourless, they have not half the wear of copal, and, as is common to all, show every little inequality of paper and surface—a definite and lasting eyesore with badly plastered walls. The main and sole advantage of bright-varnishing walls is that they may be washed occasionally. It cannot, however, be too well known that copal varnish, even where washing is to take place, can be entirely dispensed with.

*Flatting, or Dead, Varnish,* although it will also *slightly* alter the colour of a paper, can be applied to such walls at a cost of a few more shillings than ordinary copal. We are of opinion, however, that no dwelling-house walls need be varnished at all. During the last few years sanitary washable papers—viz., papers printed in oil colours—have been greatly improved, and now possess sufficient durability even for staircases and bath-rooms. Not once in a hundred instances is a copal-varnished surface destroyed by fair wear; the householder gets tired and disgusted with it long before, and then the cost and trouble of removing it is an experience desired only once in a lifetime. The house-painter has been responsible for many common offences in his generation; but the worst, we think, must be the introduction and practice of varnishing wall papers.

*Paperhangings and Decorative Relief Materials.*—Having in the foregoing reviewed the practical *pros* and *cons* of my subject concerning wall coverings of comparatively an inexpensive nature, I will briefly notice the claims of the more costly products and materials. But first, a few useful notes on the varieties of ordinary wall papers. These may be divided into three classes, according to *quality, make,* and *surface.* The cheapest are known as "machine pulps," meaning papers in which the ground or pulp is itself coloured, and which are printed on afterward by machinery. They are retailed in prices from 2d. per piece of 12 yards run, to 1s., or even twice that sum, when sold with a good design upon them, and in tasteful colourings, as the speciality of a Regent Street firm. The next grade higher is known as "grounded papers" and "satins." The former term implies that the paper used, being white in the first instance, is grounded all over with the desired tint previous to the pattern being printed thereon. "Satins" are papers in which the ground or part of the design has been polished by the aid of powdered French chalk, etc., to a satin gloss. The value of the two last varieties is from 1s. to 2s. 6d. per piece. "Hand-printed" papers—viz., those having the design blocked on by hand instead of by machinery—are the most costly and artistic of paperhangings, ranging from 3s. to 10s. per piece. We have next the invaluable sanitary papers, made and sold in every range of colour and design, from 1s. to 3s. per piece. Embossed goods and imitation tapestry papers are the grounded and hand-printed kinds which are afterwards treated to a process of embossing, whereby varieties of texture effects are given to the surface, and softness to the colour and design is imparted. "Talc," "frosted," or damask papers are those of the best kinds, in which very silky effects are obtained by the use of powdered glass, etc. "Gold papers," so termed, are such as have parts of the design in gold bronze. If it were only possible to persuade the British public of their unsuitability for walls, the status of English home art would be greatly raised. Gold papers invariably give a flash and garish effect for a time, and then very soon the bronze turns black, and—instead of richness—shabbiness and gloom predominate. Gold papers are, happily, gradually going with "satins" into the list of things that *have been* popular. "Flock papers" are designs printed in flat relief of varying degrees of thickness. They are very expensive; but as it is usual to paint and flat them, a very soft and artistic surface of everlasting wear is obtained. Of leather papers and relief decorations, which are fixed like ordinary paperhangings, only with stronger mixtures of glue and paste, I must here say but little. The qualities of the former are those of the durability of paint, and with every range of artistic effect without the necessity of after-treatment. They range in value from 1s. 6d. to 10s. per yard super. Lincrusta Walton, Anaglypta, and similar well-known decorations, usually require after-painting; but both may now be purchased made in plain or elaborate colourings. Perhaps the most interesting recent addition to the formidable list of relief decorations is the "Alabastine," which has previously been brought to the

notice of our readers, and of which the two panel illustrations will speak volumes for its artistic possibilities and future. In a subsequent paper I will endeavour to further assist the reader respecting the mission of *colour* on our walls, with hints to its successful application.

## A TUNING METRONOME AND MONOCHORD FOR AMATEUR TUNERS AND MUSICAL INSTRUMENT BUILDERS.

BY H. CLARK.

*The Tuning Metronome.*—The simple apparatus to be described in this paper is intended for the assistance of amateur tuners and musical instrument builders, and was devised by the writer to enable him to tune, without professional assistance, a chamber organ which had come into his possession. It is not, however, in connection with *organ* tuning alone that this apparatus is useful, as it is equally useful in the tuning of the piano or harmonium.

The necessity for such an apparatus, and even its utility, may, perhaps, be questioned by professional tuners and qualified musicians, but it is confidently believed that such will not be the case with those who, whilst freely admitting the paucity of their musical acquirements, have still a love for the beautiful art, and are desirous of employing such talent as they possess in overcoming the difficulties which they may encounter in its pursuit. The apparatus has, however, received very favourable professional notice.

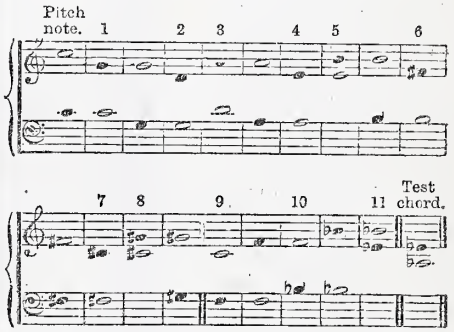
As most of the readers of this article will be aware, with the exception of the octave no musical interval, as rendered by fixed-toned instruments, like organs, harmoniums, and pianos of ordinary construction, is perfect, and it is usually the object of the tuner to so "temper" or distribute the imperfections of the various intervals as to allow of an approximately equal degree of softness and harmony being obtained in whatever key a piece may be played. This distribution of imperfections is termed tuning by "equal temperament."

If we take our place at the piano, and, selecting any note the strings of which are in unison, strike the key belonging to such note, and at the same time very gradually relax one of its strings by means of a tuning hammer, we shall observe a succession of "waves," or "beats," which, commencing slowly, will gradually increase in rapidity, until at length the result of our experiment is extreme discordance. If we strike any "third" or "fifth," a similar succession of slow waves will be noticed, and it is in regulating the rapidity of these waves, which varies as we ascend the scale, that our little apparatus comes into use.

The tuning metronome, shown in elevation in Figs. 1 and 2, consists essentially of a pendulum so suspended as to be readily adjustable to any required length, and is constructed as follows:—Two pieces of 1 in. deal board, 4 ft. long and 2 in. wide, are planed up true and square. At the distance of ½ in. from one edge of each piece a groove, ½ in. in width and depth, is made, as shown at *a*, in Fig. 3, after which the part *b* is planed away to the depth of ¼ in., as shown in Fig. 4. These two pieces are then screwed together with the grooves facing each other, as shown in Fig. 5, thus forming the standard. A strip of hard wood, such as beech or birch, 6 in. long, is then prepared, as shown in full-size section in Fig. 6. This will have to slide with as little play as possible, but without binding, in the T-groove formed in the standard. A flat bit of similar hard wood, 6 in. long, $1\frac{3}{4}$ in. wide, and ½ in. thick, is now to be screwed with a couple of screws to the tongue, *a*, of the slide, which should be left sufficiently high to prevent binding on the face of the standard. A piece of clock-spring, or hard rolled sheet brass, 6 in. long, is formed into a spring, as shown at Fig. 7, and fastened with screws through the straight part into the groove, *b* (Fig. 6), the curved part projecting somewhat beyond the face of the wood. At one end of the grooved face of the standard the wood must be cut away 3 in. long and 1 in. deep—*i.e.*, to the bottom of the T-groove—and a block of hard wood, $1\frac{1}{2}$ in. thick, fitted and screwed into the recess, leaving ½ in. projecting on the face to correspond with the slide described above. Two pieces of brass wire, $2\frac{1}{2}$ in. long and $\frac{3}{16}$ in. diameter, are now taken, and two holes, 1 in. apart and $\frac{1}{50}$ in. or less in diameter, drilled through each parallel to each other, one hole being ⅛ in. from one end of the wire. Two similar holes are drilled through a piece of similar wire, $1\frac{1}{4}$ in. long. The two longer pieces are to be slightly tapered at the undrilled ends. These pieces are then to be tightly driven into the face of the slide and the block at the top of the standard respectively, the holes being kept parallel to the length of the standard, and the inner one ⅛ in. from the wood when fully driven. The pin in the slide must be in the centre of its length, and that in the "head" 2 in. from the top. A pianoforte "wrest-pin" should be fitted into the head at 1 in. from the top and about ⅛ in. toward one side. This, likewise, is to be drilled with holes corresponding to those in the brass pins. A pendulum "bob" of about 4 lbs. weight, and preferably of lenticular form, must now be procured or made. The "bob" of an old "grandfather" clock, if available, will be just the thing. The short piece of drilled wire must be attached at the edge of the "bob," or to the regulating slide if the bob possesses one, the wire being kept parallel to the axis of the bob and at right angles to the slide, if any. A reference to the side elevation (Fig. 2) will clearly explain what is meant. Now lay the standard, face upward, on the work-bench, lay the bob upon it, with its centre not less than 36 in. from the pin in the head of the standard, and carefully mark the position of its top and bottom edges on the standard. These marks must be permanent. Find the centre between these two marks, and so place the slide that the lower side of the drilled brass pin in its face shall be exactly $7\frac{5}{8}$ in. from the centre mark just found, the distance being measured toward the top of the standard. Score across the face of the standard close to the upper edge of the slide and mark the line F—C[1]. Proceed in like manner to set off the following distances from the same starting-point, viz.:—$8\frac{9}{16}$, $9\frac{5}{8}$, $10\frac{3}{4}$, $12\frac{1}{16}$, $13\frac{1}{2}$, $15\frac{5}{16}$, $17\frac{3}{16}$, $19\frac{1}{8}$, $21\frac{1}{2}$, $24\frac{1}{4}$, $27\frac{3}{16}$, and $30\frac{3}{4}$ in., scoring across as before, and marking the lines E—B, E♭—B♭, D—A, C♯—G♯, C—G, $B_1$—F♯, B♭$_1$—$F_1$, $A_1$—E, G♯$_1$—E♭, $G_1$—D, F♯$_1$—C♯, and $F_1$—C. The pendulum bob has now to be suitably suspended. To do this, procure two pieces of hard wire of such a size as will just pass easily through the holes in the brass pins, and sufficiently long to reach from the pendulum bob to the wrest-pin in the head of the standard, with an inch or two to spare. These wires must be attached by soldering or otherwise to the cross wire of the pendulum bob, and threaded successively through the holes provided in the slide-pin, head-pin, and wrest-pin, which last must be twisted a few turns to retain the wires in their places. The foot for the standard is made of two pieces of 1 in. stuff, 18 in. long and 3 in. wide, the end of one being fitted to the centre of the other by a double tenon and mortise, as shown in the elevations, Figs. 1 and 2, and plan, Fig. 8. The standard is made to ride on the part A, Fig. 8, at *a*, where the thickness of A is reduced to ½ in., the solid wood at this part of the standard being removed to correspond. These parts should be well fitted, as a considerable strain is put on this joint when the apparatus is in use. Before use, the length of the pendulum must be so adjusted by means of the nut, *d*, immediately below the bob or by the wrest-pin, *e*, in the head, that the bob is truly centred in the position in which it was placed when the index scale was set out.

We have now a pendulum furnished with a flexible suspension, and so arranged that the touch of a finger will enable us to adjust it instantly as required to any length (and consequently to any speed) desirable. The lengths indicated by the index, commencing at the top and descending, correspond respectively to 11·3, 12·0, 12·7, 13·5, 14·3, 15·1, 16·0, 17·0, 18·0, 19·1, 20·2, 21·4, and 22·7 beats in ten seconds of time, and these rates correspond to the beats or waves heard when the fifths to which they respectively relate are properly tuned.

To use the instrument, middle C is first to be tuned with the assistance of a tuning-fork. We then proceed in the order indicated in the following scheme, in which the white notes indicate those already tuned and the black notes those to be tuned:—



The numbers at the top of the stave indicate the eleven fifths which are tuned successively by means of our apparatus, the test chord at the end being the remaining fifth of the circle. The unnumbered chords are octaves which it is needful to tune in order to keep our work within sufficiently narrow limits. Each octave is to be tuned "perfect"—*i.e.*, in exact concord—*and so left.* Each fifth must also be first tuned perfect, and the interval then diminished by *flattening* the *upper* note when tuning upward, as in intervals 1 to 8, and *sharpening* the *lower* note when tuning downward, as in intervals 9 to 11. The *amount* of flattening or sharpening is to be regulated by the metronome, which must be adjusted for each successive fifth by shifting the slide upward or downward as required until its upper edge lies exactly even with the line on the standard corresponding to the fifth upon which we are about to operate, and then setting the bob in motion. The note being tuned must be flattened or sharpened, as the case may be, *until the waves produced by the tempering exactly correspond with the beats of the pendulum,* when the note will be properly tempered. When the whole of the fifths 1 to 11

in the above scheme have been tuned in this manner, the result may be tested by trying the chord A♭$_1$—E♭, the separate notes of which have been obtained by working in contrary directions, thus making it a crucial test, which, however, our work should readily stand if proper care has been observed in respect of each step as it has been taken. Should it be found that the test chord is appreciably inferior to others the work must be carefully revised, an operation, by the way, which it is well to perform under any circumstances. Having tuned these notes, or, as it is technically termed, "laid the bearings," to our satisfaction, the remainder of our task is easy. We have only to tune the remaining notes on the instrument by octaves upward and downward from those already tuned. The correctness of this portion of our work may be tested by comparing each note in the treble with its *double* octave below, and each note in the bass with its double octave above, a proceeding which will most surely expose any error. The remedy for such an error is obvious.

*The Monochord.*—Thus far it has been assumed that the amateur tuner is directing his attention to an instrument which only requires the ordinary re-tuning operation, but as this paper is also intended to benefit the amateur instrument *builder*, it is necessary that we should "hark back," and suppose that our tuning operations have to be performed for the first time. In this case we shall derive great assistance from the use of a *monochord*, a simple instrument having, as its name implies, only one string, which string, however, is so arranged as to be capable of being "stopped" in such a manner as to produce successively all the semitones between the note to which its entire length is tuned and the octave to that note, the foundation note itself being obtained by means to be described.

The monochord, illustrated without string in Fig. 9, is constructed as follows:—The baseboard, *a*, is a piece of pine 2 ft. 6 in. long, 4½ in. wide, and ¾ in. thick, rounded at the upper end, at 3 in. from which a 1 in. hole, *b*, is drilled as a means by which it may be suspended when in use. At 6 in. from the top this board is crossed at right angles by a "bridge" of hard wood, *d*, 1 in. deep and ½ in. wide at the base, the top edge being reduced to barely ⅛ in. in width, and afterward shaped somewhat as shown in the Fig., leaving only about 1 in. in the centre of full depth. This bridge may be attached by means of a couple of screws passed through the baseboard from behind, and will be all the better for having a flat-topped wire staple driven into the centre of its top edge to assist in sustaining the pressure which will be brought to bear upon it. The following distances must be carefully set off from the centre of the fixed bridge along the centre of the baseboard, viz., 10, $10\frac{1}{16}$, $11\frac{1}{41}$, $11\frac{15}{16}$, $12\frac{1}{16}$, $13\frac{5}{16}$, $14\frac{3}{16}$, 15, 16, $16\frac{7}{8}$, $17\frac{13}{16}$, $18\frac{15}{16}$, and 20 in. respectively, and corresponding lines scored across the baseboard at right angles to its length by means of a joiner's square. The best way to set out these distances is by resting one edge of a set square on the baseboard as indicated by the dotted lines in the figure, and then taking the measurements from the top of the bridge to a point 1 in. from the right angle of the square. A mark made on the baseboard at this angle will be at the correct distance. The lines so set out are to be marked at one or both ends, C♮, B, B♭, A, G♯, G, F♯, F, E, E♭, D, C♯, and mid. C respectively. We now insert a small screw-eye at *c*, and are ready to string our instrument. To do this we take a piece of small-size piano wire—about No. 24 B.W.G. will be found suitable—*very carefully measure off 38¾ in., and ascertain its weight in grains.* For example, taking a piece of wire about 4 ft. long, we stretch it tightly between two wrest-pins or screws inserted in a plank and carefully measure and mark off the required length, which we then cut off as accurately as possible at the marks made, and ascertain its weight. Suppose this to be 31·7 grains. *This is the weight in pounds avoirdupois by which the string of our monochord must be stretched to cause it to produce the sound mid. C when vibrating at its full length of* 20 *in.* We now twist a small open loop at each end of the wire, which we then attach by one end to the eye, *c*, at the upper end of the baseboard, which must be suspended to some convenient nail by the hole provided for the purpose, and to the other end suspend the necessary weight, 31·7 lbs., equal to 31 lbs. 11¼ oz. nearly. If we now take an ordinary violin bridge and insert it between the baseboard and the string at the mark mid. C, we shall find that the string, on being twitched by the finger, will yield the note mid. C, or a very close approximation thereto. The note is to be corrected, if needful, by comparing it with a C tuning-fork and *gradually adding to or subtracting from the stretching weight according as the tone is found* to be flat or sharp, until perfect concordance is arrived at, when our monochord will be complete.

We may now commence operations on our hitherto untuned instrument. We begin by tuning its middle C to accord with the monochord, and follow on by tuning C♯, D, E♭, and so on until we have completed the octave, the movable bridge of the monochord being adjusted as required. Having one octave tuned in this manner, we tune downward therefrom to the F in the octave below and then bring our tuning metronome into use as before described.

## HOW TO MAKE A DOOR.

BY E. D.

This short paper is to be taken as a practical reply to a question too long for "Shop," embracing the making of a door, put by Cowl (*Belport*).

Figs. 1, 2, and 3 show the front elevation, vertical and horizontal sections, of a four-panelled door. The horizontal bars are called the top, middle, and bottom rails respectively; the vertical pieces the stiles

(hanging and lock); the centre-pieces the muntings, or mullions; the panels top and bottom, as the case may be.

Fig. 4 shows the various pieces, with their names, showing how the door appears when it is all ready to go together. The mouldings are left out, for the sake of clearness.

Fig. 5 shows the door partly put together, with the panels omitted.

The method of procedure is as follows:—

First cut off and joint your panels to the width required (that is, if they are more than 11 in. wide, for up to this width you can buy stuff without any very great extra expense, but after 11 in. wide stuff gets very expensive). The joint in panels should

The pieces are now ready for setting out. The way to do this is to first put your two stiles together, face to face, with the tried-up marks inside and upwards; square across both edges about 2 in. up from the bottom, the width of your bottom rail; now from the bottom of the bottom rail measure off the height of your door, and square off the width of your top rail, working downwards. Find the centre of the height of door, and 1 in. above the centre square across the top of the middle rail and the width, working downwards. The inside of the top and bottom rails, and both sides of the middle rail, having to be ploughed for the panels, ½ in. deep, it is quite evident that the tenons

as long as the plough groove is deep. This is termed the haunching. Now allow ½ in. above and below all the marks you have made for your mortises for the wedges, turn your two stiles down, still keeping them together, and square the mortises round to the opposite edges. The marks for the wedges are generally only put on the outside edges of the stiles, as they are not necessary on the inside edges—in fact, are apt to be very confusing.

Now lay your mullions on the stiles, and square them round to the distances between the top and middle and middle and bottom rails: not between the tenons, mind. This will give the cutting line for the shoulders. Now

**Fig. 1.—Four-Panelled Door: Front Elevation. Fig. 2.—Ditto: Vertical Section. Fig. 3.—Horizontal Section. Fig. 4.—Various Pieces of Door, except the Mouldings—A, A, Top Panels; B, B, Bottom Panels; C, Top Rail; D, Bottom Rail; E, Middle Rail; G, G, Stiles; H, Shoulder; W, Wedge. Fig. 5.—Door partly put together, with Panels omitted.**

be what is known as tongued and grooved. Now rip out the stuff for the stiles. These are generally what is termed 4½ in. wide—that is, a 9 in. board cut down the centre. The top rail should be the same width as the stiles; the middle and bottom rails should be 9 in. wide. The stiles and rails must now be planed very straight, and out of winding on one face, and one edge shot perfectly straight and square with this face. If possible, try and arrange that this tried-up edge works with the grain, so that when you plough for the panels you do not have to work against the grain. Put a tried-up mark on the planed face and edge. (See p. 696, Vol. I.) Next gauge your various pieces to as wide a width as the stuff will hold up, and thin or gauge to a general thickness.

on those edges of the rails will be ploughed out, so set up and down, as the case may be, ½ in. on the edge of stiles—this will give you the inside edges of the mortises. Next set down, 1½ in. from the top of top rail, and 1½ in. up from the bottom of the bottom rail, and this will give the width of all your tenons; but as the bottom and middle rails are so wide that to make a mortise as wide would greatly diminish the strength of the stiles, there is generally two tenons, formed as shown. (See Fig. 4.) In good work there are always four tenons on the end of the middle rail that take the lock, so that the lock passes between the tenons, and does not weaken the door so much. A piece is left between the tenons of the middle and bottom rails and above the tenon of the top rail, and below the tenon of the bottom rail,

take your rails: lay the bottom one on the bench face upwards, on top of this the middle rail face upwards, and then the top rail face downwards, keeping the tried-up edges towards you. Square down the distance between stiles and the width of mullion in centre, allowing the mortise for the mullions ½ in. less on each edge for the plough groove. Take the middle rail out, and square over to the opposite edge for the mortise for the top of bottom mullion; square over the shoulders of the rails of both sides, and then with a mortise gauge, set to the thickness of the panels, which should be just under the third of the thickness of the framing, but of such a thickness that will suit your plough iron and mortise chisel.

Now cut the tenons, make the mortises, and plough for the panels, taking care that

all your gauging and ploughing are done from the tried-up or face side. After ploughing the stiles and rails, plough a groove in the same manner across the end-way of a piece of stuff, about 4 in. long, 2 in. wide, and the same thickness as the stiles. This is called a mullet, and is used for gauging the thickness of panels.

The framing should now be knocked together, and see that all the shoulders are up. By doing this, you know that if the shoulders do not come up when you get the panels in, the fault is in the panels, and not the framing. Now having got the door together, you can easily get the exact height and width of your panels, which should be now cut off to the exact size, allowing them a trifle narrower and shorter, so that they do not stop the framing from coming together all right. Plane up one side of the panels, and then try to get the grooved mullet on the edge all round, reducing them until you can do so. You may then be sure that the panels will go into the grooves in your stiles and rails quite right, because a similar groove has been all round them. Knock off the stiles, put in the panels, cramp the door together, to see that everything is as it should be, prepare your wedges, and you are ready for gluing up.

The method of gluing up a door is to lay two pieces across the bench as long as the width of the door. See that they lay out of winding, and are just a little above the bottom rail and below the top rail, so as not to interfere with the cramp. Take the door to pieces, glue the mullions into the rails, taking care that no glue gets into the panel grooves, put in the panels, and knock the stiles on as quickly as possible, but not quite home. Now glue as much of the tenons as is left exposed between the shoulders, and cramp up; drive the wedges of the middle rail first, then the bottom, and lastly the top rail, wedging the bottom rail upwards on to the bottom mullion, and the top rail down on to the top mullion. Now set the door on one side, to allow the glue to dry. When the glue is dry, take the two pieces off the bench, lay the door flat down, and cut a piece of wood thinner than the door, tightly between the horns, above and below the top and bottom rails; nail these pieces to the bench, and they will hold the door firmly whilst you clean it off and put in the mouldings.

In bradding in the mouldings, care should be taken that you do not nail into the panels, but into the framing, for if you fasten the moulding to the panels they cannot shrink (not that they ought to), and so split up the middle, or wherever they are jointed. After this is done the door is completed, with the exception of cutting off the projecting ends of wedges and the horns; but the horns are generally left on to protect the rails, etc., until the door is fitted into its place.

In giving this description of making a door, I have assumed that you are conversant with the method of making the mortises, cutting tenons, and planing up stuff, or you would never attempt to make a thing that could be bought for the same money as you could buy the materials, if bought in small quantities, allowing for waste, etc. But if you only want to make it for the pleasure of doing so, I should advise you to first thoroughly digest the above, and then buy an old door for about a shilling; cut it right across the lines marked *a a* and *b b* in Fig. 1, and this will give you a practical demonstration of the horizontal and vertical sections.

## CONSTRUCTIVE STRENGTH IN METAL WORK.

BY J. WHITFIELD HARLAND.

HYPOTHESES CHALLENGED—SIR WM. FAIRBAIRN AND HODGKINSON—TAY BRIDGE—SIR JOHN FOWLER'S CONDEMNATION OF RAILWAY BRIDGES—NEUTRAL AXIS NOT ALWAYS, IF EVER, CENTRAL—SUGGESTED EXPERIMENTS—WROUGHT IRON PREFERABLE TO CAST—USE OF STEEL TO SUPERSEDE THAT OF WROUGHT IRON—REITERATED TRANSITORY LOADS—CONTRACTION AND EXPANSION—BOX-GIRDERS: THEIR COMPARATIVE STRENGTH—DISHING OR CORRUGATING PLATES—DOUBLE BOX-GIRDER BRIDGE—DRILLING RIVET HOLES PREFERABLE TO PUNCHING—TANKS: THEIR SHAPE, CAPACITY, WEIGHT OF CONTENTS—STAYS—CROSS-STAYS—BEARERS FOR—CONCLUSION.

I HAVE endeavoured to show in former papers how to counteract forces known to be in imperceptible action in all constructions tending to destroy them, either by carrying them off harmlessly or by pitting one against the other, and thus neutralising them; but a few important items yet remain that seem to me worth reasoning out in the same connection.

My former hypotheses on one or two points have been pointed out by correspondents (see "Shop," p. 363, Vol. III.) to be open to the charge of being contrary to the leading engineers' teaching of to-day. I would say that I do not write by any means as an authority, but suggest the probability of error in practice. Until the experiments of Hodgkinson and Sir Wm. Fairbairn, the proportions of the upper flange of a girder to the lower flange were not understood *by the then authorities* to have any ratio to the difference between the resistance of cast iron to compressive and to tensile strains; so much so that Sir Wm. Fairbairn, in his "Application of Cast and Wrought Iron for Building Purposes," states that "very commonly girders were laid indiscriminately either side up," it not being thought that it made any difference! Is it not, therefore, possible that there is still something unknown to present authorities?

That there is, and has been, bad construction, two instances will be sufficient to prove. Sir Wm. Fairbairn showed the weakness of the Tay Bridge so long ago as 1864, if not earlier; and now, on one railway alone, Sir John Fowler has condemned *nearly half the bridges* as dangerous.

I further pointed out that a great responsibility rests on those who construct bridges and buildings, where failure means often a sacrifice of life and limb, and I consider it is their duty to find out by actual experiment the value of any suggestion thrown out. I repeat that I think the centre of the web is the most fatal position for holes (by centre, I mean equidistant between upper and lower flanges).

One correspondent quotes Sir John Anderson: "Holes may be made with impunity in the neutral line." I have not referred to the book to see whether this is in reference to *cast* girders, but supposing that it is so, still this does not absolutely contradict my theory, although it appears to do so, because the neutral axis is not always—if it ever is—equidistant between the flanges. Is it not probable that holes *alter* the neutral axis? I will not here repeat my reasons, already given, for holding this opinion, but suggest that model cast-iron girders (for I limited the remarks solely to cast girders) on a small scale, all off one pattern, could easily be made and subjected to pressure till broken, after the holes had been made in different positions in each; the breaking weight in each case would show the value. In like manner, holes in the upper flange of same diameter, in similar positions relatively to the length between supports, being made, such diameter to be, say, equal to thickness of the web, and the breaking weights being ascertained, would give the value for comparison. It is, of course, quite possible that these experiments have already been made; but if so, I have not seen the results. It is true that in modern times the tendency is to substitute wrought iron for cast, because, strength for strength, the former is both lighter and more economical in the long run, and because its elasticity and flexibility are nine or ten times as great, and also from the fact that a warning is given of its fracture by gradually giving way, which the latter does not, so that the value of the above experiments would be much dwarfed. As steel becomes more cheaply obtainable, we may expect that it, in turn, will supersede wrought iron in building construction, it being lighter, strength for strength, still more flexible—and therefore, after deflection by transitory loads, leaving less permanent deflection or *set*—and more fibrous.

It has been established that not only time itself, but the constant application of transitory loads and their removal, in addition to permanent loads, upon all girders, ever reiterated, must in the end result in destruction; but so far it has not been sufficiently subjected to research and experiment. Just as we know that "constant dripping wears away stone," so we know that trains passing over a bridge time after time will ultimately undermine its constitution, and result in its ultimate destruction. We do not know, as yet, the true antidote to administer for deterioration. Therefore, we use more material and increase the strength of construction to a probably safe proportion of three, four, or even six times the greatest possible strain before the calculated breaking strain can be reached. Science will, no doubt, ultimately furnish us with the means of overcoming this tendency to deterioration; at present we ought to be thankful that we know of its existence.

I must disagree with a correspondent who says that in bridges of 40 ft. to 50 ft. span no allowance for expansion and contraction is made—which may be the case—as to its being unnecessary. If the expansion only amounted to ½ in., something would have to give way. However slight the extent might be, still the strain would be there; and in the event of the bridge having been deflected permanently, there would be a tendency to increase still more such deflection. I think I remember being told whilst walking over the top of one of the tubes of the Menai Tubular Bridge that its expansion, in all, had in some cases exceeded 1 ft. in its length. Every schoolboy knows that this was foreseen and provided for.

In my former papers I omitted to mention the so-called box-girder, which consists of the longest possible strips of wrought-iron plate riveted to angle-iron at their edges, to form a square, or, rather, oblong tube, instead of a central web and two flanges. The box-girder has, therefore, two webs, one at each edge of the flanges. Sir Wm. Fairbairn gives the proportionate strength, other things being equal, of the box-girder at 100, the plate-girder (one web) at 93, and the trellis-girder (not the lattice-girder) at 84. It has, however, one drawback—viz., that its interior cannot be re-painted from time to time; but this

might be remedied by the plates being made rustless by the Bower-Barff process at but slight expense, when neither inside nor outside would require painting at all. Certainly, the tendency to buckle must be less in them than in other (single-web) girders. The longer the strips the fewer joints across there would need to be: hence, if possible, the whole of the girder should consist of but one long strip from end to end for each side, for top and for bottom; and if joints are required, the plates should lap over sufficiently for eight or ten rivets in line (chain-riveting, as it is termed), lengthwise.

Of course, a box-girder should be laid, not on its side or widest dimension, but on its narrowest; the deeper it is, within certain limits, the stronger it will be. I am inclined to think that it would be strengthened yet more by fixing inside it crosswise plates fitting its hollow at intervals, and still more by dishing or corrugating the long strips of which its sides are constructed, which would stiffen it still more. This would also tend to take out of the plate the inherent buckle that seems to occur in almost all rolled plates: due, no doubt, to unequal contraction in cooling. The top and bottom might also be corrugated, but lengthwise—not as in the case of the sides, across or merely bellied out to form a slight arch. Whether the extra cost of thus adding to strength and stiffness would or would not discount its advantages is another matter.

For a bridge, it occurs to me that with two girders of the box type, the upper one straight and the lower one arched to a segment of a circle, and so fixed that it should abut on springers at the pier, and, rising, meet the underside, and support at the centre the straight upper girder, good construction would result, and the spandrels thus left might be strutted with radial diagonals or otherwise, or might even be filled up with dished or corrugated plates riveted to angle-iron first riveted to the centre of underside of top and upper side of lower girders. In all riveting operations I should prefer drilled holes to punched ones, firstly, because there is less disturbance of the iron fibres, just as a clean cut is better than a bad bruise; and secondly, because it is easier to set them exactly opposite the corresponding holes in the angle-iron or the other plate, and thus greater accuracy is secured: and as many holes can be drilled simultaneously, the cost of the work can hardly be greater.

In conclusion, I should like to put in a word or two about cisterns and tanks: not that they demand any great amount of science in construction, but because they are, for that very reason, more likely to be attempted by amateurs; and some remarks on them may be appreciated by WORK readers.

Tanks made of galvanised iron, as it is termed, are not really made of this material, but of ordinary iron riveted to angle-iron at the corners and round the open top, and when finished are "galvanised" by being dipped whilst hot in melted zinc—a process which most makers, and, therefore, all amateurs should, delegate to those who make this their business.

The shape of the tank must often be governed by the space at one's disposal: it may be square cubically, or long, narrow, and deep, or long, broad, and shallow, etc., and still hold the same quantity of water. To find its capacity in gallons, multiply its length and breadth together, and then this by its depth, and the total in cubic feet by $6\frac{1}{4}$. Thus, a tank 3 ft. long × 2 ft. wide = 6 square ft. × 1 ft. deep = 6 cubic ft × $6\frac{1}{4}$ (gallons in a cubic foot) = $37\frac{1}{2}$ gallons. To ascertain weight of water, multiply number of cubic feet by 1,000 (ounces in a cube foot) and bring it to lbs.; thus, in this case, $\frac{6000}{16}$ oz. = 375 lbs. when full.

In cisterns or tanks of greater length than 4 ft., unless of very thick plate, a stay should be riveted across to prevent the sides bulging out; when they are also more than 3 ft. deep, another stay, halfway up, should be riveted across, and if the width be over 4 ft., a cross-stay will be necessary; two if it be also deep. Its total weight plus weight of water when full should be ascertained, so as to guard against the bearers on which it rests being too weak to carry it. As it is not a permanent load, but varies as it empties and fills, the bearers ought to be able to bear at least four times its maximum weight.

Such tanks are far preferable to wooden ones lined with sheet zinc, are far less liable to deteriorate, and could readily be made by an amateur, especially if he had a good drilling machine. Do not use copper rivets, but red-hot iron ones; otherwise, should any portion of the galvanising be imperfect, magnetic action would be set up between the copper and the zinc, and the tank would soon leak in consequence. This concludes the *causerie*—for it cannot be called much more—on Constructive Strength in Metal Work, which subject is far too vast for more than mere passing notice of a most superficial character, intended only to show what to expect and what to investigate, and what experiments to try before any important construction is attempted.

## SUB-STAGE AND POLARISCOPE FOR MICROSCOPE.

BY H. B. STOCKS.

SUB-STAGE—UTILITY OF POLARISCOPE—METHOD OF MAKING SUB-STAGE—STANDARD SIZE OF SUB-STAGE—METHOD OF MAKING POLARISCOPE—FITTING OF POLARISCOPE PROPER—OF ANALYSER—PRISMS USED—METHOD OF FIXING SUB-STAGE TO MICROSCOPE—CENTREING.

To those readers of WORK who have a microscope, the adjunct which I am about to describe will no doubt be valuable, as it consists not only of a polariscope, but also of a sub-stage into which many other accessories may be fitted in place of the polariscope, and also when using the apparatus they may be thrown in or out without disconnecting them, which has usually to be done.

The polariscope is a useful adjunct to the microscope for the examination of starches, and also rock and mineral sections, and the price is about £1 4s. for polariser and analyser. As I had a microscope without a polariscope, it occurred to me that one might be made for much less than that sum, and the following is a description of how I made it. Those who have a lathe will find no difficulty in the making, but as I had no lathe I had to get the turning done for me.

Fig. 1 shows a general view of microscope with polariscope fitted, and Fig. 2 underside of stage, showing the two positions of sub-stage. The fitting consists of four portions: (1) The sub-stage; (2) the fitting for polariscope; (3) the polariscope; and (4) the analyser.

(1) The sub-stage consists of a casting of a ring, having a projecting portion upon it of about $\frac{1}{8}$ in. thick. The ring, when turned, is $\frac{3}{4}$ in. deep, and must be perfectly true on the face, and turned inside to such a size that a ring $1\frac{1}{8}$ in. external diameter will slide within it, but will not slip out: what may be called a full $1\frac{1}{2}$ in.; the outside of the ring may be turned down to about $\frac{1}{4}$ in. thick to reduce the weight, leaving the upper portion, the width of the projecting piece, a little thicker. The projecting portion is for fixing to underside of stage of microscope, and will require filing into shape (Figs. 2 and 3).

The sub-stage, being of the standard size, will take any other fitting made of the standard size—*i.e.*, $1\frac{1}{2}$ in., which is the usual one.

(2) Fitting for polariscope.—A piece of tubing is now required $1\frac{1}{2}$ in. external diameter and $\frac{3}{4}$ in. wide; this can be bought. If it is a trifle over $1\frac{1}{2}$ in., turn it down to the proper size. Now cut out a circle of

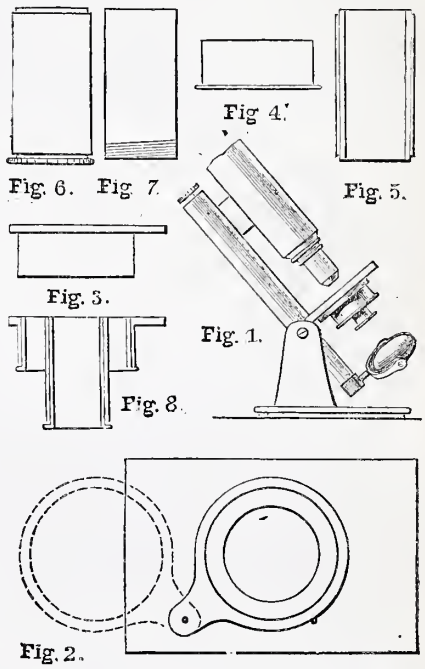

**Fig. 1.—Microscope with Polariscope fitted. Fig. 2.—Underside of Stage, showing Two Positions of Sub-stage. Fig. 3.—Sub-stage. Fig. 4.—Ring and Circular Plate. Fig. 5.—Tubes of Polariscope. Fig. 6.—Polariscope Tube finished. Fig. 7.—Analyser. Fig. 8.—Polariscope and Ring combined.**

sheet brass $1\frac{3}{4}$ in. diameter, and exactly in the centre bore a hole $\frac{3}{4}$ in. in diameter; this will require enlarging slightly to take polariscope. Braze or solder the circle to the ring (Fig. 4).

(3) The polariscope consists of two pieces of tubing, one of which will slide easily within the other; the inner tube is $\frac{3}{4}$ in. external diameter and $1\frac{1}{4}$ in. long., and as it will be found difficult to get a tube to fit over this, a piece of tubing may be taken $\frac{7}{8}$ in. external diameter and 1 in. long. Cut it open lengthways by means of a fret saw, file a little off each face of slit, and solder or braze together again. It will now be a trifle too small; the smaller tube may be turned down outside until they fit (Fig. 5).

Another portion of the larger tube may be treated in the same way and cut into two rings, each $\frac{1}{8}$ in. wide. Braze or solder one of them on to one end of small tube; on the other ring, inside, get a thread turned, and a corresponding male thread on the other end of small tube. Now cut out a

circle in sheet brass 1 in. diameter, and in the centre drill a hole ⅝ in. diameter; solder or braze this circle on to the ring with thread cut upon it, and it will then form a kind of cap, screwing on to the smaller tube. Place the larger tube on to the smaller one, and then screw on the cap. When screwed up tight it should allow the outer tube to move round easily; a drop of oil will help it to do this.

The polariscope tube is now finished (Fig. 6). Solder or braze it into the hole which you have made for it in the 1½ in. ring, having the top of the polariscope flush with the top of the ring, and the screw cap outside (Fig. 8).

(4) The analyser.—Fig. 7 is a plain piece of tube similar to the smaller tube of polariser, with a thread cut on one end to fit thread which is usually cut inside of objective, and it is screwed into the objective before screwing it on to the tube of the microscope, and of course goes inside the tube. If there is no thread inside the objective, then some other method of fixing must be devised; even placing on top of objective will do.

The two prisms of Iceland spar had better be bought; I do not advise anyone to try to cut and polish and cement them, as it is a difficult thing to do. Send inside diameter of small tube of polariscope to any microscope maker, and I have no doubt he will supply them. They are fixed in the tubes by cutting a cork in two, cutting out the centre of the shape of the prism, and putting the whole thing, cork and prism, into the tube, taking care that the prism is exactly in the centre of the tube; if a thin glass circle is cemented on to each end of the corks, it will prevent dust and moisture getting to the prisms.

The difficulty now will be the fixing of the sub-stage to the stage of the microscope. Drill a small hole in projecting portion of sub-stage for screw to pass through; glue to the upper face of the sub-stage a sheet of paper, and make a small hole directly in the centre of the ring (this can be done with compasses). Fasten the sub-stage to the underside of stage by means of clamps somewhere about the right position, and having a moderately strong objective, look for the pinhole in the paper, move sub-stage until it comes into view, and bring it directly in the centre of the field; you will be surprised to see the pinhole, as it will look more like the crater of a volcano than a pinhole. But, however, proceed. Having got the pinhole right in the centre of the field, with a steel point placed in the hole in projecting portion of sub-stage, make a mark on the stage, and bore your hole there, not quite through; tap it (small taps are sold at 6d. and screws at 6d. per dozen, very suitable for this kind of work), and having filed the screw to the proper length, screw on the sub-stage. Also fix a peg for it to rest against when in proper position (Fig. 2).

It is important that the sub-stage be properly centred, otherwise on revolving the polariscope the field of view does not appear properly dark and light, which is essential for good work.

For the properties of polarised light see WORK, page 389, September 7, 1890; and the lacquering has already been described in "Shop," so there is no necessity for me to say any more on this part of my subject here. To save readers the trouble of asking where the instructions have been given, let me suggest a search in the index to each volume, which every amateur workman and reader of WORK should possess and use.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

SETTING OUT, INVOLVING THE USE OF THE SQUARE AND GAUGES.

We have dealt with the plane and saw, only using the square to test the accuracy of our planing, or to make guide lines for sawing. This naturally leads on to "setting out," in which judgment is required. First, as to the joinings required. In order to make, say, a table top, the use of the plane is required, as has been described. There are several lessons on the subject in Vol. I., to which refereuce should be made. Such joints are to add to the width of wood, or to allow it to be made into articles for which one width of stuff is not sufficient. Then there are a multitude of joinings to unite pieces at right angles to each other; of these, the dovetail and the mortise and tenon are, perhaps, the most important, though other joints are of constant occurrence. When two pieces, say, 6 in. wide and 1½ in. thick, are to be joined at right angles, if the joint is in the width, or the 6 in. of each united, then dovetails are usually suitable; if the edges, or the 1½ in. surfaces, are to be joined at right angles, the mortise and tenon will be, no doubt, more eligible, but much depends on the direction of the grain, as tenons are only suitable when at the end of a rail, and mortises are only available when chisel cuts at right angles to fibre of wood.

If mortise and tenon are chosen, appearance and custom suggest that the mortises should be cut in the vertical pieces, or stiles, as they are usually called; this implies a vertical joint, and that the vertical portion of the frame is continued to the base. An illustration may be found in doors and shutters. If the wood is joined like the sides of a box, probably dovetails will be more suitable.

In either case the use of the square and gauge must be acquired. We will first look at the tenon. This is formed by cutting away part of the wood at each side. Generally, but not always, the surfaces of the tenon are parallel with the surface of the wood; a gauge is therefore a proper instrument to mark the lines to guide the sawing of the tenon. As the tenon is of uniform thickness, a gauge with double teeth may be used; this is called a mortise gauge. The mortise gauge is set so that the distance between the two points is equal to width of chisel used to make the mortise.

The mortise also is usually parallel with the surface of the work, so this gauge, which might with equal truth be called a tenon gauge, is applicable to both purposes.

The proportions of mortise to the work are not very definitely fixed, but custom has fixed the width of the mortise at about one-third of the thickness of ordinary work, or a trifle more. rather than less. As suitable chisels are made for mortising to every $\frac{1}{16}$ in., between useful limits, we can easily find one suitable for any purpose or thickness of wood. The width of the tenon is generally about two-thirds of the width of rail, but in some cases, internal rails for instance, they are often the full width of the wood. Tenons that are too wide, however, are apt to become loose through shrinking. In wide rails, therefore, two or more narrow tenons are preferable to one wide one.

In order to ensure correctness and good work, the rule, square, and gauge cannot be used too much.

## STAGE CARPENTRY.

BY WILLIAM CORBOULD.

PRACTICAL DOORS AND WINDOWS—MODE OF MAKING DOORS AND WINDOWS—SPRINGS, DOGS, ETC.—VAMPIRES—HINGES FOR VAMPIRES.

*Practical Doors and Windows.*—In scene painting, doors and wiudows are, of course, frequently painted, but it is of those which are used in a practical manner that I wish to treat here. These are generally made in cottage set pieces or in flats. I must here explain. A cottage set piece is usually set from one of the wings, as shown in Fig. 14. Flats, on the contrary, are two built pieces seut on from each side of the stage, meeting in the middle, and buttoned or hooked together, forming one flat surface, similar to a cloth when rolled down. At the same time a flat may be drawn up where there is room to do so, but then it would be made in one instead of two parts. We will suppose that a cottage is either on the right or left side of the stage, usually called the P. and O. P. sides—that is, "prompt" side and "opposite prompt."

*Mode of Making Doors and Windows.*—The door or window of a cottage is made with the same framework as the set piece, covered with canvas the same. When making it leave a good ½ in. all round, so that it may work easily. Use back-flap hinges: those about 1½ in. or 2 in. will be found to be strong enough. There should be an india-rubber spring on the front of the door at the top corner, so as to ensure its closing after passing through, as there may be scenery on the other side, or inside of the cottage, which would not be appropriate if the door should not close. The cottage might be standing in front of a foliage or rock scene, instead of showing the inside of a cottage. Therefore, as soon as the person has passed through the door should close. By the same rule windows should do the same.

*Springs, Dogs, etc.*—In Fig. 14, D is the wing, C the cottage, B the sky border. The spring is seen fixed at A. These springs are bought at about 7d. each. They are shown in Fig. 15. A shows the spring; the rubber is bound round two brass eyelet holes; one end is fixed on the doorpost with the screw, B, the other end is caught by the hook, C, fixed on to the door, as at D. Cottages or set pieces are usually held in their place firmly by the use of dogs. There are several ways of making these; the most simple one is dog No. 1, which is shown in Fig. 16. Dog No. 2 has a twisted half screw at one end, and the dog, when being fixed, is held on one side, the twist being put into the eye and the other end brought down to the stage and fixed with a stage screw, B. Dog No. 3 would be fixed with two small stage screws or screw-eyes, one to the set piece and the other to the stage. Sometimes a staple or screw-eye is put into a wall or post, one in the set piece, which may be held by a dog, as shown in Fig. 17. Another good way of fastening, which I invariably adopt when possible, is to tie with a piece of cord. Have a screw-eye in the set piece with a piece of good cord, such as small sash-cord or Venetian blind cord: keep this on the set piece so that it is always ready when placing it in position. Have another screw-eye in the wing, or whatever the piece may be set against; slip the cord in, and make fast by a good slip-knot. This method of tying is much safer than hooks and eyes, as these often come undone, which should be avoided: all fixings should be made as safe as possible, rendering accidents almost impossible.

*Vampires.*—We now come to the making

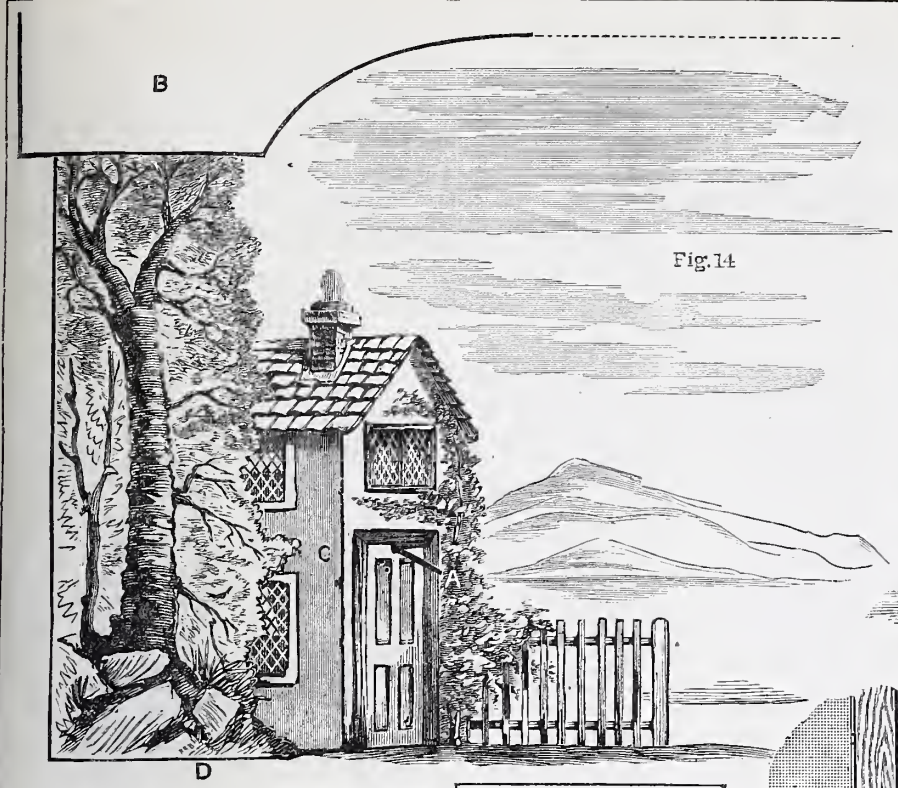

Fig. 14.

Fig. 17

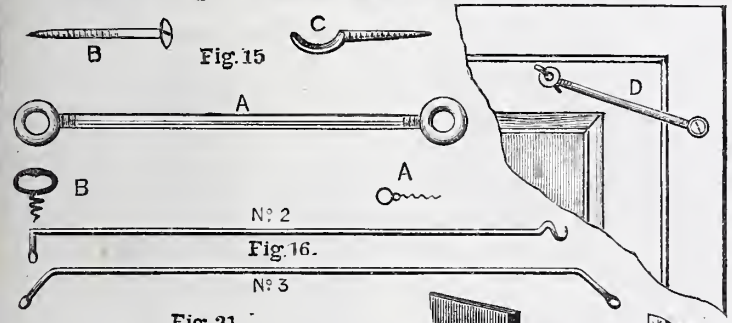

Fig. 15

Fig. 16.

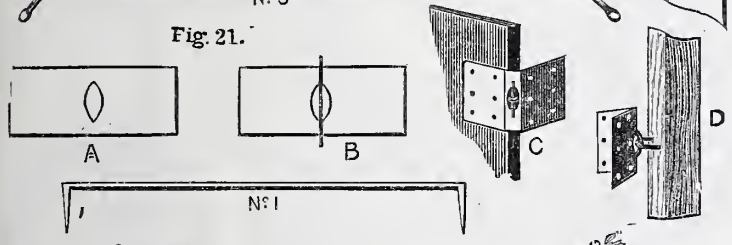

Fig. 21.

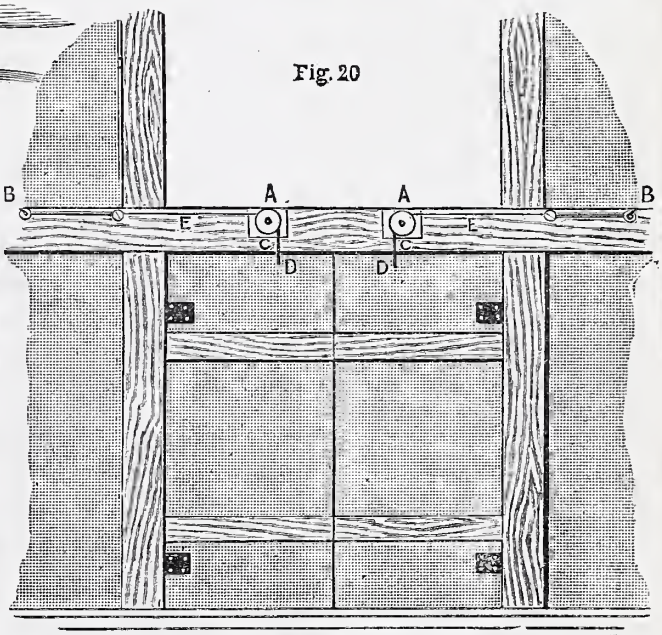

Fig. 20

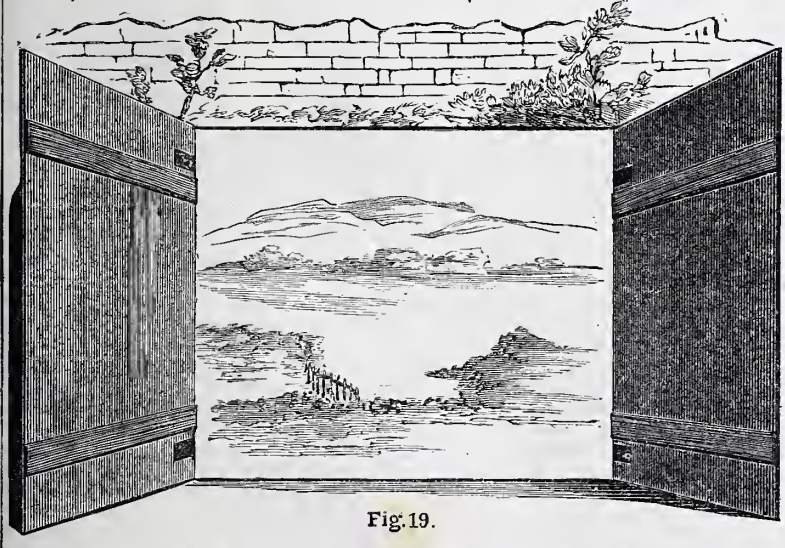

Fig. 19.

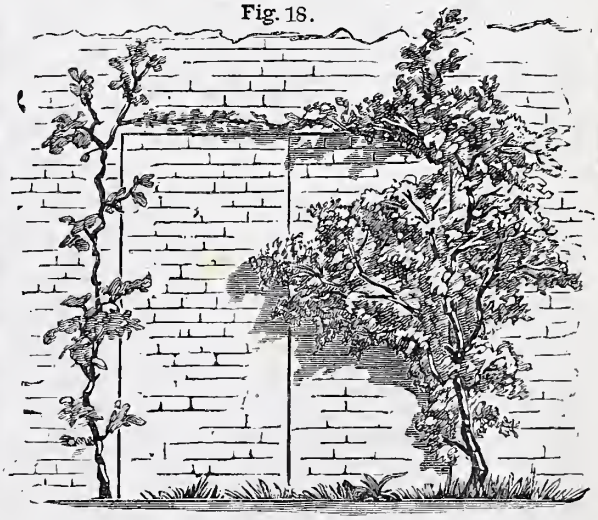

Fig. 18.

Fig. 14.—Cottage with Practical Door and Window. Fig. 15.—Springs. Fig. 16.—Dogs. Fig. 17.—Part of Set Scene secured by Dogs. Fig. 18.—Vampire in Garden Wall. Fig. 19.—Vampire Open. Fig. 20.—Back of Vampire. Fig. 21.—Diagram showing how to make Hinges.

of "vampires." They may be doors, windows, or the walls of the house or set piece, such as garden walls, the trunks of trees, rocks—in fact, anything may be made to open or close directly the actor in the scene passes through. For instance, jumping through a window from the stage and rolling back through the brick wall under the window. The "vampire" is usually made with two profile boards, hinged to a frame, each one having a rubber spring, A, as in Fig. 15, fixed on the inside, which closes the vampire so quickly that the audience hardly see the working of it. In Fig. 18 we have a vampire in a garden wall; the square lines and the line down the centre show the vampire closed. In a scene on the stage these lines would not show if painted properly. Fig. 19 shows the vampire open. It must be understood that the doors seldom come back as far as shown in the drawing, the vampire pressing against the individual passing through and closing the moment they are released. In Fig. 20 is shown the back of the vampire: the open part at the top might represent a window, cupboard, pier-glass, clock-face—in fact, it might be anything, as we see in pantomimes, in which the clown will go through and roll out of the vampire, followed by policemen and others in quick succession. I will now explain the way the vampire is made to act. In Fig. 20, A, A, shows two small grooved wheels, such as are used for Venetian blinds. Cut out two mortise holes so that the wheels work in the centre on a pin. Bore a hole through at C so that the trick-line over the wheel passes through it and makes it fast to the two doors at D, D; cut a groove out of the top of the framework at E E, so that the trick-line may lay in it; this keeps the line away from the hands and feet of the party jumping through. The line is attached to the indiarubber springs, B, B. When the jump is higher up than represented at Fig. 20, or when in a wall, as Fig. 18, no groove need be cut out at E E, as the line and spring may be placed higher up.

*Hinges for Vampires.*—Fig. 21 shows how to make the hinges. Cut a piece of tin about 4 in. long and 2 in. wide, make an oval hole in the middle, as at A, then cut a piece of stout wire a little longer than the plate is wide; solder this to the tin, turn the two ends over and solder them down, as shown in B. Now bend the plate round the edge of the vampire door, as at C; after bending it to the shape of the edge of the door, take a small staple, place the hinge against the frame of the vampire in its proper position, and drive the staple over the wire and through the hole; the hinge will now be ready to receive the door, as at D. The staple should be driven in as far as possible, to admit of the door working close and easy.

It may be objected by some reader of Work that, although practical doors and windows are and must be used in scenery constructed for amateur theatricals, yet the pieces that are played are not such as involve the introduction of vampires as an absolute necessity. Everyone, however, who urges this objection must kindly bear in mind that these papers are not written in the interest of amateur performers only, but for those who are, or desire to be, professional scene painters; and who, possibly, are, and have been, unable to obtain instruction at first starting. Moreover, in entertainments, and especially in pieces based on fairy tales, a vampire is most desirable for the introduction of all characters who have to come and go with the utmost rapidity.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

### 94.—"The Art of Graining and Imitating Woods."

In Vol. III., page 90, of Work, I noticed at some length Parts I., II., and III. of "The Art of Graining and Imitating Woods," produced by the Decorative Art Journal Company, Manchester, and I dwelt then and there on the nature, aim, scope, and character of the work itself, the beauty of the colour printing, and the wonderful fidelity with which various kinds of wood were portrayed as guides for the inexperienced and unpractised hands in their endeavours to carry out the instructions conveyed in the text, and the comparison of the results obtained with the results that should be produced by means of the specimens of colour printing that are placed in the worker's hands. Part IV., which completes the work, and with which a title page and index to the whole are given, contains fine and striking representations of pollard oak, brown oak, and satin wood; a fine inlaid panel exhibiting a rosewood ground inlaid with tulip, ivory, and boxwood, and enriched with painted decorative work; studies in maple graining showing the progressive work in various stages; studies of mahogany in three stages of the work, and other studies of the same wood when roughed in with the tool; an oak door complete with suggestions at the sides for treatment of dado; and—a study most useful in itself, especially for beginners—examples for grounds of various woods. The entire volume is most valuable, both as a technical work and a work of art, and should be found in the hands of every professional grainer.

### 95.—Hollier's Safety Stand and Home Trainer.

As very many readers of Work are cyclists, and as much interest has been evinced in the papers relating to cycles which have appeared from time to time in the pages of this Magazine, it will not be out of place to call attention to a new contrivance by which the attainment of a double purpose is secured, namely, the provision of a safe and convenient stand for the bicycle—I should say, safety bicycle—when not in use, and means whereby the yet unpractised beginner may learn to ride on his own machine, and get used to pedalling without risk of doing any injury to either the machine or himself when learning to ride. The appliance to which I am referring is known as Hollier's "Safety Stand and Home Trainer," and is illustrated in the accompanying engravings, of which Fig. 1 shows the Safety Stand with a safety bicycle placed upon it, and Fig. 2 the bicycle, thus placed, utilised for home training. That a good stand for a bicycle is a desirable thing for every cyclist who owns a machine to have is undeniable, for by its use both wheels are always kept in the same plane, and it is raised above the level of the ground, which is a better position for cleaning and oiling, and takes off much of the strain and tension of the framework which must result from allowing the machine to rest continually on the parts—I had almost said points—of the tires of the front and back wheels where the wheels come in contact with the surface on which the cycle is standing. Regarded as a home trainer, when the machine is fixed and mounted on the stand, the weight of the rider brings down the back wheel on to a pulley, which revolves, and is regulated to work hard or easy by means of two brakes and movable weights on each side, as shown in Fig. 1 and also in Fig. 2. The distance covered may be indicated, if desired, by a crank log or cyclometer, but this adjunct is not supplied with the stand, and forms an extra. The advantages claimed for the Safety Stand, which has been patented by Mr. Hollier, are:—First, that every person who has a machine may, by purchasing one of the stands, have a home trainer complete at the cost only of the stand itself, which is estimated at about one-third the cost of those already in the market; secondly, the supports are not fixtures, and the machine can be placed on them and removed in less than a

Fig. 1.—Bicycle on Hollier's Safety Stand.

Fig. 2.—Bicycle on Stand for Home Training.

minute, and the stand placed away, occupying but little space when not in use; thirdly, the stand, or stands—for there are two in reality—supply a great want to learners in practising pedalling, which, when thoroughly mastered, overcomes one of the beginner's chief difficulties; and fourthly and lastly, as a stand simply for cleaning, oiling, repairing, etc., the supports are most desirable, because, when the cycle is raised on them, the wheels are free and elevated, and they are stable in themselves from their construction, and save any undue stooping. The supports are so constructed as to adapt themselves to any kind of machine and width of tire.

The Editor.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Rate of Circular Saws.**—A. R. (*Scorrier*) writes in reply to Chopstick (see No. 135, p. 491 of Work):—"I might say that I am not the proprietor of the Scorrier Saw Mills, but am pleased to say that what I have written in reference to circular and hand saws is the result of experience; and I am of opinion that there are not many men within the last twenty years who have had greater experience in circular, frame, band, and hand saws than myself. Again, I do not sneer at home-made machinery. We have a home-made machine, and it does its work well; but there are many home-made and factory-made machines that are not worth their room, especially when driven by hand. In reference to a rip saw cutting 3 in. pine, what I said was that the joiner for whom I sharpened the saw said he had been cutting 2½ in. and 3 in. pine with it two days. I don't suppose the man meant that he was continually cutting with it, but that was his principal work for the two days. Time must be allowed to prepare his work; and I argue that a good hand saw, well sharpened, would cut in clean pine most of the two days before being re-sharpened. Of course, if you use an inferior tool it has to be sharpened often. Chopstick let the cat out of the bag when he said he could saw as much 3 in. deal in one day as six men with the hand rip saw, with a labourer to turn the wheel. I suppose he meant if the poor labourer could continue to turn the wheel at a good speed! Since my reply to Chopstick on p. 379, more than one reader of Work has said to me, 'I was pleased to see your reply to Chopstick, and quite concur with what you said in reference to driving a circular saw by hand.' Again, I think there would be no difficulty in Chopstick getting a job in a respectable joiner's shop, where there is a small circular saw to be driven by hand, if he would take his labourer with him to turn the wheel—even if they only do the work of three men with the hand rip saw, leaving six men quite out of the question. Perhaps Chopstick will say (using his own words—see p. 398) whether, if I should he wanted to cut 3 in. deep, I should require two labourers, as it would be hard work for one. I, for one, should be pleased to see a description of Chopstick's saw bench, and how he can cut 3 in. deep so much easier than those I have seen at work; and I have seen many."

**Fiddle Making in Earnest.**—A. X. E. (*Nottingham*), an esteemed correspondent to Work, sends the following cutting from a local paper, thinking, no doubt, that it will amuse some of his fellow-readers. We think so too; for which reason a little editorial license is granted in this case:—"At the Leigh County Court, the case of Beaumont *v.* Medling came on for hearing. This was a claim for teaching the defendant how to make violins, and also how to play the same from music. Mr. Grundy represented the plaintiff, and Mr. Whittingham defended. Plaintiff's case was that he told defendant what kind of wood was necessary, and he replied that he had two beech planks in the back yard, which would do for the body of the double-bass, and an old cart-shaft, which would do for the neck. Defendant also purchased some deal, and the instructions began. Defendant was in a great hurry to finish the instrument; and when he had finished gluing the belly, it was found that he had forgotten to take out the glue-pot. (Laughter.) The neck was made from the cart-shaft, according to instructions; but defendant fixed it on the wrong end of the instrument. After everything was prepared for the strings, plaintiff told defendant to go to a music shop for them; but, instead of doing so, he went to a watchmaker's, and got the catgut rope of an eight-day clock. (Laughter.) He put this string on, and when he was winding it up to tune the fiddle, the string broke, struck him in the face, and gave him a black eye. (Renewed laughter.) When all was completed, it was found that defendant had made the instrument so large that he could not get it out of the room.—After hearing a mass of evidence on both sides, his honour gave judgment for the plaintiff for £3 16s., and for defendant, on a counter-claim, for 3s. 6d., which had been paid into court."

**Air Pump.**—A Correction.—O. B. (*Preston*) writes:—"Please read 'Sprengel' for 'Springle,' on p. 497, Vol. III. The mistake was not observed in reading proof. And Mawson & Swan's 'operator,' at foot of front page, should read 'aspirator,' as in the text of the articles. As I did not see the proof of the illustration, I had no means of correcting it."

**Blacklead.**—H. B. S. (*Liverpool*) writes:—"In Work, Vol. III., p. 509, is an answer to H. P. by F. P., in which, in the interest of the correspondent, I would like to make one or two corrections. The chemical name for blacklead is carbon; the terms blacklead, plumbago, and graphite are technical terms for one particular form, or, as it is called, allotropic modification of carbon. Plumbago is not an oxide of carbon; there are only two oxides of carbon: carbonic acid and carbonic oxide. F. P. should read some new text-book on chemistry, such as Roscoe's, before answering correspondents on chemical subjects. He will no doubt take this hint kindly, as it is intended."

### II.—Questions Answered by Editor and Staff.

**Patent.**—J. S. (*East Dereham*).—Before patenting, J. S. would do well to consult some person of repute in each of the trades to which his inventions belong. Such persons can best tell him whether his ideas are of any commercial value. If he fears that, by so doing, he will expose himself to piracy, and does not object to paying for the £1 stamps, he should first obtain provisional protection. He will most readily bring his inventions before the public by getting them taken up by established firms; and the necessary information as to obtaining provisional protection and patents he will find in the article on "Taking out a Patent" in Work, Vol. I., p. 545.—C. C. C.

**A Patent.**—One from the Start.—Your invention appears to be one by which a considerable saving in time in office work might be effected, and as the article is to be purchased at so small a cost, it ought to have a good chance of success. You cannot do better than first obtain provisional protection (see Work, Vol. I., p. 545), and then offer it to some well-known firm which manufactures such things—say, such as Messrs. Perry & Co.—C. C. C.

**Shipping Models.**—Toymaker.—You will be able to get anything you want in the way of model boat fittings from any of the following firms, who would probably name prices in the ordinary way of business if you apply to them:—Stevens, Model Dockyard, Aldgate, London; John Bateman & Co., 131, High Holborn; John Sowles & Co., 75, Queen Victoria Street, London; Hitchen & Squire, 36, South Castle Street, Liverpool. When you ask us to give you prices of "rigging and deck fittings of small model steamships or sailing ships," I wonder if you think there is unlimited space in "Shop," and that we have nothing to do but collate price-lists. The best way, when you or anyone else wants to know the price of anything, is to write to dealers. The names of these we are always happy to give; but it is quite another matter to give prices of a few hundred articles, when perhaps only half a dozen are wanted by the inquirer. If you had specified what you wanted, we might have helped you.—D. D.

**Frame Moulding.**—W. S. B. (*Leeds*).—You can get D. F. O. G. rosewood, as your sample, of City Frame Company, 29, Basinghall Street, E.C., who are sole makers of this article. We have sent your letter, with request to give you their trade terms, which, no doubt, they have complied with.—G. R.

**Mitre-Cutting Machine.**—Nemo.—In reply to yours, Messrs. Booth Bros., Dublin, are the patentees of the mitre-cutting machine. You can get it through any respectable tool maker of your town, price 15s. complete.—G. R.

**Moulding Composition.**—Gala.—The moulding composition used in rubber-stamp making consists of a mixture of china-clay and French chalk, kneaded with water to a stiff "dough;" two parts of clay to one part of chalk will answer very well, but the proportions may be considerably varied. Considering the cost of materials when purchased in small quantities, and the labour of mixing it is better to purchase the compo. ready prepared. Some wholesale houses, as the London Rubber Printing Company, 33, Cheapside, London, E.C., sell the compo. in the dry state, so reducing expense when cost of carriage has to be incurred. The above-named firm supply handles and all other stamp-making accessories wholesale.—Qui Vive.

**Stamps.**—F. G. H. B. (*Rowley Regis*).—It is quite "possible for an amateur to make indiarubber stamps in his own handwriting." To perform this apparently puzzling feat, it is necessary to procure a *fac-simile* block from an engraver in wood or metal, and use the block instead of type. The name to be copied is written, preferably with copying or lithographer's transfer ink, and transferred to the blank block of wood or metal by laying its face in contact with the block, and applying some little pressure. By this means sufficient ink is transferred to the block to give a clear outline of the matter to be copied—reversed, of course—and the bare metal is then removed by the aid of gravers. With a little perseverance, F. G. H. B. might manage such a job for himself.—Qui Vive.

**Iron Work.**—J. M. (*No Address*).—Bradley, 180, Fulham Road, West Brompton, sells the iron.—J.

**Violin Case.**—A Reader of "Work."—A description of how to make a violin case appeared in No. 131 of Work.

**Waltham Watch Parts.**—W. P. (*Dundee*).—Apply to the Waltham Watch Depôt, Holborn Circus, London, E.C.

**Telescopes.**—J. J. M. (*Liverpool*).—It would occupy too much of "Shop" space to reply adequately to your question there. Please await Vol. IV. of Work, when it is hoped the subject of telescope construction will be exhaustively treated.

**A Self-acting Fountain.**—Hydrostatic.—A fountain constructed upon the lines of your sketch would be quite useless. An illustrated article upon the construction of a self-acting fountain is in the hands of the Editor, awaiting space for publication, which will give you full particulars as to principle and method of construction.—C. M. W.

**Graph Solution.**—T. S. (*Huddersfield*).—I have not been able to try the solution you give; but, of course, indiarubber will not dissolve in water. You do not say whether you applied heat or not. I should be inclined to add sufficient methylated spirit to the rubber to dissolve it; add the gelatine next, and stir in the glycerine, oxalic acid, and water, mixed together, both solutions being warmed. The spirit will ultimately evaporate when the plate has been poured and cooled, leaving the ingredients you mention. If this does not answer, write again, and I will try to find time to make the experiment, and let you know the result.—J. W. H.

**Artificial Eyes.**—Justice.—A guinea each for artificial eyes, to fit exactly and match the other optic, is the ordinary price; and even much higher prices are charged, as they are frequently painted from life to match in colour. Of course, it is not the material but the highly skilled labour that makes the price appear disproportionate. Glass eyes, such as are used for wax-work figures, human life size, any colour, may be bought for half a crown a pair, whilst those for large wax dolls, for about thirteen to fourteen pence a pair, from Meeke, Westminster Bridge Road, or Wheelhouse, Waterloo Road. On inquiry at Mr. Grossmith's, 175, Fleet Street, E.C. (the oldest house in the trade, established 1760), we find that if a second quality be required, made by German artists, the price is 10s. each, if selected from stock, or 15s. each if made to order; and if the eye he sent to be re-enamelled, the cost is 5s. I am also informed that a movement is obtained, in the best quality, at £1 each, if selected from stock, precisely in accordance with the action of the natural eye; and that they can be fitted in a few minutes without pain or operation. As to your second question, I cannot say at all when articles on coach-building will appear in Work.—J. W. H.

**Hammock.**—J. R. W. (*Portsmouth*) asks me what size to make a hammock for his brother; but as he does not give me the size of his brother, I cannot help him further than to say that the usual size is 6 ft. long by 2 ft. wide, exclusive of rope for suspension. I have seen grass hammocks sold in New Oxford Street at 1s. 6d. each, but do not remember the address. At a seaport such as Portsmouth, I should have thought J. R. W. could easily have obtained the information he requires from the store-dealers and others.—J. W. H.

**Stereo Plates.**—Amateur Stereo.—I cannot see the cause of your failure, and can only suppose you have not followed the instructions. I advise you to write to the firm who supply your metal. Perhaps they have sent you metal intended for other purposes instead of paper process metal, which differs from that used for plaster, for backing electrotypes, or for casting type, etc., all of which also differ. I am almost inclined to think that your metal is dirty. Keep stirring it well at the proper heat—that is, when it will just scorch, but not light, a piece of brown paper. Some put a pinch of salt or a piece of resin in, to kill the sulphur and make the scum rise. A few drops of fatty oil also help. Then skim it well until the metal is quite clean, and pour at the heat indicated.—J. W. H.

**Besom Makers.**—£ S. D.—I have inquired in vain and looked over several directories for name and address of such. I hear the gipsies make them in the forests, but can obtain no information. Perhaps some Work reader may be able to throw some light upon the matter.—J. W. H.

**Metal Soldiers.**—L. A. C. (*Wigan*).—If the toy soldiers you refer to as so largely imported from Germany are to be made as an experiment, I think I can give you some assistance; but if you wish to try to establish it as a business in competition with the present makers, I could not guarantee that I know enough about the trade to give reliable help, and should advise you to take a trip to Nuremburg, where you could easily get to know how it is done and made to pay. The moulds—for they are evidently cast—are, I should say, electrotype matrices, made by depositing copper upon wax models, coated first with plumbago, made to part in the central plane of the figure into two halves. This may be done by modelling each side separately, and putting a strip of sheet gutta-percha between them, or they may be electrotyped separately. The metal may be any of the ordinary fusible alloys, which consist of lead, tin, and bismuth. Bismuth melts at 267°, lead at 334°, and tin at 228°, only 16° above boiling point of water. Equal parts of each would melt, therefore, at about 276°. The more tin and less lead you use, the lower the melting point and the greater the cost. For painting, use ordinary tubes of oil-colour, mixed with copal varnish, and lay it on with a sable brush (not a hog's-hair). I do not know of any book on the subject; but I fancy that a similar industry exists in Birmingham. Let me add that a slight pressure of the two halves of the mould will be necessary when poured; and perhaps they are hinged together, as in the case of casting type, and the mould held head downwards as the hot metal is poured, and an upward jerk given to force the metal into all the parts of the mould, which, in a few seconds, could be opened, and the figure shaken out of it, as the metal soon cools.—J. W. H.

**Coopering.**—J. S. (*Longsight*).—The prices paid for repairs, and for butts, puncheons, etc., vary in

different towns and at different times. I am afraid, therefore, that I can only advise J. S. to pump coopers in and around Manchester for the information he requires.—J. W. H.

**Stair Block Wood.**—J. P. A. (*Walthamstow*).—The "square blocks" you refer to are cut out of teak, as this wood will stand a lot of hard wear; although I think that "Jarreh" wood would last just as long and at a less cost, being cheaper than teak. It is now being used for wood-paving in many of the principal streets of London.—A. J. H.

**Astronomical Telescope.**—J. J. M. (*Liverpool*).—Although your questions are well put, practical replies to each one—that is to say, supposing you wish to construct a serviceable achromatic telescope—would occupy much more space than can at present be accorded in these columns; but if you merely wish to make a simple form of cheap chromatic telescope, you might carry out the following directions: First, procure or make a brass or zinc tube, to measure 53 in. long and about 3½ in. in diameter, and, after first making the ends quite true, solder a diaphragm, having a 2 in. aperture, at about 8 in. from one end of the tube. Now proceed to fit the 3 in. object glass into a turned wooden cell, retaining the lens in position by means of a ring of springy brass wire; after which the cell is tightly fitted into the end of the body tube nearest to the diaphragm. The draw tube must draw through a wooden collar, which is turned in a lathe to a suitable size, and fitted to the other end of the body tube. This collar should be furnished with a 1¼ in. opening in the middle, to receive the draw tube, which must be made of brass, about 12 or 14 in. long. The best form of eye-piece to use will be the Huyghenian, which is composed of a couple of plano-convex lenses of 1 in. and 3 in. focus, mounted 2 in. apart, with the latter next to the object glass, and the plane sides of both the lenses outwards. The lenses are mounted in a suitable length of brass tubing, with a small diaphragm, having an aperture about equal to the diameter of the eye-lens placed midway between them; after which the eye-piece is slid into the draw tube of the telescope, with a small wooden cap, lastly, fitted on to the outer end. This cap should be furnished with but a small aperture, as it is only the centre of the lens that is used. The interior of the tubes, including the cells of the lenses, should receive a coating of dull or dead black. An eye-piece of this description will have a magnifying power equal to a single lens of 1½ in. focus, so that the telescope will magnify forty times. Although this telescope is extremely simple, it will be capable of doing good work, and will show Jupiter's moons, and, probably, some traces of his belts, as also Saturn's rings. As you ask to be referred to some articles on telescope making, mention may be made of the article on "A Four-draw Telescope," which appeared in WORK, No. 142. Opinions differ as to the relative merits of refracting and reflecting telescopes; but the latter will be found the cheapest to make—if this is any advantage. Messrs. Lancaster & Son, of Colmore Row, Birmingham, used to supply amateurs with sets of lenses for the construction of astronomical telescopes, together with lithographed diagrams and instructions for mounting. As above, with a 3 in. object glass of 50 in., from 5s. 6d.; or, with an achromatic object glass 2⅝ in., £2 15s.; and 3 in. object glass, £4 10s. You could also procure the lenses cheap from Prof. Caplatzi, Chenies Street, London, W.C. I quote the following from an old list: Ordinary chromatic object glass, 3 in. diameter, 3s. to 4s.; eye-piece lenses, 1s. each; achromatic object glass, 2¼ in., 25s.; 3 in. ditto, 40s. to 50s. Wholesale firms do not care to supply amateurs; otherwise, some of these lenses would cost considerably less.—C. A. P.

**Telescope.**—T. M. (*Liverpool*).—You probably require a short monocular telescope. The object glass would be 1¾ in. in diameter, and be fitted with a pan-centric eye-piece. A glass of this description would be capable of showing the time by a church clock at six miles, or a flag at twenty miles. The lenses would, however, be expensive. A full set of lenses, including an achromatic object glass and erecting eye-piece, for a telescope of a more simple form, to do what you require, would cost between 3s. and 4s. Full directions for making telescopes of either form would occupy too much space in these columns, and must, therefore, remain until space can be spared for a series of papers on the construction of telescopes of various forms. In the meantime, you might write to The Science Exchange, Chenies Street, London, W.C. Write fully, stating your wants clearly, and they will be able to supply you cheaply, and, moreover, give you advice if needed.—C. A. P.

**Metal for Gilding.**—T. R. (*Sheffield*).—For all descriptions of leaf metal for gilding purposes, write Mr. James Smith, Bridge Street, Manchester. I am not familiar with "bundles" of German metal, as described by you; but it is probably put up in that form for some particular class of work. All metal—either pure or base—that I have handled has been in books. Respecting the keeping qualities of imitation gold, this chiefly depends upon the atmosphere. If well lacquered over with a solution of shellac in spirits, it will keep its colour almost as well as gold-leaf; but for picture frames and fancy articles for our personal service and use, it is well worth the extra money for the genuine article. The specimen you send is of the commonest quality. A very good imitation gold—or "ducat," 'tis often called—can be bought for 3d. and 4d. per book. Picture frames (German) are gilded with "white metal," and lacquered with a yellow-stained spirit solution. All articles appertaining to gilding, Mr. Smith (as above), or Pavitt & Sons, Southampton Row, London, will supply at fair prices, and of reliable quality.—F. P.

**Bunsen Gas Burner.**—T. M. (*Liverpool*).—The great mistake in your query, and what makes it impossible for me to answer, is that you have not stated *how much glass you want to melt*, and whether you use a furnace or not. I cannot by any means tell how to arrange one, and what size to make it, until the above is answered. The amount of heat given out by a burner is proportionate to the size of the flame when burning properly. There are only so many units of heat in the flame of a burner of a given size; but this flame can be concentrated, by means of a blowpipe or the blast in a furnace, so that it will melt objects which, without this means, it would not have much effect on. Do you want to use it in a specially constructed furnace, or otherwise? as I am afraid you will not be able to melt glass in any quantity without the aid of a furnace. A very small size of burner, or even a candle or lamp flame, in combination with a blowpipe, would be ample, I should say, if the amount of glass was very small. If you want to use it in a furnace, a great deal lies in the design of the furnace itself. The best thing I can do is, therefore, to give a sketch of a Bunsen burner furnace for metals, with crucible in position, and the position and size of the top of the burner. From this and Fig. 2, which shows an ordinary burner, you should be able to design one to meet your requirements, making the diameter of the burner tube proportionate to the crucible, as in Fig. 1. You must first get a crucible that will hold the amount of glass you want to melt, and proportion the top of burner to it. If the flame alone from the burner does not melt the glass in crucible, perhaps

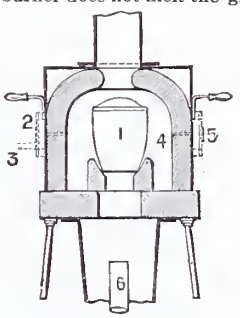

Fig. 1.—Section through a Bunsen Burner Furnace—1. Crucible; 2, Air Chamber round Cupola; 3, Entrance for Blast; 4, Slits round Cupola; 5, Small Door; 6, Burner Top.

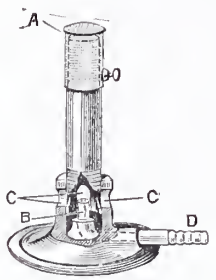

Fig. 2.—Bunsen Burner, Perspective View, partly in Section—A, Removable Perforated Metal Cap; B, Brass Burner; C, Air Inlet; D, Pipe for Indiarubber Tube.

by concentrating the flame on to it by means of a blast you might be successful. This could be arranged, as shown by dotted lines, Fig. 1, by cutting slits at intervals (the longer the better, if the furnace will stand it) round the cupola: these slits to be from $\frac{1}{16}$ in. deep and upwards, according to the size of the furnace. A narrow chamber, shown in dotted lines, Fig. 1, might be formed, completely encircling the cupola and enclosing the slits. By having this chamber rather deep, the blast is heated to a certain extent before entering the furnace proper. The blast, if the furnace is no greater than 6 in. by 6 in., might be produced by a pair of ordinary house bellows; if larger, by bellows worked by the foot or a small fan. At intervals round the outer casing, and opposite the slits, it is as well to have small doors, to clean out the slits should they get filled up by dirt. Perhaps it would be as well to have the slits slightly inclined upwards, by which means the flame will be blown both against the sides of the crucible and upwards, thus creating a draught as well. Fig. 2 shows a perspective sketch of a burner, partly in section, to show more clearly the method of distributing the gas and the position of the air-holes, of which there are four, placed at right angles, passing through both stand and tube, which is threaded to screw into stand; and by this means the admission of air can be regulated to a nicety by turning the tube round. Suppose perforated cap removed, as it is only a useful accessory: then you turn on the gas, which passes up the tube, taking with it air for its own consumption. If there is too little gas passing up, it will not burn at the top of the tube when a light is applied, but descend and burn below. This will show you that there is too little gas. The quantity being sufficient, the flame will remain burning at the top. Should there be too little air, the flame becomes golden; when burning correctly, it should be blue. When the finely perforated cap is used, a very inflammable mixture of gas and air can be thus burned, as the gas, whatever its pressure quantity or quality, cannot light below. By this means a burner can be made from 1 to 2 in. in diameter, and capable of burning 40 cubic feet of gas per hour. I have only mentioned this as a useful accessory. The proportion of a small tube in a burner should be from 4 in. to 5 in. long by ⅜ in. to ½ in. in diameter.—P. B. H.

**Whitewash from Wall.**—W. H. (*London, S.W.*).—The only recipe for removing this that I am aware of is a stiff brush and plenty of hot water and "elbow grease." I should say the simplest way to rid yourself of this eyesore would be to give it a coat of paint. Any old stuff, or even common tinned paint, would answer, so long as it dries well. Some dry Venetian red and common black, mixed with linseed oil and driers, would also make a cheap mixture, and of suitable colour.—F. P.

**Folding Picture Screen.**—A. H. B. (*Stalybridge*) should get No. 89, and in it, at p. 600, he will find answers to his queries. I imagine that he will find the varnish sold at the oilman's as "paper varnish" sufficient for his purpose; but if he is particular, he can get the more expensive "mastic varnish" from the artists' colourman's.—S. W.

**Making a Chess-Board.**—R. W. M. (*Carbury*).—I am sorry your query was overlooked. Even now I cannot tell you "how to remove scraps from screen" without knowing what the scraps are made of, or what the screen is, or how they are stuck on. If they are paper scraps, can you not soak them off? Since you ask the price of eight numbers of WORK and an index, I can only say they are one penny each; and if you will weigh nine of your own numbers, you can easily tell what the postage will be. To make a chess-board, you will require thirty-two squares of dark and thirty-two of light wood—holly, say, for the light, and then almost any coloured wood will do for the dark squares: say, rosewood. The squares may be about ⅛ in. thick. Prepare two pieces of wood, one of light wood and the other of dark wood, each 6 in. long, and exactly square in section—say, 1½ in. square—for a board one foot square. Now, if you have a circular saw you can saw off the thin squares one after another; if not, make a kind of trough of wood, with the sides cut through, perfectly square with the length; lay the prepared blocks of wood in the trough, and saw them up. Then have a board of sound wood ready to glue them down on; glue on strips round the edge, and smooth the top by rubbing down with coarse sand-paper; then smooth with fine sand-paper, and finish with French polish.—F. A. M.

**Violoncello.**—J. D. (*Glasgow*).—You would be wasting your time in making a 'cello from the outline pattern you send. The corners are very weak indeed; the *ff* holes have also a decidedly "amateurish" look about them. The measurements you desire are as follows: thickness of belly at jointing edge, 1½ in.; thickness of back, 1 in.; width of ribs, 4½ in.; thickness of ditto, $\frac{3}{4}$ in. The dimensions of the neck have already been given.—B.

**Lancaster Camera.**—F. M. (*Liverpool*).—The reason is *insufficient* exposure. To take portraits with magnesium, it is necessary to have a fairly quick-acting lens—say, an ordinary portrait combination—working with a wide aperture. With landscape lenses, the stops are necessarily small; therefore, much more light is required, also quick plates and strong development, to get a properly exposed picture. There should also be plenty of white reflectors about—as sheets, paper, etc.—to throw light into the shadowed parts of the subject. A good deal of skill is required to make *satisfactory* portraits with magnesium light, even with the best lenses.—D.

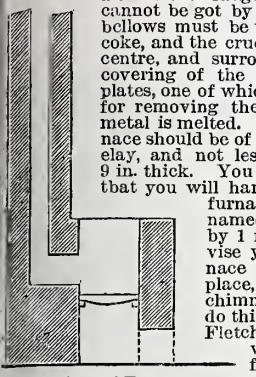
**Musical Instrument.**—A. B. (*Basford*).—The instrument, of which you send a drawing, belongs to the time of the Empire, and is known as a harp-guitar, from the shell or body being shaped after the harp fashion. I regret I cannot tell you the correct way of tuning it, as that is a matter of great uncertainty; but most likely it was tuned as the ordinary guitar, with the additional outside bass strings an octave lower than the fourth, fifth, and sixth. These instruments have gone quite out of date, and are now of no particular interest or value except to a collector. I should think it would be useless trying to get an "instructor" for it, it being, as a musical instrument, obsolete.—R. F.

**Varnish for Zither.**—CLERICUS.—Varnish does not give very satisfactory results; the instrument should be French polished, as this admits of a very much better finish, especially if the belly is of maple or rosewood. Varnish, especially spirit varnish, shows every little scratch or chip, and soon wears rough; and, from its drying so quickly when applied, it is difficult to get a good finish with it when spread over a flat surface. The breaking of the strings can hardly be attributed to one specific reason, but may proceed from one of many. Thus, the slot in the saddle may be rough; the holes in the wrest-pins may be sharp on the edges; or the angle of tension between the wrest-pins and the upper bridge-pins may be too great; or the fault may lay in the strings themselves. If the breakage results from the first of these causes, it would occur at the saddle; examine it, and if any roughness exists, smooth it away with a fine file or piece of folded glass paper. The second would cause the breakage at the pin; the third, at the upper bridge; and the fourth, just anywhere in its length, between bridges. Finally, it may proceed from the fault of the tuner, in mistaking the pitch, and so trying to pull the string up above the note for which it is intended.—R. F.

**Fortune-Telling Card.**—AMATEUR.—This is in hand, but, being too lengthy for "Shop," you must wait until room can be found for it in the body of WORK.

**Electro-motive Engine.**—POINTSMAN.—It would be impossible to tell you in a few sentences how to make one. You should read an elementary treatise on electricity, and then get "Electro-Motors: How Made, and How Used," by S. R. Bottone, price 3s.—F. A. M.

**Small Furnace.**—T. A. E. (*Clapham*).—I send sketch of furnace, such as is generally used for melting brass, and which I suppose will be what you want. The air is admitted under the bars, and a flue of 15 ft. or 20 ft. in height is required to cause a sufficient draught; when the draught cannot be got by a chimney, a fan or bellows must be used. The fire is of coke, and the crucibles are set in the centre, and surrounded with it. The covering of the furnace is of metal plates, one of which is arranged to lift for removing the crucibles when the metal is melted. The walls of the furnace should be of fire-brick set in fire-clay, and not less than one brick, or 9 in. thick. You will see from this that you will hardly be able to get a furnace in the space named by you—viz., 2 ft. by 1 ft. 6 in. I should advise you to build the furnace in front of the fireplace, and use the flue as a chimney, or if you cannot do this, write to Mr. Thos. Fletcher, of Warrington, who supplies small furnaces for this purpose, which are heated by gas, and which will be much cleaner in a house.—M.



Section of Furnace.

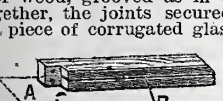
**Working Alabaster.**—R. N. (*Grays*).—There is some information in Holtzapffel's "Mechanical Manipulation." In Vol. I., p. 164, I find that alabaster is sulphate of lime, or compact gypsum, found near Derby. But few tools are required for turning it: point tools for roughing out, and ordinary strong carpenters' chisels, ground straight for straight work, and rounded for turning hollows. Of course, the cutting angles would be more obtuse, and stronger, than for wood. Alabaster may be finished by fish-skin or Dutch rush. On pp. 1033 and 1034 of Vol. III. there is further information as to polishing; but I do not see if it should be turned wet or dry. Alabaster may be polished in the lathe by soft sandstone and water, rubbed in with a rag; then, after washing, by putty-powder and water applied in the same way; finally, with putty-powder and soap and water. It is also worked by the methods of the lapidary. It is about as hard as jet, copper, or soft brass; and, therefore, the dust would injure a soft steel mandrel, working in gun-metal collar, but should not have much effect on a hard steel mandrel. Perhaps someone will supplement this who can speak from experience.—F. A. M.

**Design.**—A. N. (*Horwich*).—I have sketched you a simple design, occupying one corner of the square you send; but whether it is "nice" or not, it is for you to say. I do not pretend to do much in this way, and would refer you to numerous designs, and their parts, in back numbers, such as "London Decorator's" portrayals of ceilings, etc. Surely it is not difficult to discover something suitable in the vast quantity of matter contained in WORK and your fret-work catalogues! If not, I fear that, unless you specifically state in what direction your taste lies (whether for scroll-work, flower or geometrical patterns), difficulty will be experienced in pleasing you.—J. S.

Design.

**Boot and Shoe Repairing.**—H. B. (*Accrington*).—Papers on this subject appeared in WORK, Nos. 12, 117, 122, 126, 130.

**Enlarging Cameras.**—E. C. (*London, S.E.*).—In an article on "Photographic Appliances," now being published in WORK, full directions for constructing wooden dishes of any size will be given. Zinc dishes or metal dishes of any kind unless gilt or silvered are quite unsuitable for photographic development. Wooden ones answer every requirement, and for large-sized work are best of any. For small work, papier-mâché, ebonite, or porcelain are to be preferred on account of their being less cumbersome; otherwise they are equally good. Strips of wood, grooved as in diagram, are framed together, the joints secured with white lead, and a piece of corrugated glass slipped in the groove, and the whole, when screwed together, varnished two or three times over with shellac varnish, one coat being thoroughly dry before the application of the next. A dish thus formed will answer every purpose, and last well.—E. D.



Enlarging Cameras — A, Glass; B, Groove; C, Corner.

**Improved Bicycle Spoke.**—C. H. (*Liverpool*).—In the sketch and description submitted by your correspondent I fail to see anything new, as almost every conceivable kind of spoke and nipple have long been in the market. Neither do I see any of the advantages mentioned that are not already in use. We have wheels with hollow rims, where the spokeheads or nipples never interfere with the tire, being in the hollow between the two sections of the rim. These hollow rims are made so light, that it is neither wise nor necessary to desire them lighter. As to using nipples and nuts at the rim, the thing has been patented, as far back as 1878, by a John Samuel Smith, and many makers have used the same or similar arrangements since. As to greater facility in building, a wheel can be built and tied up in fifteen minutes by the methods at present in use.—A. S. P.

**Bicycle Wheel.**—WHEELER.—In Fig. 1, if the wheel, A, is double the size of B, which is the driver, the power is increased and the speed diminished by one-half. In Fig. 2, where the larger wheel is the driver, the speed is increased and the power diminished in the same proportion. To put it more clearly, say the two wheels in Fig. 1 are each 6 in., and they are geared together by a band or chain, it should be clear to the dullest intellect that, when driven, they both would have the same speed. Increase A to double the size of B, and one revolution of B will only be a half revolution of A, and will only require half the power to do it. Drive the larger wheel as in Fig. 2, and one revolution will be two of the smaller wheel, C, and will require double the power to accomplish it. See pages 34 and 100, Vol. III.—A. S. P.

**Patents in Bicycles.**—V. L. (*Newcastle-on-Tyne*).—Anyone beginning cycle building has a large field to work in without infringing any patent. There is no patent cycle. There are patent parts or fittings, such as bearings, saddles, etc.; but these are usually bought by makers from the patentees or dealers at the prices they put upon them. Get the *Cyclist*, where many dealers and makers advertise, where you will find addresses, and can get catalogues and information from any maker of a machine you wish to copy. Or, if you wish to avoid being a copyist, and design for yourself, then you are independent of all makers. To get some information regarding nearly every machine made, write to the publishers of the *Cyclist*, Iliffe & Son, Coventry, where you can get the "Bicyclist's Indispensable Annual" for 2s. 10d.—A. S. P.

**Freezing Mixtures.**—J. R. W. (*Portsmouth*).—There are a great many ways of reducing the temperature of water and other substances to a point considerably below freezing; but some of them are not admissible for the purpose you require, as they give off an offensive smell; and others, again, are too expensive in use to be of any service to you. I should have thought that the usual freezing mixture of coarsely pounded ice and salt would not have been too expensive for you; 2d. per lb. is not an unusual price; for a single lb., in fact, I have paid 4d.; but, surely, you could buy a larger quantity at a much cheaper rate. However, as you ask for a freezing mixture, here is one that will give you 30° below freezing point: Take 1 lb. of muriate, or chloride of ammonium, commonly known as sal-ammoniac, and 2 lbs. of nitrate of potash, or saltpetre; pound each separately, and mix; to use, take equal parts of this mixture and of best soda, also pounded; place them in the vessel in which you have your ice pot, and pour cold water on the mixture. A little less water than it will take to dissolve the salts is the proper quantity. For 2 lbs of each, a quart of water will be sufficient. If too much water is used, which is a common fault in making these mixtures, the power of the stuff is wasted in cooling down the surplus water instead of the substances that you want to freeze. It is of no use trying to freeze with 2 or 3 ozs., and everything used should be as cold as possible at starting. The container for the mixture should be of wood, and the inner vessel of pewter, and well packed round with the mixture.—R. A.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Luminous Paint.**—R. R. (*Upholtand*) writes:—"Could any reader kindly inform me how to make luminous paint, or where it could be purchased?"

**Japanese Fiddle.**—J. M. B. (*No Address*) asks any correspondent to kindly inform him how to make a Japanese fiddle.—[This is a toy instrument.—ED.]

**Bois-Duré.**—J. S. (*Hampstead*) writes:—"Can any reader inform me what is *Bois-Duré*, and how it is made, and its application as a substitute for papier-mâché?"

**Brass Lacquering.**—L. M. (*No Address*) writes: "Will some kind reader of WORK tell me where I can send a pair of iron hames of horse-collar to be carefully re-lacquered in brass?"

**Carvers' and Gilders' Society.**—J. B. (*Bristol*) wishes for the address of secretaries to above trade societies and their branches. Perhaps professional workers in this craft will oblige with any particulars relating to London and provincial branches.

**Skates.**—JACK FROST writes:—"Will any reader kindly give me instructions for grinding my skates at home? Also, is it worth my while to do so?"

**Size.**—ONE IN A FIX writes:—"Will some reader of WORK kindly give me the ingredients for making builders' and paperhangers' size, and shoemakers' size, in proper proportions? I want to make a great quantity. I have every number of WORK since it first came out on March 23rd, 1889, but cannot find what I require."

**Hearthrugs.**—C. F. C. (*Oldham*) writes:—"Will any reader kindly tell me, through 'Shop,' where I can buy designs for hearthrugs? Also the address of the manufacturers of the Auto-Copyist copying apparatus?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Saw.**—W. W. (*Caverton*) writes, in reply to TOP SAWYER (see p. 478, No. 134):—"The wood spring for saw is about 8 ft. by 4 in. by 1¼ in., and should taper a little towards the point, and is fixed to the rafter in the manner shown in Fig. 1. As to support for upper end of saw G (see p. 347, No. 126), I am not able to give any stated length, for that all depends

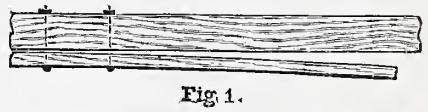


Fig. 1.

Fig. 2.

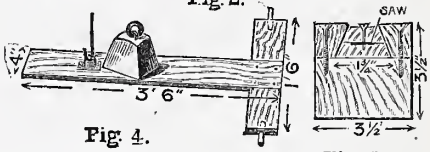

Fig. 4. Fig. 3.

Saw: Rafter, Treadle, Slide, etc.

on the height of your strap—mine is 9 ft. long, and 3½ in. by 2¾ in. thick, and is fixed to both upper and under rafters, and must be perfectly perpendicular and firm. The saw is 2 ft. long by ¾ in., and is mounted in slides as in Fig. 2; the slots the slides run in must be double their length—18 in. The weight on the treadle strains the saw, and makes it heavy and powerful, and is placed immediately behind the wire which connects the under slide and the treadle. But all the same, the wood spring must be able to pull both treadle weight and saw to the top for the workman to get the downward stroke. It should not fall too hard against the top—just nearly balanced, of course; that can be regulated by the weight being placed either backwards or forwards. The wood is all larch, except the sides, which are ash. All the iron about it are the upper and under wires, and the staples, which are fixed in a piece of plate iron, and then fixed on to the slides and treadle. The height of bench is 2 ft. 10 in. All the wood must be perfectly dry."

**Dovetailing.**—E. H. H. (*Chatham*) writes, in reply to L. E. W. (*Hutt*) on dovetailing (see p. 669, No. 93):—"I always cut the mortises first, and then

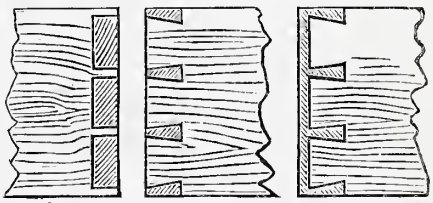

Fig. 1. Fig. 2.

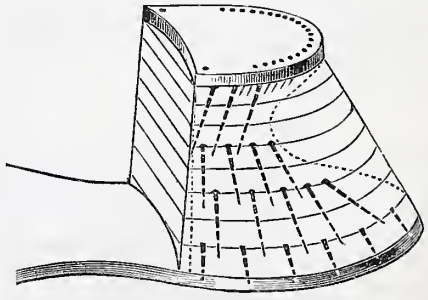
Dovetailing Examples.

place them in position on the end of front or back, and mark the lines in with the dovetail saw, and then cut slightly outside the lines so as to ensure a tight fit. L. E. W. would understand the work better if he got some of his joiner friends (I presume he has some) to show him, or by examining a drawer or box. Fig. 1 shows how two pieces of equal thickness are dovetailed together. Fig. 2 shows how drawer and box front are dovetailed together where it is desired to keep the end grain out of sight on one side or the face."

**Wurtemberg Heels.**—H. G. (*Bishopsgate*) writes, in reply to T. R. (*Ripon*) (see p. 747, Vol. I.):—"I send this sketch, which I think speaks for itself.



Wurtemberg Heel.

The dotted lines show where the leather is to be cut away. The heel when built should be placed against a straight bit of wood, and see that it is level with sole; if not, hammer the heel until it is."

**Fountain Driven by Engine.**—M. (*Bishop Auckland*) writes, in reply to C. A. P. (*Ealing*) (see p. 510, No. 136):—"You will require a force pump with an air vessel on the delivery pipe, and a very fine jet for the fountain. The pump will be worked by the engine. It should be a double-acting pump, or you might use two single-acting pumps. Without more particulars I cannot give you any sizes."

**Boiled or Unboiled Oil.**—G. P. (*Elgin*) writes, in reply to A WEEKLY SUBSCRIBER (see p. 454, No. 133):—He says he has WORK from the beginning; then let him look up 'House Painting' (Vol. I., p. 659); he will find there full information regarding the various oils used in painting. Again, on p. 125, Vol. III., of WORK, he will find a reply by F. P. to W. S. (*Inverness*); let him read this also. He will then have as full information as it is possible to give about the use of *raw* and of *boiled* linseed oil. It comes to this: both oils are glossy when applied in sufficient quantity; boiled linseed oil has more body and is more brilliant than raw linseed oil; raw linseed oil is lighter in colour, and is not so liable to blister as boiled linseed oil; boiled linseed oil dries quicker than raw linseed oil."

**Polishing Pebbles.**—T. F. (*London, S.W.*) writes:—"If SPES MEA (see p. 542, No. 138) will turn to Vol. VIII. of the *Boys' Own Paper*, he will there find not only full instructions as to the cutting of pebbles, but also instructions for polishing them after they are cut."

**Locks.**—W. L. (*Wolverhampton*) writes, in reply to J. G. (*Bloomsbury*) (see p. 478, No. 134):—"I beg to say that Mr. J. J. Wakeman, St. John's Square, Wolverhampton, is a good and cheap maker of letter locks. J. G. says he believes they are made 'somewhere abroad;' but I should certainly advise him to buy at home, as there is not a great demand for these things; moreover, the trouble and expense of getting them are considerable, and I doubt if J. G. would get any pecuniary advantage in the end. One thing he would get, and that is inferior workmanship. I have bought them for export for years, and had them made to foreign patterns; but I never yet bought a foreign make, and, what is more, I never intend. If J. G. prefers, I can give him the name of a foreign maker; but only if he *much* prefers it."

**To Preserve Stone.**—In reply to H. L. P. (*Montrose*) (see p. 526, No. 137), B. B. (*Deptford, S.E.*) writes:—"In answer to your query, I would recommend you to try Szerelmey Stone Liquid."

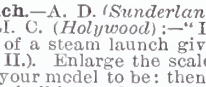
**Colouring Bright Steel Surfaces.**—LIFEBOAT writes, in reply to BARIUM (see p. 542, No. 138):—"Messrs. B. Newham, of Slude Lane, Sheffield, make a speciality of a spirit varnish suitable for this purpose, in gold, vermilion, and blue colours, for which they claim that it will not chip, and in the case of the blue, a deep, brilliant, and intense blue colour. They are made specially for edge toolmakers. Prices range from 8s. to 10s. per gallon for gold and blue to 16s. for vermilion, wholesale price-list; samples sent free. The intensity of the blue, and, I presume, the other colours, can be reduced by the addition of methylated spirits."

**Preserving Stone.**—M. (*Bishop Auckland*) writes, in reply to H. L. P. (*Montrose*) (see p. 526, No. 137):—"You can procure solutions for coating stone work, to preserve it from decay, from the Silicate Paint Company, Cannon Street, London; or from A. T. Morse & Co., Ward Road, High Street, Stratford; either of whom will give you all particulars respecting it."

**Waterproof Fluid Glue.**—THE WATERPROOF GLUE COMPANY write, in reply to LONDON (see p. 542, No. 138):—"Our glue can be obtained from Messrs. Moseley & Son, High Holborn, Messrs. Crowden & Garrod, or Messrs. W. B. Fordham and Sons, Ltd., London."

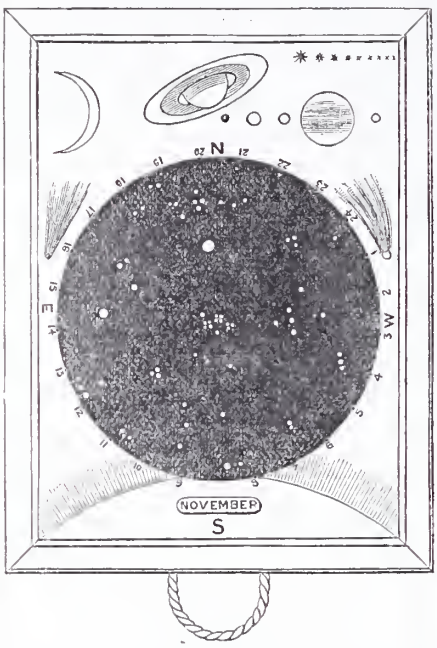
**Steam Launch.**—A. D. (*Sunderland*), writes, in answer to A. M. C. (*Holywood*):—"I should say, follow the plan of a steam launch given in No. 71 of WORK (Vol. II.). Enlarge the scale of it to the size you desire your model to be: then make a full-size model of the hull in wood, but do not hollow it out; then take two sheets of tin and block it on that pattern in two halves (starboard side and port side). Have the stern-post, keel, and stem of brass. I should advise it this shape:

and of one piece. Then solder your two sides on to it; bend some stout brass or other wire the shape of the sections given, and solder them in the inside. To take the place of frames in an iron ship, bend a long strip of tin, say ½ in. wide, at right angles, so:



and solder it round inside to form stringers to rest deck on. I leave the deck fittings and masts to A. M. C.'s judgment, and also the painting. A. M. C. can write to Stevens' Model Dockyard, 22, Aldgate, London, for illustrated catalogue, price 3d., and he can choose the engines he would like from it."

**Plan of the Heavens.**—F. H. (*Battersea*) writes, in reply to M. D. C. (*Liverpool*) (see p. 510, No. 136):—"I beg to offer my idea to utilise the plan of the heavens given with the first part of 'The Story of the Heavens.' Take two pieces of stout cardboard, 24 in. by 20 in.; on one piece paste the blue sheet, and when this is dry cut the circle out, allowing it to be ¾ in. larger than the blue centre. On the other sheet of cardboard draw a circle, the exact size of the ecliptic on the blue sheet, and let the line of the circle come within 2 in. of the bottom end of the cardboard. Divide this circle into twenty-four parts, cut out the circle, and also a small hole between the division at the bottom. These divisions are now numbered—mine is set for between eight and nine o'clock at night: that is to say, eight is marked on the right-hand side of the slot, and nine on the left, then ten, eleven, twelve, and so on round the ecliptic to the left. Around the blue sheet on the white margin, paste the names of the twelve months cut out of an old almanac, November at 24, December at 2, January at 4, and so on round the margin. At the back of the blue sheet, a small grooved wheel is glued in the centre. Around this wheel is an endless cord, reaching 3 in. below the outside of the blue sheet; through the centre of the blue sheet and wheel a hole is bored, to fasten it with screw or nail to the wall. The white sheet with ecliptic cut out is fastened over the blue sheet in such a manner that when the blue sheet is turned round, the name of the month can be seen through the slot at the bottom of the ecliptic. The best way



Plan of the Heavens.

to do this is to have the word August at the bottom, and adjust the opening to the circle of the ecliptic on the blue sheet. Before fixing, both sheets are sized, and varnished with spirit varnish. To use the star map, suppose you want to see what stars will be visible (on a clear night) on November 3, turn the blue map round with the cord until the word November is shown through the slot. The stars visible on the blue map will be the same as the heavens at about eight o'clock in the evening; if earlier, a little to the left; if later, a little to the right. The stars overhead are on the line bisected by the circle marked 60. The horizon is round the ecliptic, looking to the north at the top, to the south at the bottom, to the east or west at the side. I have suggested how some of the cuts given in the work may be utilised round the white sheet. The whole might be framed and glazed with a stout batten at the back for the blue sheet to work on, and a slot cut in the rabbet at the bottom for the cord. This frame then could be turned about, on its side looking to the west, or upside down for the north, and so on, which will be more convenient than if it be fixed to the wall."

**Glass Blowing.**—M. (*Bishop Auckland*) writes, in reply to SPES MEA (see p. 542, No. 138):—"You will require a Bunsen burner or blow-pipe, a bellows worked by the foot, two pieces of indiarubber tube to connect gas and air (these should have taps at one end to regulate the supply), a few files, some pieces of charcoal with conical ends for expanding tubes, some cotton wadding for annealing the articles, and a supply of glass tubes and rods: these are sold by wholesale chemists, but any local chemist would procure them. The bench or board at which you work should be covered with sheet iron."

### V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—BRASS; KILDON; S. T. (*Oughtibridge*); M. H. T. ## *SALE AND EXCHANGE.*

**Victor** Cycle Co., Grimsby, sell Mail-cart Wheels and Parts. [15 R

**Who's Lunt?**—Why, the Best Man for Joiners' Tools, of warranted quality. Send stamp for our Seventh Edition Reduced Price List.—LUNT, Tool Merchant, 297, Hackney Road, London, E. [13 R

**The Universal Amateur Exchange.**—Electrical, Optical, Mechanical, Chemical, Photographic, etc. Established 1862. Catalogues, 2d.—A. CAPLATZI, Cheniés Street, Bedford Square. [8 R

**Joiners' Tool List,** post free.—BOOTH BROTHERS Dublin. [21 R

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath. 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repousse Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). [1 S

**Six Large Comic Fretwork Designs,** 1s. 1d.; sample, 3½d. Forty Small Designs, 7d.; Sample Sheet of Six, 2½d. Eiffel Tower, 1s. 1d.; all free.—TAYLOR'S Fretworkeries, Blackpool. [25 R

**¼ h.-p. Horizontal Steam Engine,** as described in the pages of WORK by F. A. M. All the castings, forgings, and other materials required in the construction of these excellently designed Engines, may be had from H. MILNES, Ingleby Works, Bradford. Prices on application.

**Picture Moulds.**—15 to 25 per cent. saved. Send for wholesale list, one stamp.—DENT'S, Importers, Tamworth. [3 R

**The Buyers' Guide** to the best Books on Mechanical Subjects, with table of contents, price 6d. In cloth, 1s. 6d.—Published by BRITANNIA Co., Engineers, Colchester.

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of three thousand new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Machinery wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send two stamps for Register to Box 505, BRITANNIA TOOL FACTORY, Colchester.

**"Bird-stuffing,"** illustrated, 7d. Illustrated Catalogue Artificial Eyes, Tools, Apparatus, Requisites, etc., 2d. free.—Messrs. DAVIS, Taxidermists, Dartford.

**Inexpensive and Artistic Materials** for all classes of decorations. Send for detailed lists.—W. T. CRAIG, Wick.

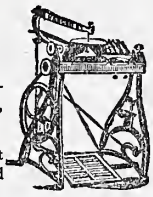
# FRETWORK AND CARVING.

*Highest Award—GOLD MEDAL.*

MACHINES, DESIGNS, TOOLS, WOOD, MIRRORS, HINGES, AND VARNISH, &c.

Fretwork Outfits, 1s. 4d., 2s. 6d., 3s. 6d., and 5s. 6d. each.

*Sets of Twelve Best Carving Tools, with Boxwood Handles, 10s. free.*



All Materials and Tools supplied for Fretwork, Carving, Picture Framing, Brass, Leather, and Burnt Wood Work.

Our Catalogue, acknowledged the most complete, with 1,000 Illustrations, and all Instructions, free for six stamps.

**HARGER BROS., Settle, Yorks.**

# Poker Work.

"VULCAN" Machines and Patent Points for this beautiful and decorative work to be obtained of all Fancy Goods Dealers and all Art Depôts, or direct from ABBOTT BROS., White Horse Buildings, 100, HIGH HOLBORN; or Southall.

(See Notice in "WORK," November 7.)

LEE'S ILLUSTRATED CATALOGUE OF SELECTED

## AMERICAN TOOLS and MACHINERY.

Screw Cutting and other Lathes, Chucks, Slide-rests, Lathe Dogs, Polishing Lathes, Drilling Machines, Drills, Parallel and Instantaneous Grip Vices, Screw Stocks, Taps and Dies, Saws, Wrenches, &c., &c., specially selected from the best American Manufacturers, therefore of the very highest quality, and at low prices. *Send for Illustrated Catalogue*, 150 *Illustrations, price 6d., post free.*

MODEL STEAM ENGINES, and Complete Sets of Castings of same, of every description, from the smallest to powerful Engines.

LEE'S ILLUSTRATED CATALOGUE.

New and Revised, Prices greatly Reduced. To Amateurs the most useful book extant, and largest and best Catalogue in the Trade. 64 pages, 110 Illustrations, price 6d., post free. Please state whether American Tool or Model Steam Engine Catalogue is required when ordering. ONLY ADDRESS— *76, 77, and 78a, HIGH HOLBORN, LONDON, W.C.*

Gateway entrance directly opposite the Inns of Court Hotel. Awarded Prize Medal International Inventions Exhibition, 1885. Please name this Paper when writing.

## DELICIOUS TEMPERANCE DRINKS.

MASON'S NON-INTOXICATING BEER. MASON'S WINE ESSENCES.

These Essences produce in a few minutes a delicious Temperance Wine or Cordial, Ginger, Orange, Raspberry, Black Currant, Lime Fruit, etc. One Tablespoonful of Mason's Extract of Herbs makes one gallon of Splendid Beer, refreshing and non-intoxicating.

A Sample Bottle of either Essence or Extract sent on receipt of 9 stamps, or a bottle of each for 15 stamps.

AGENTS WANTED.

**NEWBALL & MASON,**
*Nottingham.*

ESTABLISHED 1851.

## BIRKBECK BANK,

Southampton Buildings, Chancery Lane, London.

THREE per CENT. INTEREST allowed on DEPOSITS, repayable on demand.

TWO per CENT. INTEREST on CURRENT ACCOUNTS calculated on the minimum monthly balances, when not drawn below £100.

STOCKS, SHARES, and ANNUITIES Purchased and Sold.

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH or A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY, as above.

The BIRKBECK ALMANACK, with full particulars, post free on application. FRANCIS RAVENSCROFT, Manager.

## PAINTERS!! GRAINERS!! DECORATORS!!

**The Art of Graining** is now complete, and contains 20 splendid plates. The finest example of graining ever published. Each plate is 18 x 13.

*Price in Parts, 36s. Bound, 42s.*

30 pages of Technical Instruction.

**Painted Wall Decoration.**

*2/6* The Christmas Number of the Journal of Decorative Art. *2/6*

A Perfect Manual of Design and Technical Instruction on

SURFACE DECORATION,

containing

10 LARGE SHEETS OF WORKING DESIGNS, BORDERS, DIAPERS, POWDERINGS, ETC. ETC.

(*Price* **2s. 6d.**; *post free,* **2s. 9d.**)

*For full particulars, see the November Number of* The Journal of Decorative Art. (7d.)

W. G. SUTHERLAND,
15, ST. ANN STREET, MANCHESTER.

SIMPKIN, MARSHALL & CO., LTD.,
317, STRAND, LONDON.

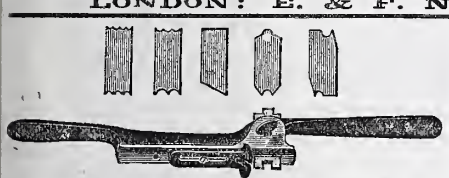
THIRD EDITION, with 1,420 Illustrations, 700 pages, demy 8vo, cloth, price 6s., post free.

## SPONS' MECHANICS' OWN BOOK.

A MANUAL FOR HANDICRAFTSMEN AND AMATEURS.

SUMMARY OF CONTENTS:—Casting and Founding in Iron, Brass, and Bronze—Forging and Finishing—Sheet Metal Working—Soldering and Brazing—Carpentry and Joinery: embracing descriptions of 400 Woods; over 200 Illustrations of Tools and their Uses; Explanations, with Diagrams, of 116 Joints and Hinges; and examples of Construction of Workshop Appliances, Rough Furniture, Garden Erections, and House Building—Cabinet Making and Veneering—Carving and Fretwork—Picture Frame Making—Upholstery—Painting, Graining, and Marbling—Varnishing, Polishing, and Gilding—Mechanical Movements, illustrating Contrivances for transmitting Motion—Turning in Wood and Metals—Masonry, Brickwork, and Concrete—Plastering, Whitewashing, and Paperhanging—Bells and Gas-fitting—Lighting, Warming, and Ventilating—Roads and Bridges—Ditches and Drains—Water Supply and Sanitation—House Construction in New Countries.

LONDON: E. & F. N. SPON, 125, STRAND.



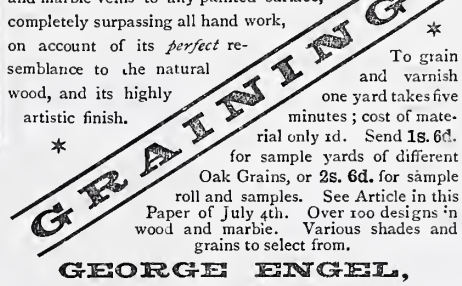
## NEW REGISTERED HAND BEADER,

With Six Irons, cutting Twelve different patterns in Reeds, Quirks, Rebates, Beader, Hollow Fancy Reeds. Length, 9½ in. Post free, 2s. 6d. Send for our 200-Page Catalogue, 700 Illustrations. By post, 6d.

**MOSELEY & SON, 323, High Holborn.**

## THE NEW PATENT TRANSFER GRAINING PAPER,

As its name implies, transfers natural wood and marble veins to any painted surface, completely surpassing all hand work, on account of its *perfect* resemblance to the natural wood, and its highly artistic finish.



To grain and varnish one yard takes five minutes; cost of material only 1d. Send 1s. 6d. for sample yards of different Oak Grains, or 2s. 6d. for sample roll and samples. See Article in this Paper of July 4th. Over 100 designs in wood and marble. Various shades and grains to select from.

**GEORGE ENGEL,**
18, CASTLE STREET, FALCON SQUARE, LONDON, E.C.

Use only the **PATENT Transfer Graining Paper.**

*BEWARE of useless, spurious imitations.*

## COMFORT WARMTH & HEALTH IN WINTER

FOR **3/11**

We will supply you a very good Unshrinkable Flannel Shirt in pretty Greys and Fawns that will wear twice the length of time of any other shirt. Send size of neckband to **West Riding Flannel Co., Leeds.** Carriage Paid on two or more shirts. Write for patterns.

## THE WORK DEPÔT.

**Irish Distressed Ladies' Fund, 17, North Audley Street, W.**

TROUSSEAUX—EMBROIDERY—SMOCKING—LAYETTES—HANDKERCHIEFS MARKED—FANCY WORK.

MISS LEAHY, Manageress.

EXTRACTS FROM LETTERS.

"I am delighted with the work, which I received to-day. The ——— are beautiful, and shall never go anywhere else for Lingerie. . . . I think the things are cheap."

"We are much pleased with the linen, and think it is *beautifully* worked."

"Miss ——— has received the handkerchiefs, and likes them very much."

"Mrs. ——— is much pleased with the frocks."

A Thrilling Christmas Novel.

## Clark Russell's New Novel,

entitled, "MRS. DINES' JEWELS," a Mid-Atlantic Romance, appears in "YULE TIDE," Cassell's Christmas Annual for 1891, price 1s.; post free, 1s. 3d.

## The Historical Picture of the Year

is "The Lady with the Lamp" (Miss Nightingale at Scutari, 1854), which is given away with "YULE TIDE," Cassell's Christmas Annual for 1891, price 1s.; post free, 1s. 3d.

THE FIRST NUMBER FOR THE NEW YEAR OF

## CASSELL'S SATURDAY JOURNAL

(No. 431, to be published on **Wednesday, December 30th, 1891**, price *1d.*) will contain the Opening Chapter of a New Serial, describing AN ACTUAL MODERN DETECTIVE EXPERIENCE, by a well-known CHIEF CONSTABLE, entitled "*A NOTEWORTHY CASE*," Illustrated by GORDON BROWNE. The same Number will also contain—

1. **A Thames Talisman.** A Complete Story by Major ARTHUR GRIFFITHS, Author of "Fast and Loose," etc.
2. **Monte Carlo and its Gaming Tables.** With Three Illustrations.
3. **Rural Couples at the Altar.** By A COUNTRY CLERGYMAN.
4. **Clementina: a Tragedy.** By G. B. BURGIN, Author of "A Quaker Girl," etc.
5. **Editors of To-Day:** Mr. F. C. BURNAND, Editor of *Punch*. With a Portrait by ALFRED BRYAN.
6. **Three Humorous Illustrations** by FREDERICK BARNARD and J. F. SULLIVAN.
7. **Eminent Men as Dispensers of Patronage.**
8. **An Excellent Knave.** By J. FITZGERALD MOLLOY.
9. **The Way Houses are Built for Nothing.**
10. **All for All.** Interesting and Entertaining Notes—personal, literary, artistic, scientific, domestic, anecdotal, and miscellaneous.
11. **How Novelists Kill their Villains.** By A NOVEL-DISSECTOR.
12. **Answers to Correspondents.** Legal, medical, domestic, and general information on topics of interest to all. Also Amusing and Entertaining Anecdotes, Poems, Sketches, Jokes and Jottings.

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## AUTOMATIC FOLDING SECRÉTAIRE FOR HOME OR OFFICE.

BY J. WHITFIELD HARLAND.

Economising Space and Time, and Attractive Appearance—How to Scheme Improvements—Methods of Assisting the Faculties—Occupation of Space by Movement of Parts otherwise Wasted—Actuating several Movements by the same Motion and Force—Conical Casters—Locking up Various Parts by a Single Motion of One Knob—Style of Design—The Main Construction—End Frames—Back Frame—Top—Bookcase above, if Preferred—Fittings in Carcase, the Movable Desk-Table and Slope, the Pigeon-Holes and Drawers—Frame of Drawers to act as Strut to Stiffen the Carcase—Front Hinged Desk-flap and Locking Apparatus—The Desk-Shutter—Under Portion—Doors and Drawer-Nests—How to fix Pivots—Connecting-Rods—Inner Plating with Steel—Converting Secrétaire into Fire- and Burglar-Proof Safe.

Having been consulted as to the best way of designing a secrétaire or writing-desk for office or home use, which should take up the least possible space consistent with utility, and at the same time form a decorative piece of furniture at a comparatively low price, and which should be capable of being instantly closed without disarrangement of papers, etc., I thought out and designed the automatic folding desk, of which the illustrations and the following constructive description may, I hope, be interesting to readers of Work.

The desiderata are to economise (1) space and (2) time, with an exterior sufficiently attractive in appearance. As to space, the ordinary office desk, with pigeon-holes, drawers, etc., with semi-circular shutter and nest of drawers at each side underneath, takes up about 4 ft. in length by 3 ft. or more in width or depth—*i.e.*, about 12 superficial feet. As to time, there are eight or ten drawers to lock up separately, besides closing and locking the desk itself. It will be noted that a space necessary for the legs and feet of a person using the desk—namely, the hollow under centre of desk—is always wasted, or, at most, is a receptacle for the "W. P. B."

When the desk is in use, we cannot dispense with room for the legs—say, 20 in. wide. The space is then necessary, but when not in use this space is useless—that is, it is simply wasted—and by the conditions, should be utilised when not in use, and still be available when required. I prefer to jot down the train of reasoning, that others may get an insight into the practical process of designing (or inventing, if preferred) means to an end expressed in the conditions which, technically, might have a greater value than the mere design now under consideration. Thousands who will never carry out the subject of this paper may deduce from it the way to carry out similar problems in other directions. Analogy and individual taste and requirements run on the lines suggested may result in improvements unforeseen to me, from other data, from other exigencies, and for indefinitely other objects; hence I prefer to show the brain action wanted, not merely for the present purpose, but for all other parallel or similar cases. In a few words, it is this: First examine thoroughly existing models; next criticise their shortcomings, and try to devise methods of utilising waste space, and to see if time be wasted in their use or not, and if so, to obviate the need for such waste of time as may exist.

Parenthetically, I have never seen mentioned in any text-book, or seen in practice, a valuable use of the hinge of the every-day "two-foot rule." I have a habit, when thinking out the three dimensions (length, breadth, and thickness), of playing with my rule-hinge to aid my imagination, and convey to "my mind's eye" an idea of relative proportion, putting my thumbs at certain points on each limb, and setting the joint at right angles. It may be put down as a foolish trick, but it does at times help the mind in its conceptions on every point, especially of leverage, change of position, etc., and saves making *model drawings*—that is, drawings where portions are cut out and are movable, in order to see where, in their orbit, they will clear other points of probable contact without clashing with other movable points at certain parts of their passage when in motion.

Returning to the means of economising the above-mentioned space: Let us suppose the usual nest of drawers on each side, which ordinarily support the desk, and are about 10 in. wide by 16 in. deep, and imagine them fixed to a door on hinges so that they could revolve into the space under the desk lengthwise across, thus occupying, including casing, only about 12 in. deep by 18 in. long, and partly utilising the 20 in. space between the nests when open. A glance at the plan (Fig. 1), which is divided so as to show position of one half open and the other half shut, and the front elevation (Fig. 3), similarly drawn, will show the working of the two nests of drawers on the pivots, *c*, *c*. Here the flap or door forming the side of the drawer casing (*c d* in plan) is, of course, made to extend to the centre line in each case, so as to fully close the aperture, whilst the casing (*a*, *b*, *c*, *e*) when swung open leaves 10 in. clear space on each side of centre line for the legs and feet of the writer using the desk. When closed (see end view, Fig. 4), the case with drawers folded inside measures only 1 ft. 4 in., and the desk above it 2 ft., or when open, 3 ft. 5 in., from back to front. The only motion required to open the secrétaire is to draw forward the desk-table, after unlocking, 12 in., which actuates two connecting-rods fixed by pivots at one end to the top of each drawer-nest, and at the other to the underside of the desk-table (see *f*, *g*, $g^2$ in Fig. 1). These rods being drawn forward 12 in.—*i.e.*, from *g* to $g^2$—cause the nests of drawers to turn on their hinges or pivots until they are at right angles to their former position, and face outwards. The same motion of the desk-table forward draws a cord fixed at *l* (Fig. 2) over the pulleys, *k*, *j*, and attached to the desk-shutter, *m i*, at *i*, and draws it back from *i* to *j*, thus fully opening it. The desk-flap, *m n*, with its covering moulding, hinged at *p*, can now be let down flat, giving 18 in. instead of 12 in. extra depth of desk space. It should be noted that the sides of desk and the drawers and pigeon-holes forming its interior fittings do not move—merely the table. By using spiral springs, the desk-shutter will close automatically when the desk-table is pushed back, and the flap turned upright to meet it. Conical casters are fixed to support the weight of the drawer-nests whilst revolving, so as to take the strain off the hinge pivots, and render the opening and shutting very easy.

It will be seen from the foregoing that one operation is all that is required to open or close the whole thing, and that therefore one lock is all that is necessary to secure the whole of the eight drawers, the desk itself, and its contents; and (as will be now described) this is a spring lock. By merely shutting up the desk, everything is locked up instantly. On referring to Fig. 3, the dotted lines on the desk-flap show the bolts for locking by means of a quarter turn of the handle or knob shown in half elevation, and a toothed wheel attached to the knob working into racks on the bolts, which also carry snugs to fit into the gudgeons fixed to the front bar of the desk-shutter.

To prevent unlocking, it is only necessary to lock the handle or knob so that it cannot turn. This is effected by having a spring bolt in the neck of the knob, which fits a hole in the plate through which it passes. In front of this spring bolt, and in the knob itself, is a five-lever lock—very small, of course, but inaccessible: the proper key alone being capable of drawing back, lever by lever, the stops and the spring bolt. The keyhole is shown in the front of the knob at *r* (Fig. 3), whilst at *s* is shown a stop which prevents the nests of drawers or the doors underneath from being opened so long as the desk is locked. If desired to be made extra secure, a lock can, of course, be also fitted to the stiles of the doors, but this is, in my opinion, unnecessary. A sliding shutter made in the knob to cover the keyhole could also be fitted, thus fully concealing the means of opening the lock. As there is no bottom, the whole thing should be fixed firmly to the floor, inside, with snugs and coach screws.

In order still further to save space, and to give the secrétaire a handsome look as a pieces of furniture, a bookcase could be fitted to part of the top, or it could be finished, where a bookcase is not desired, by a small balustrade and cap-mould, as shown in Fig. 4 in dotted line.

Having thus described the automatic working of the various parts, I will now give the main construction; but I do not give minute details, as it is unlikely that a tyro would undertake the making of so important a piece of furniture; whilst those amateurs who attempt it with any chance of success will have had the experience that will suggest these minor points. My design is semi-Gothic, but can be just as well carried out in Queen Anne or in Renaissance by modifying characteristics and mouldings. The construction in the main will be the same—viz., frame together the ends (see Fig. 4), consisting each of a long stile, A A, to finish 3 ft. 5 in. high, a short stile (front), B, to finish 2 ft. 4 in. high, two short and two longer rails, C, C, C, C, mortised and tenoned together, with a stile, E, and curved rail, D, to finish upper part. In drawing, the long stile, A, is cut narrower at upper part, to suit the narrower rails. The same width might be kept throughout to save trouble, if desired, but appearance is best consulted by reducing. The bottom stiles and rails are to finish 4 in. wide, the upper ones 3½ in. wide; all are 1¼ in. stuff, panelled with ¾ in. diagonal, jointed, stop-chamfered boarding well fitted into ½ in. grooves in framing, showing ⅜ in. reveal to face side, the framing stop-chamfered ¼ in. where shown, and having to front a carved bracket, G, 1 in. thick, centred and screwed and glued thereto, and finished with a moulding, F, and a plinth, H, as shown. On inner face, just behind and in line with the mould, F, a groove should be cut for the desk-table to slide in, and under it runners should also be fixed; another groove on inner face, curved to same radius as D, and straight along C, should be cut for the desk-shutter ends to work in. The upper end of the stile E, it should be noted, will tenon into a mortise in lower rail of the upper portion, which

involves driving the long stile on last, after fitting in all the panelling.

All the rails should be tenoned and wedged right through the long stile, which should be also rebated ½ in. each way inside to receive back frame, upon which a good deal of the rigidity of the casing depends, as there is neither bottom nor rail, and the top itself does not go across the full width. For this reason, at the foot of each stile an iron bracket of L shape should be screwed, to give fixing for coach screws, to the floor, and during its making a piece of stuff should be screwed to these brackets—at any rate, at the front—to hold it rigid.

When all this has been done, the back frame should next be made, and in order to give the rigidity just spoken of, should consist of two rails (top and bottom), with a centre stile or mounting—or even two, if preferred—tenoned and mortised into them; and these should be tenoned into mortises cut in each end stile right through them. The stiles and mountings should be 3 in. or 3½ in. wide by 1 in. thick, at least, rebated ½ in. by ½ in. to receive ½ in. matched boarding for filling of panels, which should be fitted, glued, and nailed to rebates from inner side. The stiles should also be rebated to fit rebates in the long stiles of ends, and should, when fixed in place, be glued to them and skew-nailed from within, and screwed in two or three holes to them from behind, and also from the ends under the plinth and under the mouldings, which afterwards conceal the screws.

The top should be of 1 in. stuff, 13 in. wide, either veneered or solid, and screwed down firmly at each end to the upper rails of the ends, and finished, front and ends, by a mitred moulding at edges; and if the bookcase is not desired, should have a thin narrow piece or strip laid upon it as a finish along ends and front to conceal the screws, forming a sort of ledge to carry balusters.

The casing, or carcase, being thus completed, the desk-table and flap should be made and fitted to slide freely in grooves cut in the ends to receive it. It should be framed of 1¼ in. stuff, with four transverse and two longitudinal pieces 3 in. wide, 3 ft. 10 in. long, exclusive of runners, and 1 ft. 9 in. wide. The two end panels should be filled in with ½ in. stuff in ½ in. rebates in the framing made to receive them, and finish flush with upper side. They will be 7 in. wide each and 1 ft. 3 in. long, leaving the centre panel 20 in. by 1 ft. 3 in., which is to be a loose desk-flap hinged to under side at front edge to the framing, so that it can be sloped as required for writing upon. This desk-flap should be clamped at ends, and be fitted into ½ in. rebate in the framing, so that it can lie flat therein when not required as a slope. If preferable, it might be framed and flush-panelled, and may be covered with cloth, leather, velvet, etc., glued down to its face, and finished according to taste; a 4 in. flap hinged to its back edge underneath would afford means for propping it up behind, the rebate being cut deeper, to allow of the flap folding down, as seen (*a b*, Fig. 2), so that it may slide under the pigeon-holes. There is an alternative which would save time in rapidly closing the desk—viz., that of leaving a 4 in. space in the pigeon-hole compartment, so that the flap could slide underneath whilst up. In the slope, holes for ink-wells and hollow for penholders, etc., could be made at the back. By this means the desk could be pushed back and closed without moving anything; or a fixed desk, the slope forming a lid, could be fitted to the sliding desk-table of the dimensions given—perhaps the best plan. The drawers and pigeon-holes in the desk portion should now be made, modified according to the above intentions.

As it is an object to obtain rigidity, the front framing of this portion—which, be it remembered, is immovable—should be strongly made and fitted tightly into the carcase, and well screwed thereto from inside, thus forming an extra rail across, and preventing end frames being forced either in or out, and keeping the grooves therein, in which slide the desk-table runners, close to their work. As no rail can be found room for below, owing to the folding of the drawers underneath, it is very important that this frame should be utilised in this manner—stiffening everything.

The desk flap (*n*, Fig. 2), which must not be confused with the slope and flap mentioned above, forms the front of the secrétaire when closed, and contains inside it the locking bars or bolts, carrying the knob with lock inside, or, if preferred, a lock of the usual kind, throwing a bolt into the knob spindle; and the tooth wheel that, actuated by the knob, throws the bolts should be made as follows (see Fig. 5, lettered to correspond with other Figs.).

The face of it should consist of a solid piece of stuff 3 ft. 10¼ in. long by 6 in. wide, ¾ in. thick, planed perfectly true and flat, upon which, on inner face, set out and fix the bolts and other parts of the locking arrangement, filling in with ½ in. stuff all the intermediate portions, which are shaded over in Fig. 5. This shading also shows the direction in which the grain of the wood should lie; which is important. This being done, and the working of the parts being ascertained to be perfect, the plate for the knob being screwed in its place, hinges fitted, and lock, if separate, fixed and found to act, the lining may be glued on. It should be of ⅜ in. stuff to finish out the total thickness to 1¾ in.—*i.e.*, same as the sliding desk-table. On its outer upper edge a small bead, *q*, should be planted for finish where the desk-shutter, *i m*, Fig. 2, joins it. At its lower edge a moulding, *o*, of the section shown should be planted, when rebated, partly on the face and partly on lower edge, which, when down, acts as a stop to the flap, and whilst up conceals the joining of the flap itself to the desk-table.

The only portion of the upper part of the secrétaire left to describe is the shutter, which, made in either of two ways, will complete this portion. In either case it consists of seven—or more, if preferred—strips of wood, hinged together, and chamfered or rounded off at edges, to permit of its following the curve like the well-known shop shutters.

It can be made of 1 in. stuff glued on to canvas at the back, as is often done, or, as I prefer, mortised through centrally in three places for bands of spring steel, ¾ in. wide by $\frac{1}{32}$ in. thick, to pass through; one mortise being central, the other two, say, about 6 in. from each end. For an extra strong job five steels might be used. As they require no fixing beyond being tightly drawn through the mortises, and turned over at each end and screwed, they could not so easily be broken into as if gluing on to canvas is resorted to. Clarke's patent shutter hinges could also be made available as an alternative. To the back of the last rib or lath should be attached the cord at *i*, passing over the pulleys fixed in the carcase, *j* and *k*, and the other extremity made fast to the desk-table at *l* (Fig. 2), which pulls the shutter up out of the way when the secrétaire is opened. To the first or front rib should be attached the catches into which the locking bolts of the front flap throw snugs to hold it down when closed.

I now come to the underneath portion of the construction. The sides of the nests of drawers, which form virtually a pair of doors, should be framed up of 1¼ in. stuff 4 in. wide, and panelled with ⅜ in. diagonal panelling, consisting of five 5 in. strips, all stop-chamfered ¼ in. as shown. These doors should be fitted exactly to close the aperture when shut—*i.e.*, each half of 3 ft. 10 in.—viz., 1 ft. 11 in. full. Into the hanging stiles of each (*c*, *c*) the back framing, *a*, *e*, of the drawer-nests should be dovetailed nearly through, and the front framing, *b*, *e*, should also be fixed to both top and bottom rails of these doors at 1 ft. 7 in. from back to front at *e*; the other side frames, *a*, *b*, being tenoned and mortised to the front and back frames. The drawers, runners, etc., can then be made and fitted. The doors, *c d*, *c d*, should not be hinged in the ordinary way, but hung on pivots at *c*, *c*, as shown, which consist of V fixings, like centre punches, working into plates having taper holes in them, so as to secure absolute accuracy of working as they move on their centres. A notch, *z*, must be cut for moulding, *o*, when flap is down. The exterior corners at *b*, *b*, can be rounded off so as not to remain sharp enough to bruise the knees or shins of the writer whilst seating himself or rising.

On the top edge of the back frames, *a c*, *a c*, at the points *f*, *f*, fix two pivots on which two connecting-rods, which may be of iron or brass, 13½ in. long, may work (see *f g*, *f g*), their centres being 12 in. apart. To ascertain the points *f* and *g*, you have only to lay the rod, *f g*, at an angle of 45°, and scribe on *f* the centre hole, and whilst the desk-table is closed, scribe on *g* the

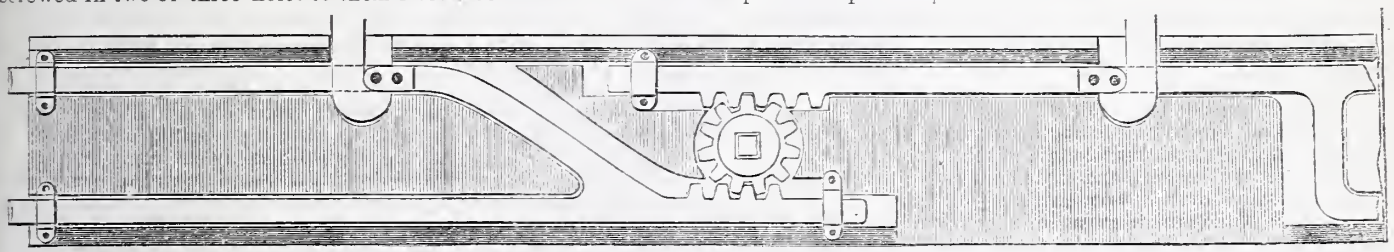

**Fig. 5.—Desk-Flap enlarged, showing Arrangement and Lock Bolts. (Scale, 2 in. to 1 ft.)**

centre hole, and when the pivots are in place and the desk is drawn out to its full extent, it will be found that the nest of drawers will swing exactly to its place square with the casing, and will allow the projecting part of each door beyond the drawer fronts (*c*, *d*) to act as a support for the desk front or flap to rest upon when down. To prevent the latter being scratched thereby, a piece of thin rubber may be nailed on the top of door at *d*. The doors should have a dumb plinth, as shown.

Should it be desirable to render this secrétaire more secure as a receptacle for valuable papers, etc., the whole of the inner surfaces of the carcase, doors, etc., may be lined with thin steel plates screwed to them, which would prevent their being cut through burglariously. It might also be made to act as a safe by being made of iron and steel throughout, intersected so as to break drills, etc., and made fireproof also. The exterior could be then enamelled to imitate wood of any preferred grain and colour to suit a library furniture—its instanter action rendering it valuable against sudden surprise when in use.

## HOW TO MOUNT CANVAS FOR PAINTINGS.

BY A. CONWAY.

ADVANTAGES OF MAKING FOR OWN USE — STRETCHERS — MATERIALS AND DIMENSIONS —FITTING OF JOINTS —WEDGES—COVERING —CANVAS—SUBSTITUTES.

I IMAGINE there are few readers for whom this article will have any attractions who need to be told that oil paintings are usually done on prepared canvas, and that this has to be stretched over a wooden frame or "stretcher." Still, there may be a good many who would willingly make their own stretchers and mount the canvas if they knew how. The work is simple enough, and they only want a few practical directions what to do and how to do it. Artists of the ordinary stamp are not above commercial considerations as to the cost of their materials, and to many of them the saving to be effected by doing what is suggested will not be unwelcome any more than to others. But perhaps this may seem false economy to some readers, for they may assume that the artist's time could be more remuneratively employed in painting than in making stretchers. Well, if an artist could always employ all his time profitably in painting, no doubt this might be the case, and those who can do so will, no doubt, prefer to get the canvas all ready to their hands. After all, though, the great majority have plenty of leisure—too much sometimes—and perhaps some may be glad to fill up their time profitably. Youngsters just beginning to paint may find every penny of consequence to them, and I hope the hints about to be given may be of use to them as well as to others. True, in London and many other places canvas all ready to work on can be had at such low prices that one wonders how it can be sold; but in many country districts it is by no means easy to get what is needed locally, and even when it is met with, the price is comparatively high. However, whether the user elects to make his own stretchers and mount the canvas on them or not, must be left to his own tastes. I can but direct him how to do what is necessary.

The stretchers or frames on which the canvas is to be mounted may as well first engage attention. Nothing need be said about their size, except that they may be anything. The construction is practically the same in all, with a slight addition, which will be named later on, for the largest sizes. These, however, the maker is not advised to begin with, as they may be too unwieldy. The material may be any kind of wood, though pine is generally used for the purpose, because it does as well as any of the more expensive kinds. In thickness it should be about 1 in.—that is, it is nominally of that thickness when in the rough, and before it is planed smooth. When this is done, it will seldom be more than ¾ in. thick, which is quite enough for small pictures, say, up to 30 in. by 20 in., and even for much larger sizes. If preferred, thicker wood may be used for all, but there is generally no object in doing so, and, of course, the greater the quantity used unnecessarily, the greater the amount of material wasted. The width of each piece may be from about 1 in. to 2½ in. or 3 in., according to size. The narrowest named is, however, only suitable for very small stretchers and for ordinary cabinet pictures. About 2 in. may be named as generally about the width which will be best.

Four pieces will be necessary for each stretcher—viz., two for the ends and two for

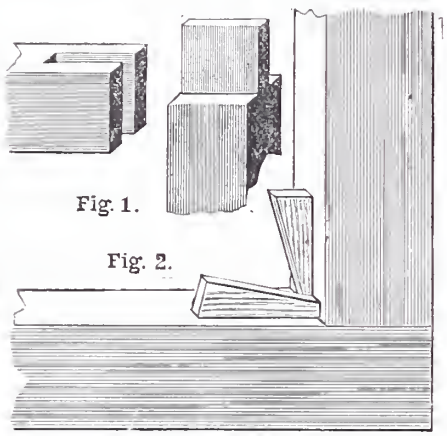

Fig. 1.

Fig. 2.

Fig. 1.—Mortise and Tenon Joint for Stretcher.
Fig. 2.—Cover of Stretcher with Wedges inserted.

the remainder. All must be cut of the full length required, and the ends be properly squared. They are fastened, or, rather, fitted together with a plain mortise and tenon joint, as shown in Fig. 1. Beyond saying that the tenon should be of about one-third the thickness of the stuff, it is unnecessary to make any remarks about this joint, as it is of the simplest kind. The parts should fit fairly well together, though the accuracy which would be expected in good cabinet work is not essential. In case of some workers not being quite so skilful as they might be, it may be desirable to remind them that the surfaces of the front—or that portion of the stretcher which is to be covered with canvas—must be level. The back is not so important, but if there is an inequality at the joiuts in front, it will make itself evident in the picture.

The stretcher might be covered with canvas now, but the wooden support would be rather a frame than a stretcher, for no provision has been made for "stretching" the canvas and taking up any slackness which may occur later on. The parts of the stretcher it must be understood, are only put together dry—*i.e.*, without glue and without any fastenings in the way of nails or pegs—so they can be pulled apart at auy time till bound over by the canvas. This being so, two wedges inserted in each corner, as in Fig. 2, afford a ready means of forcing the pieces of the frame somewhat apart, and in so doing, of course, tightening or stretching the canvas.

The wedges are usually of some hard wood about ⅛ in. thick, and for their reception spaces must be cut, one slightly prolonging the mortise, and the other alongside the tenon of the piece which fits to it.

The stretcher is, after the parts have been put together, ready for covering with the canvas. This should be cut at least sufficiently large to cover the edges of the stretcher, and if a little extra is allowed to lap over behind, so much the better. In doing this part of the work, a pair of the wide-jawed pincers as used by upholsterers will be found a convenience, but the ordinary kind may be used instead, or even they may be dispensed with, and the necessary pulling be done with the fingers. Whatever is used, care must be taken to get the canvas evenly stretched, so that puckers may be avoided. Evenness is even more essential at this stage than tightness, though this should be as great as convenient, otherwise, when the canvas becomes slack—as it probably will—there may be too much looseness to be taken up by the wedges. No specific directions need be given about the way to proceed in fastening the canvas, but probably the most satisfactory plan will be to fasten each edge down with one tack and then gradually work round. If this be carefully done, there is very slight risk of uneven stretching. The tacks are driven into the edge of the stretcher at intervals of, say, a couple of inches. The corners should be neatly folded over and each fastened with a tack. Any canvas projecting over the edge should either be neatly cut away or, better, be folded behind and tacked down there. The canvas should now be fairly tight—*i.e.*, presenting a flat surface sufficiently firm to be worked on. If it is not, or becomes slack, a tap or two on each wedge will make it as "tight as a drum," and nothing more is wanted. The whole of the work is much more easy, even to a novice, than it may seem to be from any description, and as "single-primed" canvas is purchasable at 4s. 6d. per yard 84 in. wide, it will be seen that the cost of canvases on stretchers need not be great when the amateur maker values his time—as he probably will—at *nil*. The addition referred to for large canvases is a cross-bar to keep the stretcher rigid, but will seldom be required.

Perhaps it may be well to say that canvas is to be had in various widths, and that unless some discretion is used in cutting it up, there may be more waste than is desirable or necessary. The prepared canvas is sold by the yard, and is obtainable at any good artists' colour shop. It may also be suggested that, in the absence of the real thing, various fabrics of similar substance may be used—coarse calico, holland, or anything of that kind. Something suitable can always be found in any country draper's shop, so that the would-be painter need never be at a loss in this respect. If he does not care to paint on the unprepared surface, he can easily prime it with some white paint thinned down with turps.

To show any painter-reader of WORK what apparently unpromising material can be used, I may say that I have an excellent picture by one of the ablest of the North Wales artists now living, painted on the back of a piece of glazed table baize. I may fittingly conclude the present paper by suggesting that this fact shows that it is the work, "layin' on the paint," and not the canvas, which makes a picture. Still, it

is not everyone who has the skill of the painter referred to, even among artists, and the beginner may as well use ordinary artists' canvas instead of some substitute for it. This brings to my recollection the saying that a "bad workman always finds fault with his tools," and the converse of this is equally true—namely, that a good workman will make a good job of whatever he takes in hand, even with poor appliances and unpromising material. That this is true is amply illustrated by the fact I have recorded above, in which a master of his art pressed into his service and made available for good work a piece of stuff which, in the hands of a less skilful artist, would have led to failure.

Fig. 1.

Fig. 1.—Single Bed. Fig. 2.—Double Bed.

## BEDSTEADS FOR EMERGENCIES AND FOLD-UP BATH.

BY JOHN CHARLES KING.

The handy man who made the Hat-rack described in No. 137 of Work, at the request of his friends at their stay in Paris during the Exhibition, 1889, was asked to knock up a bedstead or two for three friends who came in unexpectedly. Here we at once see the wide difference between an amateur who makes to conventional forms and fittings, and the man making one without having seen, heard, or thought of a ready knock-off bedstead, who on the instant evolves a new plan to meet means and requirements, using a chair for a bench, a camp-stool for a trestle, and some tools borrowed from a workman who was good enough to spare them for the novice.

Perhaps it was because he was not a bedstead maker or carpenter that his notions of work were untrammelled. "Bedsteads for three in an hour," was the laughing order of the young lady—his sister—though she little expected to see the order so promptly executed. They were done within two hours, and are still in use, as firm as when they were made.

The first one consisted of a square piece of deal, 2 in. by 2½ in., made up into a long frame, as shown by Fig. 1 (cheap and common deal). The open mortises were made by boring four holes 2½ in. from each end of the two long pieces; two saw-cuts into these holes made the mortises in very little more time than it takes to write about it.

The tenons on the two cross-pieces, forming the head and foot of the bedstead, were cut to suit the mortise notches. These tenons were about ⅞ in. thick, to stand the strain on them. Stout canvas was nailed on the top of the frame with large clout-headed nails. The canvas lapped over an inch at joints, held in the middle by a strong safety-pin. Two of these pieces are shown nailed on, to indicate the method. Screws secured the tenons in their mortises, which, when removed and the stiles taken out, allowed the canvas to be rolled round the long pieces for stowing away when not wanted.

A large camp-stool at head and foot served to support it, instead of legs. A mattress was not wanted; the canvas was sufficiently yielding. A little over half an hour was the time taken to make this single bed. The wood, canvas, screws, and nails cost 3s. 4d.

A double bedstead, on legs of some sort, was requested.

Lighter material was brought in for this one. Common deal, as for the single one, but only ⅝ in. thick board, served the purpose for all the parts—top, legs, and stays, or brace-pieces.

Fig. 2 is a double bedstead, made so as to take apart easily, so as to be carried on the arm in moving from the lodging.

The board was cut to the uniform width of 4 in.—the sides and mid-rib were 6 ft. 6 in. long; the head- and foot-boards 5 ft. long; the braces or side-pieces to support the legs 4 ft. long; the legs 2 ft. 3 in. long; the middle diagonal braces 6 ft. 6 in. long. An upright middle leg supported the mid-rib of the frame, and was fixed to the diagonal braces by their passing through a long notch in it. For the convenience of fixing the vertical toe- and head-boards to the horizontal ones, four sliding butts were used. These are marked at B B. This angle form of frame stiffened head and foot of bedstead. The mid-rib, A, was notched so as to clip the flat toe- and head-boards, and was secured by long screws at C, C. The legs were screwed to the vertical head- and toe-boards, and to the long sides of frame. The diagonal leg-braces were fixed to legs and sides of frame by screws, as marked at D, D, making them unyielding.

To prevent the canvas when weighted drawing in the sides of the frame, and bending down the mid-rib, the diagonal braces, F, F, were halved up under the side frames, with a shoulder to the edge of each, and screwed there as shown. These braces were screwed together at G, and notched through the lower part of the middle leg of the bedstead, and screwed to it. Canvas served for a mattress, as in the single bed, the joints overlapping, and held by safety-pins.

It was easily taken apart, and occupied but little space when rolled up in the canvas. It is still in use in Paris, and likely to be for many years as an extra makeshift bedstead for two. The wood, canvas, screws, butts, and nails cost only 6s. 8d., and the time to complete it—an hour and a half.

The sanitary necessity called for a bath, and it was as quickly made up, though there was less of the makeshift and contrivance about it than the bedsteads, but the same aim was in view—economy of time and cost in making, and portability and packability, so as to occupy little space when folded-up—an essential thing in the rooms of a Parisian dwelling.

Some good yellow deal board, ⅝ in. thick, was bought and ripped into 3½ in. stuff, 740 ft. run. This was enough for the frame of a bath—50 in. long, 30 in. wide, and 30 in. deep.

It is made up in four parts—the sides and the ends separate, as shown by A and B, Fig. 3. The top and bottom of sides were screwed on to the uprights without lapping the joints. The ends had uprights screwed on to the top and bottom pieces, as shown in the sketch. These ends had cross-braces, shown at C C, screwed at the joints to the uprights.

This stuff had to be planed smooth, and all the edges well rounded off on the outsides and top inside edges, where the canvas was drawn over the edges or came in contact with them. For fixing the ends on to the sides to make a bath parallelogram shape, eight 2 in. brass sliding butts were used, one of which is shown at Fig. 4, and are shown fixed at J J J J, Fig. 3. These lock the ends to the sides immovably, yet are lifted apart and put together so easily.

The canvas was the stout sort used for fire-buckets. The dotted line shows the two ends and the bottom in one piece of canvas, into which the sides had to be sewn with a double-handed stitch of waxed threads, a thin ribbon of gutta-percha, ½ in. wide, laid between making a thoroughly water-tight joint, even for indifferent sewing, which was candidly admitted by the needleman. The top edges of the canvas had twenty-four button-holes worked in the canvas folded double. These took hold of twenty-four extra stout brass round-headed screws fixed in the upper part of the bath frame, as shown.

The canvas of the bath rested on the floor, so that to soften the resting-places for bathers a roll of carpet or wrappers laid down adds to the bather's comfort.

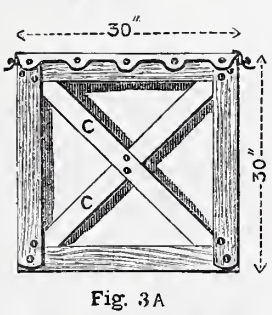

Fig. 3A

Fig. 5.

Fig 4

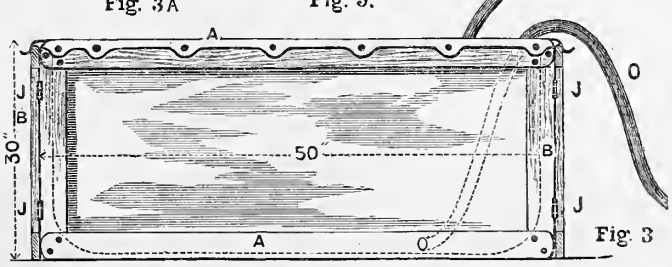

Fig. 3

Fig. 3.—Folding Bath: Side Elevation. Fig. 3 A.—Ditto: End Elevation. Fig. 4.—Butt Hinge Connection. Fig. 5.—Bath Complete: Folded.

Paris houses are mostly well supplied with water-taps, for supply by hose, if necessary; and for emptying the bath a flexible hose, with a low outfall, would act as a syphon, as it did with this bath. These are shown in the drawing of the bath.

To keep the bath sweet and clean, it must be wiped out well, and be dried before it is folded up and put away in an airy cupboard, or any odd corner of the room.

Instead of plain canvas, indiarubber dressed canvas might be used, and would be quickly cleaned and dried—the edges of lap-joints being cemented instead of being sewn together. The bath-frame is shown folded up in Fig. 5.

In the absence of fire-bucket canvas, closely woven canvas, dressed well with hot boiled linseed oil, and dried before making up, makes it waterproof, and answers the purpose.

What was serviceable in an emergency in Paris might be usefully so in England, in dwellings where room-space is contracted. The contrivances to supply the place of the real articles are certainly ingenious, and show considerable readiness of inventive power. There are not many, probably, who would have exhibited the same aptness in dealing with difficulties, and met so quickly and promptly the imperative call for beds and bath.

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

### The Feed-Pump and Governor.

An Injector—Considerations Affecting Capacity of Pump—Making the Pump Eccentric, Plunger, and Rod—Chucking and Boring Pump Body—Making and Grinding in Valves.

We have now completed the most important parts of the engine, and we might stop here, simply connecting the steam-pipe with the boiler, and conducting the exhaust steam away by another pipe. Our engine would, however, be deficient in two respects: it would have to be regulated as to its speed by hand, and it would possess no pump for supplying to its boiler the feed-water necessary to make up for what is boiled away. Of course, if steam is obtainable from the boiler of another engine, or if it be preferred to employ an injector to supply the boiler with water, no feed-pump would be necessary. I will tell my readers where they can obtain a small and very simple injector, suitable for supplying our engine boiler, in case they should prefer it, and will then describe the force-pump designed for this engine. A small injector can be obtained from Mr. E. Powell, of 12, Grove Hill Road, Tunbridge Wells. No. 1 size will supply a one or two horse-power boiler; it is quite a little thing, and very simple, having no adjustment, but only requiring the steam and water turned on: it costs £1 1s. I have seen one of them at work, and believe that though so small they are quite reliable.

As to the capacity required for our pump, if we relied on theory alone we might turn to a table showing the comparative volumes of water and steam at 40 lbs. pressure per square inch, when we should find that one cubic inch of water would give about 500 cubic inches of steam at 37 lbs. pressure above the atmosphere, and we might proceed to argue from this that, as the pump, being single acting, throws one barrel full to every two cylinders full of steam, therefore the pump would require to have a capacity of $\frac{1}{250}$ part of the cylinder. Suppose the steam cut off at $\frac{3}{4}$ of the stroke, then we have a length of 6 in. of the cylinder filled with steam for the double stroke, or one complete revolution; add another inch for leakage and call it 7 in.: now, the area of 2 in. being 3·14 square in., 7 in. by 3·14 in. gives 22 cubic in. of steam expended for each revolution. Our pump has a diameter of $\frac{1}{2}$ in. and a stroke of $\frac{3}{4}$ in., its area being ·2 square in.; ·2 in. by ·75 in. gives for the cubic in. of water thrown per revolution ·15. No pump will throw its full capacity, so we will only reckon on $\frac{2}{3}$ of this, and call the quantity of water delivered by the feed-pump per revolution ·1, or $\frac{1}{10}$ of a cubic in.: $\frac{1}{250}$ of the capacity of the cylinder; the actual amount thrown by the feed-pump, therefore, should be greater than what is theoretically required by as much as $\frac{1}{250}$ is greater than $\frac{1}{250}$.

This will perhaps be the place to explain that it is convenient to be able to regulate the amount of water thrown by the pump so as to balance as nearly as possible the quantity extracted from the boiler by evaporation. This is done in a very simple way by means of a "return cock," which is either fitted as a branch on to the delivery-pipe, or else is screwed into that part of the valve-box of the pump from which the delivery-pipe springs. By looking at the back view (Fig. 6, page 328), such a cock will be seen; it serves a double purpose; acting as a pet-cock, it will release any air that may have accumulated, and, by gradually adjusting it, it can be made to let out and allow to return to the supply tank any quantity of water forced by the pump and not required by the boiler. It is also convenient to have a pump of a little more than the size absolutely needed, because, when about to stop work—at dinner-time, for instance—we can, by filling up the boiler, both ensure its safety from burning while we are away, and also lower the pressure by the introduction of a considerable quantity of feed-water. These practical considerations make it desirable to have a pump of more than the theoretical capacity. Some, too, prefer to have both the pump and the injector, as they are sure then to have one available; also the injector can be used when the engine is standing still, provided only there is steam in the boiler, so that it could be used to fill up the boiler during the stoppage for meals.

Having now taken a little rest from the details of construction, let me direct my readers' attention to Figs. 4. 5 (page 260), where the pump appears in section and plan; also to Fig. 6 for end view, and to Figs. 20, 21, 22 (page 328) for the eccentric, plunger, and rod. A second pair of straps will be required exactly the same as those before described; when these are finished, the eccentric (Fig. 20) would be undertaken; the two holes for the screws may be bored first of all, and through these holes wood screws may be passed into C, Fig. 56 (page 581), which can then be adjusted upon B, so as to bring true first the hole to be bored, so as to fit upon the boss of the main eccentric; and then the outer rim to fit the strap; also, if the screw-holes are countersunk and the heads of the two screws do not project, the face of the eccentric can be turned; if not, a narrow band only can be turned round the edge, and the remainder might be finished by the file: then the other side would be either turned up flat or filed. Notice, however, that the eccentricity is in this case only $\frac{3}{8}$ in., and not $\frac{1}{2}$ in., as in the valve eccentric. We now pass on to the plunger and rod, about which there is little to say, except that the small end of the rod containing the hole for the pin should be case-hardened, and the pin itself must be of hard steel, and driven firmly into the eye of the brass plunger. The plunger itself is made in two pieces, for which castings are supplied, and the two parts are to be soldered together when the joint has been fitted, and cannot then be separated without unsoldering again; this, however, will most likely never be required.

Turning now to the pump itself, the casting for the body has on it a foot, or flange, best seen in Fig. 6, by which we may chuck it on the angle-plate on the face-plate chuck. This foot must first be brought flat and vertical, so as to be parallel with the centre line in Fig. 6, in such a way that, when standing on its flange upon the face-plate, the scriber point will come to the centre of the four holes—namely, the suction, the delivery, the top of the valve-box, and the barrel. To ascertain these centres, plug them up temporarily with wood, file off the wood level, and find the centre with the dividers. There should have been a facing on the bed against which the pump flange would have bolted, but none was made because some might not wish to have the pump at all, and the flange can be well enough fitted to the casting by rubbing the place where it is to go with red marking to try the flange upon it. First, however, we must have the flange upright, and not slanting, as it appears in Fig. 6; also it must be brought into a plane parallel with that in which the centre lines of the pump lie, as before described; when this is done, it can be clamped upon the angle-plate, and each of the three centre lines can be brought true with the centre of revolution one after the other. Let us begin with the longest part—the valve-box. Set this carefully true in the lathe by adjusting the flange upon the angle-plate, and clamp it firmly; then bore out the inside to $\frac{13}{16}$ in., $\frac{1}{2}$ in., and $\frac{5}{16}$ in., taking care to bring the valve-seats perfectly true and smooth; cut the thread for the cap that closes the top, and turn the mouth of the hole true; we might, if we wished, turn the outside as far as the delivery branch, but that would involve getting up the whole of the outside bright, and it may as well be painted. Now take off the face-plate chuck without disturbing the setting of the pump body, and turn the two small conical valves. These valves are made from two little castings. Taking the large one first, centre it, and bore the little hole up the wings, which receives the reduced spindle of the lower valve; countersink this hole slightly, put the carrier on the small end, and put the little casting between the centres; or it might be grasped at the small end by a universal chuck, and supported at the other by the back centre point in the drilled hole; turn it up, bringing the three flat wings to fit into the bored part of the valve-box, and bringing the part that fits the seating to exactly the same cone, rubbing red marking on the turned seat, and trying the valve in till it fits; then see that the largest part of the valve does not exceed $\frac{3}{8}$ in. diameter, so that there may be room for the water to pass. The smaller valve is to be turned in a similar way; the top of its spindle is to go into the hole in the upper valve to steady it, but it should not fit that hole closely. The small valve should be capable of lifting $\frac{1}{16}$ in., an amount which can be regulated by holding down the upper valve and lifting the lower one with a bit of wire; put up the suction, and file off the top of the spindle till the lift is correct.

Having turned the valves, put on the face-plate chuck with the pump body upon it; make a handle for the valves by boring a hole in the end of a bit of wood, into which you can drive the small end of the spindle; then, while the pump is going round and back in the lathe (for you must not let the lathe wheel go continuously), you proceed to grind the valves to their seats. Do not try to do this with emery—never try to grind brass with emery; you can do it with some of the grit from the grindstone trough, or, better still, with a little bit of oilstone crushed up with the hammer on any hard surface, because then you get it pure. The great danger to be guarded against in grinding in valves, or plugs, is lest you get the surfaces which ought to be water-tight scored in rings and rough. This may arise through not keeping the grinding material distributed; it won't do to use force or to keep grinding on; press very lightly and withdraw constantly, to pass the finger over the surface and re-distribute the powder, and continue till you see that smooth, dull look that appears on the plug of a gas-tap if you take it out. Water will do well enough to mix with the grinding powder; you and I, reader, will not imitate those who use the product of the salivary glands, though it may be so conveniently near at hand.

The two valves being ground to their seats so that air cannot be sucked through, we may turn the pump body round on the angle-plate and set the barrel true to bore it out to fit the plunger, and cut the thread for the gland; then turn it round again, and screw and face up the delivery branch. The pump is to be strongly bolted to the bed, and the studs should fit well into the holes in the flange, that it may not move. An india-rubber pipe is to be stretched over the bottom of the valve-box for the suction. The delivery-pipe has a small ring brazed to it after the union-nut is put over it; the nut holds the pipe by this ring, and clasps it up to the face of the delivery branch. Between the two faces would be interposed a ring of indiarubber to make the joint good. The return-cock already referred to, as seen in Fig. 6, is supposed to be screwed into the valve-box, but it need not be placed there: it might be fixed as a branch downwards from the delivery-pipe.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Setting Out, involving the Use of the Square and Gauges.

We made the acquaintance of the mortise gauge in our last lesson, marking by its aid the position of the mortise and the position and thickness of the tenon. The square is needed to mark the shoulders and set out the mortise. It is important to remember that the square should always be used from the same edge and side, *unless* the wood has been prepared perfectly parallel in width and thickness, in which case it is immaterial to which side it is applied. It is for this reason, among others, that workmen always mark the prepared side and edge of all work requiring setting out. Whenever setting out anything in pairs, be sure to keep each pair face to face, or mistakes will occur. It is frequently a great advantage to fix, with a hand-screw, all the stiles—mortised members—of a job together, when the setting out can be done on the edges of each, transferring the marks as necessary to the other edge with square; in doing so, care is needed to have all the inner edges together, as well as all pairs face to face.

The gauging must also be done from the same surfaces throughout the job—that is, the marked surface of each piece—in order that the work may be "flush," or even, when put together.

If you have to buy a square be sure to look at several, and make sure of getting a good one by getting one that agrees with two that mutually agree. Formerly, buying a square was more uncertain than now, but sometimes squares (so called) belie their name. I found no difficulty, however, in getting several for a class, some time ago, all alike and correct.

If a square is, or has become, incorrect it will give different indications when reversed, but do not venture to alter a square unless you are certain that the edge by which you are testing it is accurately straight, and not then unless you have had much experience.

Supposing the work is dovetailed the setting out is different, inasmuch as the *ends* of the wood are more important, and are usually gauged from. As the lines cross the fibre of the wood a cutting gauge is preferable to a marking gauge. It is to be set, for plain dovetails, fully the thickness of the wood, so that the pins will just project a shaving when the work is finished.

This gauging pre-supposes that the ends of the work are planed accurately; this of itself constitutes a difficult lesson to be mastered, though one in which my writing without your perseverance will be of no assistance. If the work is of equal thickness, then one setting of the gauge will suffice; if not, it is better to have two separate gauges than to risk mistakes.

Opinions differ as to the best procedure in dovetailing. This is as it should be, for do not circumstances alter cases? In the great majority of instances the dovetails may be cut first, because then they can be cut in pairs, which if the pins were cut first could not be the case, though there are sometimes circumstances which make it almost imperative to depart from the usual mode of procedure.

There are, of course, several other methods of joining, the setting out of some of which shall be described in the next paper.

## MEANS, MODES, AND METHODS.

### What to do with Empty Tins.

Nowadays that so many different articles are packed in tins, it is a puzzle to many people to know what to do with them when their contents have been used, and in consequence many useful tins find their way to the ashpit.

I make it a maxim to never throw away an empty tin. Cocoa and mustard tins, if in good order and with the covers, I reserve for holding nails, screws, etc.; it is much more convenient to keep them assorted in tins than knocking about in a box. All my dry paints, plaster of Paris, and such like, I keep in square tins, and by this plan none of my colours ever get spoiled by damp, besides being to hand whenever I want them.

Large fruit tins, empty tea canisters, and all large tins, if a little battered, I hold over a hot fire—not with the fingers, mind, but with a pair of tongs—until the solder melts and the sheets of tin fall asunder. When cool, I hammer out flat with a mallet on a block of wood and put by for future use. These are but a few of the ways in which old tins may be utilised, but to an inventive mind no doubt many other means of utilising them will crop up, and what was formerly regarded as waste become useful, if not ornamental.

### How to Mend a Broken Violin Bow.

A musical friend of mine came to me one day some time ago in great tribulation. He had broken his violin bow across the middle—the result of a fall—and not being able to tackle it himself, he begged me to try my hand at it. At first I was afraid it was

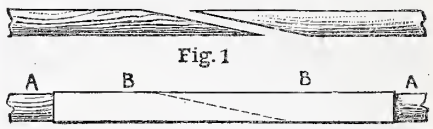

Fig. 1

Fig. 2.

Fig. 1.—How to cut Broken Ends to form Splice. Fig. 2.—Join Complete—A, Wood; B, Tubing.

done for, but after a little cogitation I hit on a plan which was very successful. The break was not straight across, but a little slanting, and with a sharp penknife I cut both ends so as to form a half-lap joint like Fig. 1. Then I got a nice piece of nickel-plated tubing—part of a pocket pencil, in fact—about four inches long, and which fitted tightly on the bow. I glued both bevels, and, about two inches above each, slipped the tubing over one half and then slipped in the other end, pressed well together, and left to dry. Fig. 2 shows join complete. It was a very good job, and stood well, the bow being in use still, and giving every satisfaction; the only fault being that it is a little heavy on account of the piece of tubing, which should be as light as possible.

### A Good Temporary Bench-Stop.

Many carpenters, when in want of a stop for temporary use—as, for instance, when working away from home—simply drive a few nails into the bench end, leaving the

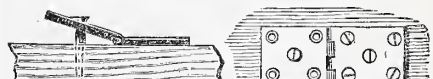

Fig. 1.—Stop ready for Use. Fig. 2.—Plan.

heads projecting enough to hold the wood. This is a bad plan, and a much better substitute can be made out of an ordinary butt hinge, one end of which should be filed into teeth so as to hold the wood better. This end should be left loose, and the other side screwed down tightly to the bench end. A long, light screw through the middle hole in the loose side will afford sufficient adjustment for thin or thick stuff. Figs. 1 and 2 will explain what I mean; it is much better than nails, and can be taken up when done with, and put away.

E. A. P.

*** This department of Work is open to the contributions of all who may be able to suggest some mode of procedure in working that he has tried himself and which may be useful to others. Considering the thousands of readers into whose hands Work goes weekly, there should be at least a column weekly, if not more, of such suggestions, etc.—Ed.

## AN AMATEUR'S READING-STAND, OR BOOK-REST.

BY F. B.

Being a tradesman, my time is broken up and into very much, and frequently when reading I am called away, and have to put my book down hurriedly. On coming back, I generally have a difficulty in finding the place.

However, I happened to have some disused brass gas-arms lying in a cupboard, and seeing these one day by mere chance, I thought of a way to make a book-rest out of them. What I thought of is shown by the drawings that accompany this paper.

It will be seen by Fig. 1 that it is well suited for reading, as it is adjustable to any height, by simply sliding arm up or down the standard. It also swings either way: which is very convenient, saving the trouble of lifting the whole concern when one wishes to get up from the chair.

Fig. 4.—Small Tray for Invalids.

I have sketched it from the back, because the different parts are seen better in that position. The parts lettered A, B, C, Fig. 1, and their accompanying joints, simply screw into each other; D was a socket which received a tapering joint. This I had to file to fit B. I next sawed 1½ in. off a 1 in. pipe, and then divided it again lengthwise, as seen in Fig. 3 at E, E. I then purchased a 1¼ in. brass hinge, D, which I soldered inside.

When I had got thus far, I thought I might as well make the book-rest so that it would take off and on—so that, if I wished to read at the table, I could do so (see Fig. 2). I cut two parallel cuts with an old tenon saw, to receive the ends of slot (A, Fig. 3), which I bent up out of a strip of brass, and fixed with solder from inside. I next took an old binding-screw from an electric battery, sawed the ends off, and drilled one so that the screw would not bite, leaving the other thread intact. These I fixed one on each half of tube, as shown at B, Fig. 3. I then cut two pieces of rubber sheeting, and fixed inside with glue. I also cut furrows lengthways, so that it would grip arm better (see C, Fig. 3). When this little contrivance is put on to the arm (C, Fig. 1), and screwed up tight, it may be raised or lowered to any angle required, without fear of slipping or altering its position, not even with a heavy book resting upon the book-rest.

I purchased next a plain band of brass, 3 in. wide by 2 ft. 3 in. long, and $\frac{1}{16}$ in. thick. This I cut into strips, ¾ in. wide, with a pair of snips. This gave me four lengths. I cut three of these again into shorter lengths, of 13 in. and 11½ in. full, so as to allow for working up into shape (see Fig. 2). I hammered them as flat as I could, and then filed them with a very fine flat file, finishing with two or three different sizes of emery-cloth.

My next difficulty was to drill the holes true, so that I could rivet them together, as shown in Fig. 2. I hit upon the plan of folding a piece of stout zinc round the end of one of these bands, so that it would slide off with a little pressure. I then drilled a small hole through both zinc and brass, and by this means I was able to measure accurately all the end holes; then, with a very little trouble, I was able to drill the others. I made my rivets out of brass wire. I next purchased a ½ in. hinge, for the back support, as shown at A, Fig. 2.

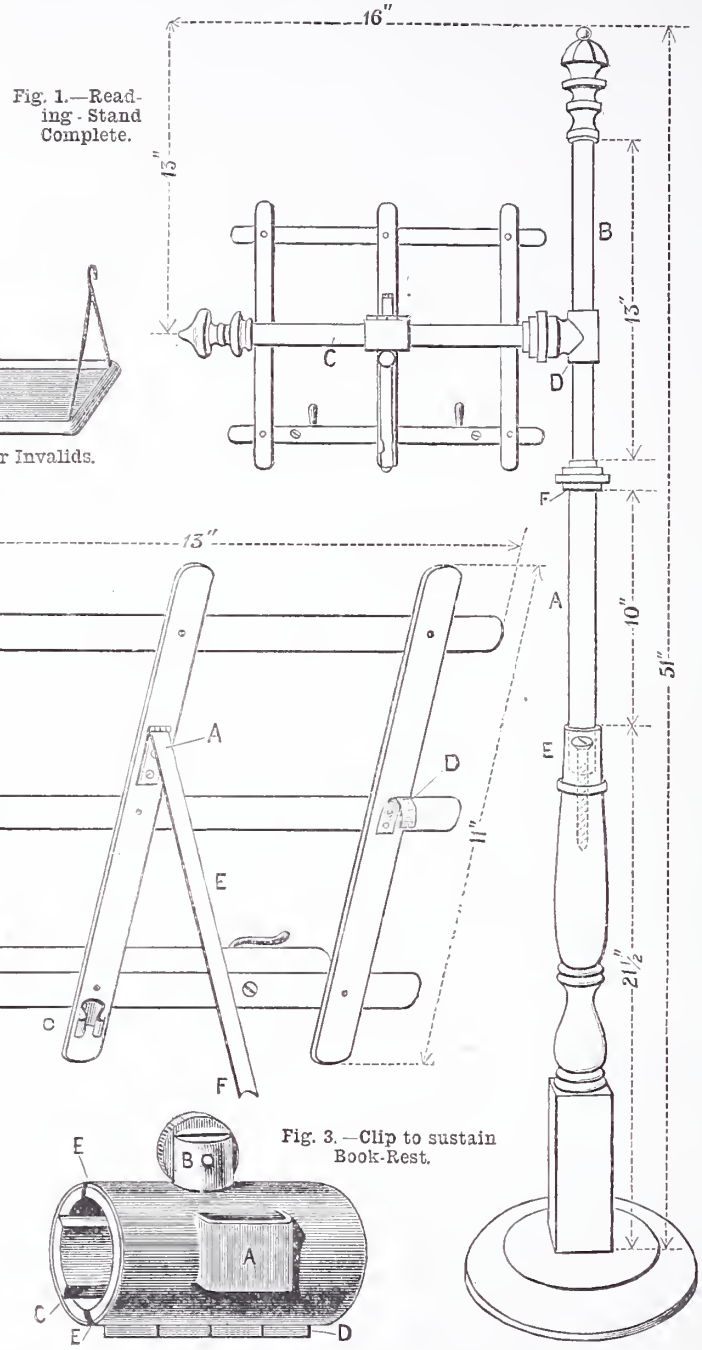

Fig. 1.—Reading-Stand Complete.

Fig. 2.—Book-Rest.

Fig. 3.—Clip to sustain Book-Rest.

My next job was to cut a piece of mahogany, to form a shelf to rest book on, 1¼ in. wide, 11½ in. long, and ⅜ in. thick. This was already polished. I fixed this on from back with screws, as shown at B, Fig. 2. I purchased hooks, for keeping the leaves of book down, at a piano maker's; but he charged so much, that if I had occasion to make another book-rest I should try my hand at making them out of an ordinary wood screw and a flat piece of brass filed into shape. I also found it necessary to make a small clip (see C, Fig. 2). This I made out of a thin strip of brass, and soldered it to centre-band, as shown. This tended to keep book-rest steady when fixed into its place. I also fixed two flat hooks, as shown at D, D, Fig. 2. This also I found an improvement in the same direction. The back support (E, Fig. 2) I made from strip of brass, ½ in. wide, and 7½ in. long, the end being filed with round file, to prevent it slipping when standing on the table (see F, Fig. 2).

Now we come to the lower portions. I had made up my mind that I should have to turn up a pedestal in lathe; but finding the leg of a common toilet table, I enlisted it into my service. The first thing was to turn it upside down, and bore a hole with centre-bit (see E, Fig. 1) 2½ in. deep, and just slightly larger than tubing, A, which it was to receive. I then took a 4 in. wood screw, and drove it in about half its length in centre of hole E: for what purpose I will explain presently.

My next difficulty was to get a base that would stand firm, and not be much in the way. This troubled me not a little, until I happened to see an old rusty tin plate, which suggested to me the plan I will now describe.

I put the plate on the fire with all the scraps of old lead pipe I could find, but I could not find enough to fill it, so I pressed a horse-shoe, a few old iron hooks, and a ½ lb. weight into my service. I was careful to put these near the edge of plate, so as to leave centre of it filled with lead. The plate measured 9 in. over all. I next proceeded to fix my plate (bottom upwards, of course) on the square end of the pedestal, taking care to have it in centre. I used a 5 in. wood screw and a washer for this purpose, and one or two nails to keep pedestal from twisting. I next cut a circular piece of wood the same size as plate. This I screwed to the bottom, after having first completed filling the plate with plaster of Paris.

There only remained to make the joint good between brass tubing, A, and the wooden pedestal at E. This I did by simply unscrewing tubing at F, Fig. 1, and placing A in position, taking great care to have it

upright. I then poured melted resin into the tube A, which flowed all round the wood screw, and filled up the space between wood and brass, making a clean and rigid joint with a very little trouble.

And that is how I made my book-rest, or music-stand. We use it also for a fire-screen, which is easily and effectively done by hanging a fancy worked banneret from the projecting arm. It is also very useful in a sick room, as the arm can be put to its full height, and a small tray suspended in front of patient (see Fig. 4). I ought to say I ebonised the wood and base, which makes a very good finish, and contrasts well with the brass-work.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

THE STUDY: THE WALLS—THE DADO—THE FRIEZE—ORNAMENTATION OF THE FLOOR—THE DOORS—SOME PRACTICAL SUGGESTIONS.

*The Study: the Walls.*—It will be remembered that I found the walls of my study covered with bare whitewash only from floor to ceiling; they were wholly innocent of cornice or skirting-board, and had, moreover, anything but an even surface. I scraped and cleaned away the whitewash, and then fell to considering how I might best render them more pleasing to the eye.

*The Dado.*—In the first place, as old wainscotting was abundant, I resolved on a dado of dark carved oak; this would be the very thing to harmonise with the woodwork of the fireplace. A few carved panels like those in the chimney corners were still remaining. I had also plenty of plain ones, so nearly of the same size that, with judicious placing, the difference would never be noticed, and these last I proposed to carve to match. Fig. 13 is one of the old panels. The ornament is a common one of the "Restoration" period, and one which requires no great skill or any long time to carve.

My panels were but some 15 in. high, and the whole strip of wainscot only about 21 in., so I had to bring my dado to a proper height by placing next the floor a skirting-board of ebonised wood, and of this I could slightly vary the width so as to bring my odd lots of wainscot to one uniform level. Along the top of the wainscot I nailed another strip of ebonised pine having a moulding on its projecting edge. This finished the dado off neatly. As I have before remarked, old dark oak and ebonised wood go exceedingly well together.

I may mention here that preparing the old oak cost some little trouble—more, indeed, than the actual carving of it. Old oak generally comes into the hands of the collector in a bad state—choked up sometimes with whitewash, beeswax, or dirt, or very frequently with paint. About the middle of last century the fashion appears to have been to paint the oaken wainscot of old rooms *white*. Some of the ancient wainscot that has come to my hands had received not less than half a dozen coats of paint. Whitewash, dirt, etc., yield to hot water, soda, and a scrubbing-brush, but successive strata of paint, which have had a century and a half in which to harden, require more serious treatment. The plan which I have found most successful is to make a strong solution of American potash, to mix it with sawdust, and to lay the poultice thus formed over the paint for a few hours; if cold water and a sponge will not remove the incrustation at a first treatment, they generally will complete the cleansing at a second. After either soda or potash the old oak loses its rich colour and looks pale and poor; but rubbing over with boiled oil, and a subsequent polishing with beeswax and turpentine, will restore it to its original tone.

In nailing the dado to the plugs which I had driven into the walls, I made use of a simple dodge for boring and nailing at exactly the right spot, which may prove a "wrinkle" to those not acquainted with it. Taking a plummet, I tied a knot in the line at a somewhat greater distance from the lead than the plug was from the top of the dado; then, adjusting the plummet so as to bring the bottom of the lead exactly to the middle of the plug, I marked a cross on the wall opposite to the knot. When my wainscot was arranged in place, I had, it will be seen, merely to hold the knot opposite to the cross on the wall and the lead would show with certainty the spot at which to drive the nail.

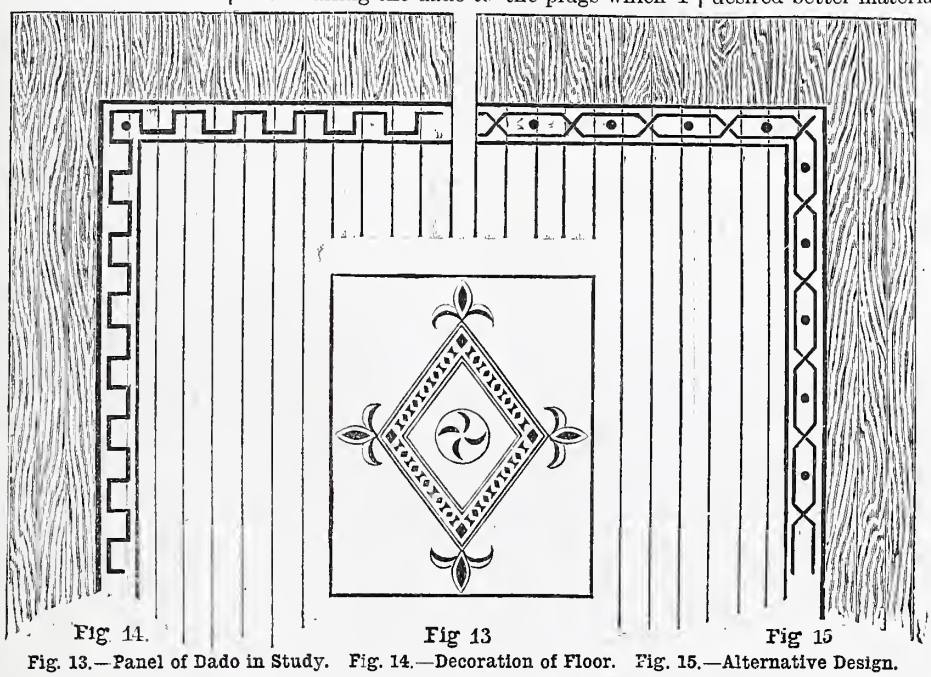

Fig. 14. Fig. 13 Fig 15

Fig. 13.—Panel of Dado in Study. Fig. 14.—Decoration of Floor. Fig. 15.—Alternative Design.

*The Frieze.*—The wall space above the line of my dado I well sized, and papered with newspapers to bring it to a more level surface. I got some steam-struck moulding of two sizes, one 1¼ in. and the other ¾ in. in width (they cost respectively 5s. 6d. and 3s. 6d. per 100 ft. run). These I ebonised, and fixed up the larger against the ceiling by way of cornice, whilst the smaller I nailed below at a distance from it of 1 ft. to form the bottom line of a frieze.

I had proposed to fill this frieze with an embossed paper about one-third gold and two-thirds maroon, but, as we all know, it is easy to imagine a paper just to one's taste, but not so easy to find it in the maker's pattern-book. I could meet with nothing to my purpose, but in the end made by no means a bad shift by using a plain maroon paper, and along its middle running a 5 in. strip of Japanese leather paper, all gold lacquer. As this paper is of extraordinary width (36 in.), three yards, at 2s. per yard, sufficed for the room.

The space between dado and frieze I papered with a plain and rather dark sage green, which went well with the other fittings, and forms an admirable background for pictures, whether in gold frames or black.

*Ornamentation of the Floor.*—The floor has been spoken of as the one good thing in this otherwise uninviting room. It was of fine heart of oak, and the century's wear which it had undergone had served only to season it. Had a floor polished throughout been the thing required, no one could have desired better material on which to operate. But, however pleasant to look upon, a slippery floor is practically objectionable. However enjoyable sliding may be upon the ice, it is not a satisfactory form of exercise for one's own sanctum. As I had no intention of laying down a carpet, I wished to preserve a firm foothold where the floor had to be walked upon. I contented myself, therefore, with oiling and polishing a width of about 2 ft. round the outsides. This strip took a rich colour and made a good ground on which to arrange my carved chests and chairs.

But the break between it and the unpolished part was too abrupt; so, to correct this, I added a line of ornament about 1 ft. in width, as seen in Fig. 14. Having drawn out the pattern on the floor I went over it with a solution of iron, the effect of which was to turn the oak wherever it was touched almost black. Iron turns new oak to a purplish black, but old oak to a very deep rich brown. The solution of iron was made by putting old nails, etc., in vinegar, and it was laid on with a small brush. If applied too freely, there is danger of the stain running along the grain of the wood, and thus in cross lines giving a blurred outline; with, however, a piece of blotting-paper kept beside the worker, superfluous moisture may be readily removed.

When dry, the stained parts should have a couple of coats of varnish; the ornament will then stand wear and tear and the scrubbing-brush for many years. This simple mode of floor decoration gives something of the effect, without the cost, of parquetry. It is one in which a simple pattern may be carried out with no great outlay of trouble, and will be sure to look well. As its inventor I may claim this for it. For an intricate design it is unsuited Fig. 15 is an alternative pattern.

*The Doors.*—To bring the doors in keeping with the old oak and ebonised woodwork, they were painted black; but as one of them led to the open air, it was desirable, for winter comfort, that arrangements should be made for covering them with curtains. Now, the brass and tapestry in vogue for that purpose would scarcely have been in keeping with the home-made fittings of my den, and, what was still more to the point, they were too costly for me. I contented myself with curtains of common green baize, but near the bottom of each I had sewn a double width of old-gold braid 1½ in. wide, and a trifle higher a single width of the same. This made handsome curtains.

For the means of hanging them I had recourse to the dismantled "four-poster" above-mentioned. Its side-rods were of the right length for my purpose, and each of them had at one end a socket, into which the foot-rod screwed. With the fret saw I cut from a bit of hard panel an ornamental javelin head of *fleur de lis* shape, gilded it, and screwed and puttied it into the socket of the rod; the rod itself I enamelled vermilion. Both my doors were in corners, so that one end of the rod in each case fitted into a socket fixed to the wall; the other, the ornamental end, had a hole punched through it and was hung on a hook. Thus arranged, my door-curtains were by no means a costly luxury.

*Some Practical Suggestions.*—In effecting the above improvements in "my den," it must be admitted that in some respects I had advantages which others who may wish to undertake similar work may not have. For instance, one does not find a good oak floor in every room. Yet I would observe that an ordinary deal floor is susceptible of decoration by the same method, only in that case, instead of the solution of iron, one of the usual wood stains must be used.

Nor may everyone have a stock of old oak panelling at his disposal. But, failing this, new match-boarding is always to be got, and is not costly. If the reader will refer to the excellent designs for ornamental arrangements of it in Vol. II., p. 627, No. 91, he will find abundant suggestions for such artistic new woodwork as might well take the place of my old wainscot, and which might be stained to any desired tone.

On the other hand, the rooms in ordinary and more modern houses will have advantages which mine had not; in the matter of windows this will probably be the case. These windows will most likely be larger, and, unlike mine, of greater height than width. Had I such a window space to deal with I should, before filling it with leaded lights, fit in a transom as well as a mullion. Say that its dimensions were 4 ft. 9 in. high by 3 ft. 3 in. wide, and that my mullion and transom each occupied a width of 3 in., I should then divide the space into two upper lights, 18 in. square, and two lower lights, 36 in. by 18 in. The lower lights I should fill entirely with white glass (plain pattern glazing), but in each of the upper ones I should introduce a coloured medallion or cartouche. I should thus get a more effective Elizabethan window than that shown in my last article.

I proceeded, however, just as I have told my readers, in the self-imposed task of turning my house, or parts of it, which at the first glance had appeared so devoid of promise, into one which, to say the least of it, was satisfactory to the eye. I have other portions yet to speak of, but the description of these I am compelled, through want of space, to reserve for future papers.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 96.—"A First Book of Mechanics.

Among the various educational works that have been published of late years by Messrs. Cassell and Company, Limited, there are few that have as good a claim to favourable consideration from schoolmasters and teachers, and acceptance and permanent adoption as a text-book, as "A First Book of Mechanics for Young Beginners," written by the Rev. J. G. Easton, M.A., late Scholar of St. John's College, Cambridge, and formerly Head Master of the Grammar School, Great Yarmouth. The value of the work itself as a text-book is much increased by the numerous examples that are appended to each chapter; but, as the book is intended for the use of schools, it is a question whether it would not have been better to have given the answers to the examples in a separate form, and, for the better assistance of pupil-teachers, to have incorporated with the answers the working of some of the more difficult problems. It is claimed on the title page that the book is "very fully illustrated," and so it is from one point of view, for it contains many explanatory diagrams in elucidation of the text; and it would have been well to have added the words "with explanatory diagrams" to those already quoted, for the popular notion of a fully illustrated work is that it contains plenty of pictures, and no publishing firm or company, perhaps, has done more to create and confirm this popular notion than Messrs. Cassell & Company, Limited. The *raison d'être* of the book itself is best gathered from the preface, in which the author explains that it has been developed from notes compiled by himself, "during a considerable scholastic experience, for the use of pupils preparing chiefly for the London Matriculation, the Preliminary Medical Examination, and the additional subjects of the Previous Examination at Cambridge. In its present form it is intended to supply the want, which has probably been often felt, of a text-book on mechanics treated with mathematical strictness and suitable for beginners whose mathematical knowledge is limited to Euclid's Geometry and to Algebra as far as Quadratic Equations." To anyone who has been brought up according to the old lines of mathematical teaching, it will naturally seem at first sight that the cart has been placed before the horse in taking Dynamics before Statics, but Mr. Easton very ably and, what is more to the point, convincingly shows that this mode of procedure is more reasonable than the old arrangement of Statics first and Dynamics afterwards, and explains that "at the present time there is a tendency to establish the science (of Mechanics) on the foundation of the Three Laws of Motion. In this course of procedure the elementary notions of velocity and acceleration are first dealt with, and next the measurement of mass and force, as involved in Newton's Second Law, is considered. The Parallelogram of Forces is shown to follow at once from the doctrine of the 'physical independence of forces' taught by that Law, taken in conjunction with the geometrical theorem of the composition of simultaneous velocities." In accordance with this, Mr. Easton divides the first part of his book—namely, Dynamics—into two sections: Kinematics, dealing with (1) velocity and acceleration, (2) linear acceleration, and (3) the composition of velocities; and Kinetics, treating on (1) force and mass, (2) Newton's Laws of Motion, with examples, (3) collision or impact, and (4) work and energy. Of these, Kinematics involves the geometry of motion, or motion considered irrespective of its causes, and Kinetics, motion, together with the causes producing it. Then follow Statics, in which the state of rest of bodies is dealt with. That Mr. Easton's book is in every way important and well conceived as a text-book is proved by the *primâ facie* evidence of its arrangement, and the clearness of the matter contained in its pages. There is but one thing that I can venture to suggest by way of improvement, and that is, a short glossary giving the meaning and derivation of scientific and mathematical terms employed in its pages. Such words as dynamics, kinematics, kinetics, velocity, acceleration, statics, etc., present no meaning that the mind can fairly grasp at first sight to those who are unacquainted with their derivation, and thus miss the force of signification that is contained in them; and it is not every teacher who can explain them to his class so as to endow them, as it were, with the life of meaning, and thus to render them better capable of retention in the mind and in the memory.

### 97.—"Condensed Mechanics."

In marked contrast to the volume just noticed, which deals with theory rather than practice, or which, in other words, is theoretical rather than practical, is "Condensed Mechanics," a selection of formulæ, rules, tables, and data for the use of engineering students, science classes, etc., in accordance with the requirements of the Science and Art Department, by Mr. W. G. Crawford Hughes, A.M.I.C.E., First Class Honour Man in Technology, City and Guilds of London Institute, etc. etc., and published by Messrs. Crosby Lockwood & Son. This book is practical rather than theoretical, although it deals, in the first part, as briefly as possible with what the author himself describes as "Condensed Theoretical Mechanics," and in the second with practical work and tables, "it having been the endeavour of the author," as he himself says, to gradually lead up in this manner to problems actually occurring in practice. The tables have been given chiefly as a reference for the student, to aid him in solving the problems presented. The tables deal with data and formulæ on various matters connected with engineering.

### 98.—"Light."

The book which bears a title well calculated to excite the interest and raise a spirit of inquiry in all those who are desirous of learning all they can respecting the wonderful phenomena of Nature, is one of a series of handbooks on scientific subjects published under the general title of "Whittaker's Library of Popular Science," by Messrs. Whittaker & Co. Briefly described, it is an elementary treatise on the subject by Sir Henry Trueman Wood, M.A., Secretary of the Society of Arts. It has been written, as its author tells us, "with the view of providing such information as an intelligent student, unfamiliar with natural science, would require;" and although it has been sought to give the information contained therein in a sufficiently simple form, no attempt has been made to go down to the level of language and style which would be looked for, and, indeed, would be used naturally enough in a book specially intended for young people. A synopsis of the chief contents of the volume may be given as follows: The modern theory of light is first set forth, and it is shown how all phenomena which are matters of common observation may be explained on that theory. The nature of colour is then described, and the mode of its production, and this is followed by an account of the construction and principles of action of the more important optical instruments. Further, an explanation is given of the chemical effects of light and its influence in producing those alterations which are so noticeable in every sun-picture or light-picture produced by photography. Lastly, a brief description is furnished of the phenomena produced by polarised light and fluorescence. In the Appendix, the names of kindred works are given which the student may read with advantage on this subject, after having made himself master of the book now under consideration. THE EDITOR.

## SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

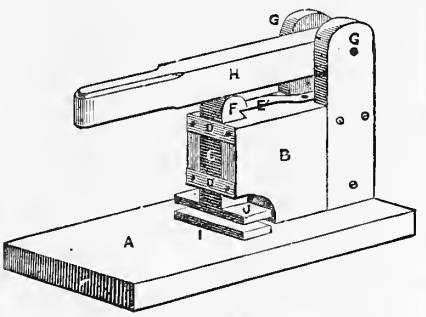
### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Lady's Ring.** — NOVICE. — You say you have bought a lady's gold ring, set with pearls, that has gone white like silver after a few hours' wear; and it also made a green mark on the finger. This ring appears, from the foregoing extract from your letter, to be a swindle—almost without a doubt. Now, to settle the matter one way or another, I should, if I were in your place, take it to another jeweller to test; or, if you have no other near but the one you bought it of, then take it to a chemist. Either will be able to give a decision almost instantly by this simple test: namely, scraping a small part of it quite clean, say one of the sides, so as not to damage it, and then applying aquafortis. If it is 15 ct. gold, there will be very little alteration in colour; but if it is 9 ct., he will find that a dark stain will come over the place that the acid is applied to. If, however, it is base metal, such as German silver, brass, aluminium gold, etc., then it will bubble up and turn pale green, and give off fumes, the acid being in a complete turmoil until its energy is expended. A better way still is by comparing it with known qualities by means of a touchstone, or a piece of Wedgwood pottery will do as well. To carry out this method, a small streak—say about ¼ in. long by ⅛ in. wide—should be rubbed off the ring on to the stone. Then get two or three other known qualities of gold, and make similar streaks with them at the side of the one you wish to test. Finally, apply the aquafortis by means of a pointed piece of glass, right across the whole row. Then, after a few minutes, wipe the acid off; one or the other will be sure to be acted on in the same way as the rubbing from the ring is, that one being, of course, of about the same quality as the one you wish to find out about. If it is base metal, then the whole line will disappear—but so it does with 9 ct. gold; so if you find the rubbing from the ring leaves no mark where the acid has been, then try the other method; but do not flood the work with acid. Now, there is a way that a gold ring can be changed to white in a very little time, and that is by becoming covered with mercury or quicksilver. Be quite sure no such contact has been made before you go further in the matter. The former condition can be restored at a cost of about 1s., I should say. If the ring is a hollow one, and has been water-gilt, it might account for this; for very often the mercury oozes out when any has been left inside, and will completely cover the article. The next thing is with regard to the Government stamp: if that is false, I shall be able to put you in possession of facts that will enable you to bring great pressure to bear on the man that sold you the ring. For that purpose, if it is necessary, you must send me a description of the four or five marks you will find inside the ring. First, the two letters or more that are together; then, is there a leopard's head, or an anchor, or a lion, or what? thirdly, what is the single letter, enclosed in a shield? fourthly, is there a crown, and the figure 15? I want to know this, so that I can find the particular town-mark that has been counterfeited. I do not think I can give you more information or advice, with only your letter before me; and you will clearly understand that nothing but an actual test, carried out by a practical man, can be relied on; so, before demanding your money back, be sure to have one made as I advise. You ought to get a light 15 ct. lady's ring, set with small pearls, for the amount mentioned. I know of no "acid" from a person's body that would cause gold to go white, and I do not believe there is any.—H. S. G.

**Mastic Cement.**—F. A. M. (*Liverpool*) does not mention the purpose, or the kind of material, for which he requires a mastic cement; which makes it difficult to give him a satisfactory answer. We believe that for such substances as will bear heat (glass, china, etc.), the gum mastic, used alone, is sufficient. When jewellers wish to unite two stones, or to mend a broken one, they are said to heat both pieces, apply a little gum mastic to the two faces, and press the two pieces tightly together, keeping them so till cold. This, if well done (with the minimum of gum), makes a strong and scarcely perceptible joint. Gum mastic, merely dissolved in alcohol, is also used as a cement for hard materials. Some cements have been called "mastic," which have no connection with that gum except its name.—M. M.

**Polishing Marble Slab.**—MARBLE.—The slab being already slightly polished, no preliminary work will be necessary. The perfect polish will be given with "putty powder" (calcined tin). This is applied, with water, on a thick felt stretched over a block of wood, which, by means of a handle, has to be kept moving over the face of the slab till the polish is obtained. Putty powder can be got at the colourman's, and if any difficulty is found in getting the proper felt at the same place, it can be had from a marble yard. It is sold by the pound. Perhaps, with the exception of sawing marble, there are few finer exercises for the virtue of patience than polishing.—M. M.

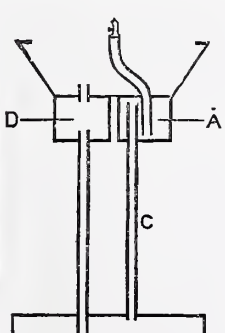
**Die.**—W. H. (*St. Leonard's-on-Sea*).—The die in question can readily be used for *plain* stamping on paper, if mounted in a wooden press made after the style indicated by the accompanying sketch, in which A is a baseboard of 1 in. wood, 12 in. long by 6 in. wide; and B a block of wood 2 in. thick, 6 in. long, and 4½ in. high, into which a plunger, C, 1 in. square and 4½ in. long, is fitted as shown, being retained in its position by two brass strips, D, D, screwed to the front edge of B, and supported by a flat spring, E, screwed to the top edge of B, as shown, and engaging in a notch, F, in the plunger. G, G, are two standards, ⅛ in. thick, 2 in. wide, and 7½ in. high, glued and screwed to B. These standards support one end of a lever, H, which rests upon the plunger, C, to which it transmits pressure, applied to the free end of the lever. The plunger should be



Die for Paper Stamping.

well fitted to B, so as to travel freely with the least possible play; and the spring, E, should be strong enough to lift the plunger and lever, H. The die, I, is fitted to the baseboard centrally, under the plunger, by any convenient means which will admit of its rapid removal and replacement. A counter-plate, J, is formed of a piece of stout sheet brass, rather larger than the die, affixed at right angles to the lower end of the plunger; the counter-die itself being formed of a piece of sheet gutta-percha, softened by heat, cemented to the under-side of the counter-plate, and strongly pressed on the die whilst still soft, the pressure being continued until the gutta-percha becomes cold and hard. If the lettering of the die is sunk, the press so arranged may be used for either plain or colour stamping. If the latter process be decided on, the die must be removed from the press and carefully inked in the letters by means of the ink sold for the purpose (and which, no doubt, the makers of the die can supply), applied with a brush, the surplus ink being removed from the face of the die by rubbing on a flat pad of soft paper. The die is then replaced in the press. The ink left in the sunk letters will be transferred to the paper when placed in position, and the lever depressed with some force. The removal, inking, and replacement of die has to be performed for each sheet of paper stamped. Should plain stamping alone be aimed at, the relative positions of die and counter may be reversed with advantage.—QUI VIVE.

**Self-acting Fountain.** — AMERCKEL. — The sketch of fountain sent (of which you say you have made four, and none of which will play for more than two or three minutes) is an illustration of how a simple contrivance like the "Hero" fountain may be mangled and complicated so as to be useless. The reason your fountains do not play is that you get but a very little water at all into your vessel, A; and, if the jet is anything just discernible, is quickly exhausted. This vessel, A, should be about the same size as the bottom one, and the time the fountain will play through a given jet depends entirely upon the capacity of the vessels, A and B. Your vessel, D, is useless and quite superfluous. There is a fully descriptive article in No. 69 of WORK upon this subject. Try a fountain upon those lines to any dimensions and you will succeed.—C. M. W.



Self-acting Fountain Part.

**Design for Alabaster Panel.**—NEMO.—With every wish to be of service to NEMO, I fear the want of particulars in his letter will forbid my being so to any great extent. He should have said whether his practice in carving makes an elaborate or only a simple design desirable. He should have said whether he wants a figure subject or mere ornament, and if the latter, what style he desires—whether Classical, Gothic, Renaissance, Naturalistic, or what not. If I know *what* he wants, I will gladly (with the Editor's permission) try to draw it for him. If (as he hints) he is in a hurry, I would advise him to try some of the designs already given in WORK. Most people like the Naturalistic style; let him refer to No. 13 (Vol. I., pp. 200-1), and he will there find some good panels of natural fruit and foliage—plum, hip, and blackberry—which he can readily adapt to his dimensions. Though designed with a view to wood carving, they are not less suited to alabaster, or any fine white stone.—M. M.

**Index.**—A. W. (*Stoke-on-Trent*).—You are a little behind date in your kind suggestion. The "good thing" you require in the shape of an index has been published for Vols. I. and II. of WORK, and a third one is in preparation for Vol. III. The price of the Index is one penny.

**Lathe Speed.**—R. T. (*Paisley*).—You wish to turn 8 in. cast-iron wheels on a lathe which gives a speed of one revolution to four treads, and you ask whether this is slow enough. Yes, certainly; it is just about right, and you should be able to turn 10 in. diameters. I cannot tell whether your lathe is strong enough, but think it is sure to be.—F. A. M.

**Spring Roller Blind.**—FIRST TIME OF ASKING.—It is quite impossible for an amateur to make a spring roller for a shop blind; but as FIRST TIME OF ASKING wants to get an idea of the kind of spring used, and of the method of fixing, we reply that the roller is made by special appliances for rolling tin in cylindrical lengths, of the length of the sheet of tin. These lengths, with a lining between each, are soldered together—"sweated," as it is termed. The ends are turned beech blocks; the spindle, an iron rod, from ⅜ to ¾ in. diameter, according to the size of roller. The spring is of wire, specially drawn for the purpose, known as "charcoal spring" wire. This is wound on a revolving mandrel by the roller-maker. The mandrels vary from ½ in. to 1½ in., according to diameter of roller. One end of the cylindrical coil of wire thus made is fixed to one end block, the other to the iron spindle; care being taken to wind the cloth, so that the coil is made tighter when the blind is drawn down. FIRST TIME OF ASKING can get a roller through a blind-maker.—B. A. B.

**Boot and Shoe Repairing.**—G. H. (*Kings Langley*).—Articles have appeared in the following numbers of WORK: 112, 117, 122, 126, 130, and 137.

**Air Pumps.**—AIR PUMP says:—"I do not altogether understand the drawing (see WORK, No. 136, p. 497) of the silk valve, Fig. 2; but I understand its action from your description. I enclose sketch of my idea of the silk valve. Is not the end of your drawing screwed so as to screw into pump barrel?" In reply, I would say that the fear of an unduly long article, together with the thought that this part of the instrument is of easy understanding, kept me from going into details. Fig. 2 represents the valve end of the horizontal tube at the bottom of the barrel in Fig. 1, where the engraver has shown, as clearly as it is possible, the valve, a short tube being soldered to the barrel, into which Fig. 2 is screwed. In the sketch sent AIR PUMP seems to think that the white parts marked C in Fig. 2 are wooden plugs. How he has this idea I do not know. Let me try to make the matter a little plainer. In the tube A a short piece of smaller tubing, B, is soldered, to take the thread; on the end of this is soldered a thick disc, C, which is undercut as shown. On the two opposite sides the undercut is filed off. Across this is placed the silk, as shown by the dark lines. This is carefully tied on, and the undercut prevents its being forced off by the pressure of the air. What AIR PUMP has evidently taken for wooden plugs is the disc projecting on each side beyond the silk. If AIR PUMP could let me know his whereabouts I should be very pleased to send the part in question for his inspection, but I think the foregoing ought to be clear enough. AIR PUMP asks which I would recommend him to make, Fig. 3 or Fig. 6. Well, what does he want it for? If great rarefaction is needed, I should say Fig. 6; but I have given, I think, the advantages of each, and it would be idle to repeat. "Please give thickness of barrel, depth of piston, and mode of packing." I use thin mandrel drawn tubing, such as is used in optical instruments. No thicker is needed. The piston may be 1 in. or 1¼ in., and packed with worsted or cotton. For lubrication do not use grease or oil, but a little vaseline, as I believe there is no acid to corrode the brass as there is in oils. "Please say if the drawing of aspirator is full size." No, Messrs. M. & S.'s in glass is about 8 in. The only fault in the engraving is that the thickness of the metal is shown disproportionately heavy, and that the taper tube, F, should come to a very fine point, the opening simply being a pin-hole.—O. B.

**Tips.**—F. S. (*London, N.W.*).—The inquirer is Mr. Jupp, Wardour Street, London, W.

**Violin Making.**—T. H. C. (*Stroud*).—Articles have appeared in the following numbers of WORK: 105, 110, 114, and 118.

**Graining.**—SOLDER POT.—Articles appeared in the following numbers of WORK: 55, 58, 62, 65, 69, 72, 76, 79, 84, 93, 95, 98, 100, 103.

**Æolian Harp.**—J. H. (*Newchurch*).—An article on this subject appeared in No. 55 of WORK.

**Printing on Bindings.**—CÆSAR.—For printing the title on the backs of books in gold, brass letters are generally used. These have long wooden handles. The letters are sold in boxes or sets containing the alphabet and figures, etc. The process has indeed been given many times in WORK, and very fully in the articles upon bookbinding in Vol. II. You should really look these up, as you will get full instructions of the process, more than I could possibly give here. However, a general idea may be given in a few words. Wash the books with paste water, and after they have become perfectly dry give the title, and other parts where you want the gold to appear, two coats of glaire, allowing the first to dry before applying the second. After both are dry, lay on the gold leaf, using lard or olive oil to make it adhere while working. Lay out the letters to be used and heat them in a gas flame, or otherwise; lift them one by one and press them on the cover upon the top of the gold; the heat of the tool will make the gold to adhere. After the whole title is finished, rub off the superfluous gold with an oily rag. This may help you, but see the articles on the subject already mentioned.—G. C.

**Leather Desk.**—LEARNED.—You want to know how to ornament desks which you have covered with leather and American cloth. There is no book upon the subject that I know of. If you read the articles upon bookbinding in Vol. II. you will get all you require, for the method of treatment in the case of books is the same as you want for your desks. You will require a number of rolls, corners, sprigs, etc., as we call these tools. They are made of brass with wooden handles. When working with them they must be heated. I would advise you not to put gold upon the American cloth, as only those who are well up in this class of work can do it; besides, it is seldom done, as the cloth is used for cheapness. Look up the articles mentioned, and if you require any other instructions write again.—G. C.

**Four-Jaw Chuck.**—R. C. (*Glasgow*).—You may obtain all the information you require in No. 1324 of the *English Mechanic*, with drawing—far more than the Editor would like to put into the "Shop" columns. I will only say, then, that the proportions of the dog as you have them are correct, but that you should certainly have them *forged* and case-hardened after fitting.—F. A. M.

**Picture Framing.**—A WOULD-BE PICTURE-FRAMER.—Articles on Picture Framing appeared in Nos. 5, 8, 70, 106, 109, and 121 of WORK. Your bookseller or the publishers, Messrs. Cassell & Co., London, E.C., will supply them at one penny each, or by post three halfpence.

**Cracked Ball Cups, etc.**—A. T. (*Canonbury*).—The frame must be twisted, or the cups are not put in true. To bell out tube for lap joints: The tube is slit down on opposite angles with a saw as far as you think sufficient. The belling is done by beating and working out on the nose of an anvil if the tubes are large; if tubes are small, a pointed mandrel screwed in the vice is used, or a tinman's stake will do. It is a somewhat difficult job to do satisfactorily, and requires some experience. Bending handle bars: This also requires some experience, as they are usually bent by heating, without filing. To ensure against the tube flattening, ram the part to be bent with dry sand, driving a wad of paper into each end to hold the sand in place; heat the whole of the part to be bent equally, and bend round a curved surface, such as an iron post, or the nose of an anvil, otherwise grip the heated part gently in a vice and bend upwards by putting a rod in each end of the tube to use as levers. When a tube shows oval after being bent, it is brought by heating to a red hue and hammering carefully on the round surface used in bending. Wheel making: Full instructions on wheel making are given in the papers, "The Practical Construction of the Safety Bicycle." Tricycle drawings: The type or style of trieycle would have to be indicated before a drawing could be given.—A. S. P.

**Tandem Tricycle.**—J. B. (*Clapham*).—A tandem tricycle with 24 in. wheels is something out of the common, unless for children. The width should not be less than 33 in. over all. With 30 in. wheels it should not be less than 36 in. wide. To bend a tube, if only a slight bend, heat it to a bright red—that is, the part to be bent. When hot, place a smaller tube in each end and bend gently over a round surface, such as the nose of an anvil. The tube will *oval* slightly at the bend, but that does not impair it in strength.—A. S. P.

**Canvas Cycle Tires.**—RETRENCHMENT.—I am quite unacquainted with the manufacture as well as with the materials of pneumatic tires. Sail-cloth is certainly not one of the materials. It is not at all likely that repairers of cycles will give information regarding the mending of pneumatic tires, for the reason that very few of them possess it, and those who do have paid for their learning, and are not likely to give it away to all and sundry. The repairing of these tires is, I understand, a very ticklish job, and it is useless for your correspondent to try it unless he gets initiated into it by those in the secret, and learns what the proper materials are from them. Altogether, I regard these as a passing fad, that will be a thing of the past in a year or so hence.—A. S. P.

**Wood for Zither.**—B. W. R. (*Liverpool*).—I should think you would be able to obtain what you require in Liverpool at J. Byrom's, 3, Deane Street. He is a violin maker, and most probably would have exactly the kind of stuff to suit you. Failing him, try the organ builders, whose addresses you will find in the directory.—R. F.

**Corner Bookcase.**—J. T. W. (*No Address*).—You do not state whether you require a hanging corner bookcase, or one to stand upon the floor. If the present design suits you, my advice is to construct it in some light, strong wood, the choice of which must be left to your judgment. You will see that my arrangement is somewhat fresh; and by adopting it you will have more space for the disposal of your volumes than would be the case were you to place your books straight across the corner. For instance, one storey in the article shown will afford 30 in. accommodation; whereas, if intended to be *across* the corner, the accommodation would be but a little over 24 in.—unless you made the outside dimensions of the job excessive. A plan is shown in Fig. 2 of the upper carcase. The square space in the corner will be useless, but it is unavoidable; and

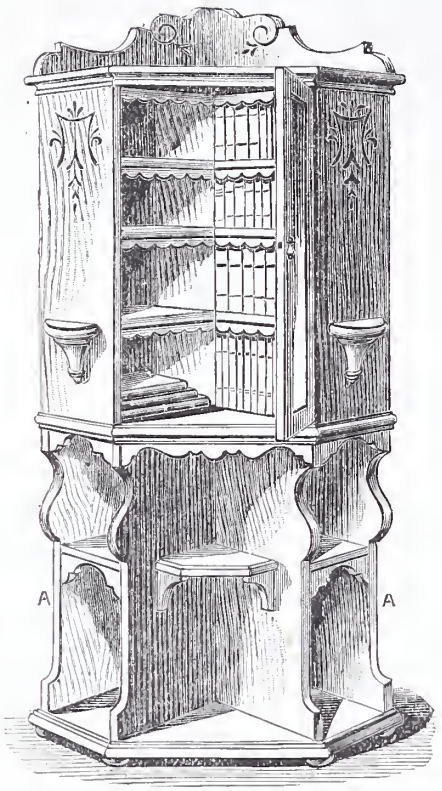


Fig. 1.

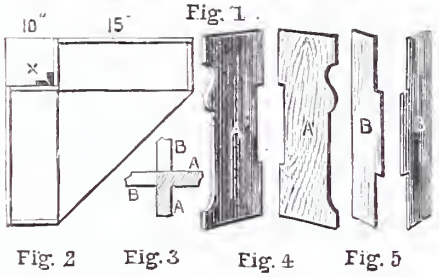

Fig. 2 Fig. 3 Fig. 4 Fig. 5

Fig. 1.—Corner Bookcase. Fig. 2.—Plan of Upper Carcase. Fig. 3.—Plan of United Corners of Boards, A, B, Lower Carcase. Figs. 4 and 5.—How to Shape Boards A and B (in addition to Dovetailing them) to secure the Unison shown in Plan, Fig. 3.

a larger space would be the result of the other arrangement. About the best way to construct the under carcase will be to shape boards, A (Figs. 1 and 3), as shown in Fig. 4, and boards, B, as in Fig. 5, previous to cutting the dovetails. When each pair is then joined together, there will be a corner projection formed by the angle of boards, B, which will fit into a space provided for it by the angle of boards A; and, in like manner, the external angles of A will fit the two spaces in boards B, and appear as in plan (at the corner which unites) in Fig. 3. To secure them thus, it will be necessary to screw stout uprights in the back corner (× in Fig. 2) the whole length behind, to both the portions of A and B which are there exposed to them. Of the upper carcase, two upright boards, 10 in. wide each, will provide the back angular portion; and two 15 in. back boards (to which are united the extreme front boards), joined to them, will complete the carcase, with the exception of all horizontal boards. There should be four corner boards, shaped as in Fig. 2 (the top one only, necessarily extending completely to the corner of the room)—viz., two as bottom and top boards for upper carcase, and two for the same purpose in the lower one. Screw the two carcases together. If other details are not comprehended, refer to back numbers for suitable particulars. You will find a very good design of corner bookcase (hanging) in No. 36, Vol. I.—J. S.

**Bookcases.**—A READER OF WORK.—Designs and particulars of these have been given in WORK, Nos. 15, 36, 44, 48, 52, etc.

**Back Numbers of WORK.**—E. M. (*Blackheath*).—You should address the publishers of WORK, Messrs. Cassell & Co., London, E.C., and not the Editor, for back numbers; and when applying for same, forward stamps for the cost of the numbers and postage.

**Concertina Keys.**—MUSIC.—All English concertinas have the keys about the same distance apart, of whatever make they may be. In the German concertina each key gives two tones; in the English instrument only *one*. English concertinas are not made to be held in the same way as the German instrument. The keys in the instruments made by Jeffreys are the same distance apart as in those by Lachenal.—G.

**Musical Box Comb.**—WHITEFIELD.—The steel comb of a musical box can be repaired, but no estimate of the cost could be given without examining the damage. Messrs. Nicole Frères, 21, Ely Place, London, are makers of Swiss musical boxes, and would doubtless inform Whitefield as to exact cost of repair if he will send his musical box up to them for examination.—G.

**Cornet Valves.**—U. H. (*Sunderland*).—The castings required can be obtained from Messrs. Gautros, 90, Rue d'Angoulême, Paris.—G.

**Watch.**—J. P. (*Liverpool*).—Did the watch keep good time before you had it cleaned, or had it always gone so uncertain? as this makes all the difference; also, have you anything to do with any electric apparatus, or wear an electric belt, or ever go near a dynamo? Your letter is so vague that I am afraid I cannot help in the time-keeping part without further information. Are the hands perfectly tight, or does the minute hand drop occasionally? Did the hour hand always get out, or only since it was cleaned? If so, I should say a tooth has been either bent down or broken off, and this will cause it on the other; if it has always gone wrong, it is possible that the hour wheel has not the right number of teeth in it. I have found this fault more than once; and, on the other hand, I have myself broken or bent a tooth in the hour wheel in trying to move a hour hand which fitted too tight. I am sorry I cannot assist you in the timing of it without further particulars or examining it. I had a difficult case a little while ago, in the timing of a very expensive lever; with me and others it kept excellent time, but two days after delivering it to the owner, he would bring it back ten minutes slow; and quite by chance we found he wore an electric appliance, which, of course, accounted for the mischief.—A. B. C.

**Graining Tooler.**—D. O'S. (*Kerry*).—For any paint brushes, apply to Messrs. Brodie & Middleton, Long Acre, W.C.

**Bookbinding.**—G. W. L. (*Salford*).—The articles on bookbinding appeared in Nos. 6, 9, 57, 61, 65, 69, 72, 75, 80, 85, which can be had of any bookseller, price 1d. each.

**Electric Bell.**—J. H. J. (*Birmingham*).—Instructions how to fit an electric bell appeared in Nos. 12, 18, and 20 of WORK, which can be had of any bookseller, price 1d. each.

**Talking Magpie.**—M. L. C. (*Leicester*).—Your question scarcely comes within the scope of WORK, although you have no doubt been well exercised in endeavouring to make your bird talk. Your proposal to cut its tongue would scarcely tend—would it?—to give the magpie a colloquial turn; but write to the Editor of *Cassell's Saturday Journal*, London, E.C.

**Engine and Boiler Management.**—J. P. (*Darlington*).—These articles appeared in the following numbers of WORK: 119, 123, 127.

**Collie Dog Kennel.**—J. H. M. (*Manchester*).—Consult WORK, No. 90, p. 617, and modify the sizes there indicated to suit your large dog.

**Xylonite.**—E. W. (*Cupar, Fife*).—A full description of this composition appeared in WORK, No. 101, p. 787.

**Puffs of a Locomotive.**—J. D. (*Bradford*).—The answer to your question in my hands is, with its illustrations, too long to appear in "Shop." You must be patient therefore until space can be found for it in the body of WORK, when it will probably appear under some such title as "Compound Engines."—ED.

**Patent Saw Set.**—WOODCUT.—This saw set can be obtained of Messrs. Churchill & Co., Cross Street, Finsbury, E.C., I think, for 7s. 6d.—M. P. B.

**Density of Negatives.**—AMATEUR.—The density of a negative depends on both *exposure* and *development*. A much *over*-exposed negative is nearly always thin unless the development has been suited to the increased exposure. In your case most probably over-exposure is the cause. Try less, and use a well-restrained developer; one with a very small quantity of alkali and large quantity of pyro. The fault may also proceed from light getting to the plate otherwise than through the lens, and so causing a fog effect. Examine your camera and ascertain if it is light-tight. If your plates are good

and your apparatus in good order, the following developer will give plenty of density—with a proper exposure. If you have any difficulty in the matter, the fault lies with yourself. Take for developer: 2 grs. pyrogallic acid, 2½ grs. of ammonium bromide, and 4 grs. of liquor ammonia, with 1 oz. of water. If you get weak images with this and a proper exposure, there is something wrong in your working; but in all probability it is over-exposure.—D.

**White Wood.**—SHOPITE.—For white wood try Cobbett, of Hackney Triangle, E., who can supply it at 2½d. per foot, 1 in. thick; or Latham, 124, Curtain Road, E.C. Be careful to get it dry, as it will be useless for your purpose without.—A. J. H.

**Thermometer.**—AMATEUR.—If you heat the glass tube sufficiently at the point at which you desire to close it, bend it at right angles, and twist off, I do not see how you can fail to close the hole. You say, "I can only succeed in closing it up every time I get it hot enough and then blow down." I confess I do not understand what you mean. If you succeed in closing it up *once* that is all you want. As to where you can "procure ½ lb. of tubes at 6d." I cannot answer, but imagine you should have no difficulty in getting what you require in Liverpool if you look about and inquire.—OPIFEX.

**Wooden Mole Traps.**—R. G. S. & Co. (*Wellington*).—You should advertise your address and goods in the "Sale and Exchange" column of WORK.

**Bent Iron.**—B. H. (*Budleigh Salterton*).—An article on "A Hall Lantern in Bent Iron" appeared in No. 125 of WORK.

**Astronomy.**—ASTRO.—Your question does not come within the scope of WORK. Send the query to one of the educational papers, or to *Cassell's Saturday Journal*.

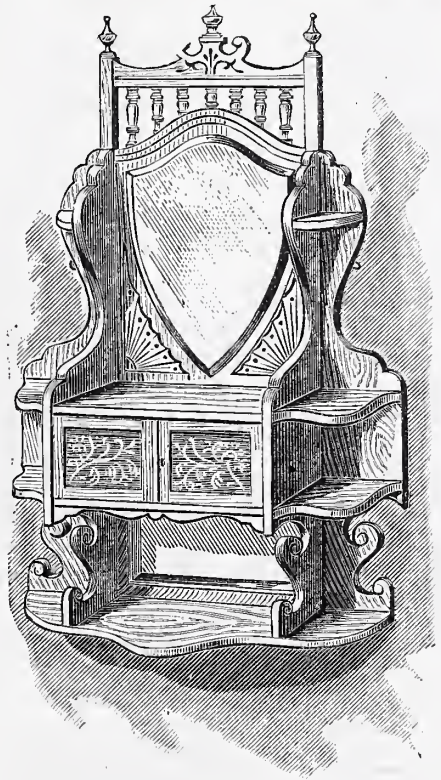
**Spot Lens.**—TOM.—A spot lens is used when it is desired to examine structural details, which might be invisible by direct light. If you take an ordinary condenser and block out the centre rays with a circular patch of paper or varnish, you have a rough-and-ready spot lens. The patch should be fixed on the flat side of the plano-convex lens, and this side should be turned towards the object when the lens is attached to the under-stage of the microscope. By the use of the spot lens with semi-transparent objects, dark grouud illumination is secured. The object is viewed only by the aid of the light rays refracted from the marginal zone of the lens, and these rays are so bent by refraction that they fall on the object without entering the objective. In the best instruments a parabolic illuminator takes the place of this lens.—E. A. F.

**Polishing Fretwork.**—N. R. (*Yeovil*).—Fretwork polished by inexperienced hands is seldom satisfactory; it requires much previous practice on plaiu surfaces. The difficulty is rendered doubly so by trying to do it with new rubbers; the uneven surface of these will give fat edges, and will oftimes catch in and tear out delicate parts of the fret. A plan sometimes adopted, and one which has mueh to recommend it, is to well "body up" the plain surface previous to cutting the fretwork; the surface may then be made to look fairly respectable by carefully applying with a camel-hair brush a coat of spirit varnish. I know of no book on French polishing that I can so strongly recommend as the series of articles on the subject by Mr. Denning, the first of which—"How to French Polish"—appeared in WORK, No. 105, March 21st; and "The Rubber in French Polishing," No. 108, April 11th; followed at intervals by others, which, if followed up by steady practice, will put you on the right track.—LIFEBOAT.

**Estimating.**—GRANT.—I think you would find "The Student's Guide to the Practice of Measuring and Valuing Artificer's Work" would be of great assistance to you. I have a great many questions on this subject, and it really seems to me that the inquirer appears to think that there is some royal road to estimating; but I can assure you there is not, and you will never succeed in finding a book that will give you exactly what you want unless it is a four-panel door or a common sash and frame; and even such simple things as these give a lot of trouble to the beginner, if he has no other knowledge to fall back upon except what he can get from a price-book. There must be some experience beforehand, but a little thinking will help a great deal; for instance, let us suppose you have a shop front to estimate for, of a general thickness of 2½ in.: now, what can you buy 2½ in. stuff for? What will they charge at the mill to cut it out to the sizes required? (You will find they charge this at so much the dozen feet.) Next, what do they quote in Laxton for planing-up stuff at per foot run? How long should a man, in your estimation, take to make such a front when he has the stuff brought to him? Now look in your price-book and see what they give as the price for 2½ in. sashes or shop fronts, and compare their price with your estimate and draw your own conclusions. You must feel your way, as it were—no tradesman or estimating clerk trusts blindly to price-books; there are some things he finds by practice he can do cheaper than at the price given; and, on the other hand, he knows that if he takes the work out at the price quoted for some class of work, he must lose money. I have just made a shop front out of 4½ in. mahogany, 10 ft. high, 12 ft. wide, with a return end 13 ft. high by 6 ft. wide, with horizontal and two upright bars out of 2½ in. by 4½ in., with a 2 in. door and fan over door, all heavily moulded, partly polished, ready for fixing; and this cost £23. Perhaps this may help you, but I doubt if you could find this in any price-book.—E. D.

**Razor Strop.**—G. W. B. (*Cockermouth*).—Make the body of the strop 12 in. long and 2 in. thick in the middle, tapering as shown in the cut (Fig. 2, p. 390, No. 129). You can make the handle any length you like—say, 4 in. This strop will suit admirably for hollow ground razors; better still, perhaps, if of greater convexity than suggested above.—OPIFEX.

**Hanging Mirror.**—D. B. (*Perth*).—I appreciate mechanical talent, and I feel certain that you would grant me the permission to view the result of your skill and labour if I asked; but the fact of your dwelling at so great a distance from me precludes all intention on my part of beseeching this permission. As it is, I believe many a reader would be glad to know how you have devised the brackets and feet of your article to spring out automatically when the flap is opened. Why not send sketches and particulars through the first columns of "Shop?" Now, don't say you cannot draw—that's all nonsense; for, judging by your sketches handed to me, I should say that you could manage it near enough. I give you here what you ask for—a design for a hanging mirror, with drawer or cabinet. I think it is somewhat fresh, and I hope it will meet with your approval. I will not state any dimensions, but



A Hanging Mirror.

merely say that it is advisable for any intending maker, if unable to decide as to size, to rough-sketch an elevation of it on a large sheet of paper, until satisfied as to proportions. If the shaping of the top glass will be too costly, have a square one. I must refer you and other makers, if ignorant upon any point in the joining, to back numbers. I may say, however, that it is preferable to have a post running the entire length at each side. Each shaped piece, too, would be best if made in an entire length. Those at the back, and those projecting, should be the same exactly. Two serpentine-fronted shelves, and a small quadrant shelf at each side, will be effective. I should say, let the bottom board terminate the job, as you will not want to hang the article high enough to show anything underneath it. This board could be in one piece, and serewed from underneath. As a change, I have shown different-sized spindles at the top. Of course, I am aware that spindles are turned, with a view to their being dowelled into *straight* rails, but you will have little difficulty in fitting them as shown. If this doesn't please you—well, alter it.—J. S.

**Cog-Wheels.**—T. J. W. (*Ystalyfera*).—You cannot do better than write to Messrs. Grimshaw and Baxter, Goswell Road, E.C., who are the most likely people to supply your wants. If they cannot, you should write to some model maker, whose address you will get from advertisements in WORK.—P. B. H.

**Saw Maker.**—R. M. B. (*Glasgow*).—You will get good band saws from Messrs. Eadon & Sons, President Works, Sheffield, or from Messrs. Aublet & Co., Curtain Road, London, E.C. I have for some years worked Aublet & Co.'s saws, and, as a rule, they give satisfaction; but I have not had any from Messrs. Eadon since they have had improved machinery for making band saws; although I hear they are now turning out really good band saws. I can highly recommend their circular saws. In reference to the usual pace of band saws, the speed when running over wheels from 36 in. upwards in diameter is from 4,000 to 6,000 ft. per minute. But as your wheels are very small, I would advise you not to run your saws much above 2,500 ft. per minute. The turn being quick, the saws would break quickly if driven at any much greater speed. The gauge of your saws should be about the 22nd gauge—at any rate, not stouter than 21st gauge. If stouter than these gauges, the saw will break after a very little working on such small wheels; and saws at the above gauge cannot be expected to do the amount of work they would do if worked on larger wheels before they break.—A. R.

**Casks.**—J. S. (*Longsight*).—The price for putting a new stave in above would be about 2s. 6d.; for a new hoop, 9d; and a new piece in head, 1s. But surely you have some friend who could make inquiries at a neighbouring cooper's as to what he charges, and compare his prices with those given above, and act accordingly.—E. D.

**Polishing and Staining.**—J. M. (*Manchester*).—The light bay wood can be made to match the darker by wiping over with a weak solution of bichromate of potash dissolved in hot water (½ oz. to 1 pint of water); it may be used cold, and be applied with a piece of rag or sponge, but it is well to try its effects on odd pieces of wood first till you meet with the required strength; or a rather strong solution of common soda-water may be used. It, when dry, the whole is afterwards wiped over with red oil and allowed to stand over-night, it will have a richer appearance. Red oil is made by soaking 2 oz. of alkanet root in 1 pint of clean linseed oil. Use rose-pink as the colouring medium for the "filling in;" it should also be used in the filling for the teak wood, which, by the way, if it requires matching, will be found a more difficult task than the bay wood; it would have to be done by the aid of dyed polishes. If required darker, vandyke brown or black would be needed; or, perchance, a tinge of black and red; if required a red shade, a red polish would be used, but this requires tact that can only be gained by practice. The present Vol. of WORK abounds in information on this subject. Articles have appeared in Nos. 105, 108, 115, 117, 119, 122, 123, 126, and 130, and the answers given in "Shop" touch upon points and difficulties such as you may meet with, and which in writing articles on the subject it is impossible to foresee and explain without rendering the subject unintelligible to the average reader. You will do well to obtain through your newsagent all the back numbers, weekly or monthly.—LIFEBOAT.

**Oil-Coloured Photographs.**—H. W. (*Stockport*).—The photographs are sized with gelatine before applying oil colours. In the pictures alluded to, aniline colours have been probably used, in which case the photograph would show through, which is not the case in oil painting, for in it the colours being opaque hide nearly all the photographic basis. Aniliue colours are merely put on as flat washes of different degrees of strength, but are more adapted to drapery than flesh painting. At one time there was a large sale of aniline colours mixed with albumen of various tints, expressly designed for colouring photographs, and would most likely produce the effects you have seen. Try some of Judson's dyes with a little albumen.—D.

**Grinding Skates.**—H. F. (*Ramsbury*).—I regret to inform you that I have been quite unable to trace any book on the subject of skate grinding, and do not think there is one published.—T. W.

**Throw of Slide-Valve.**—J. W. (*Gateshead*).—If you want to know how to proportion the slide-valve, you should read the papers on that subject in No. 110 of WORK. The whole action must be properly understood to make one aright; the stroke will depend upon the width of the port and the amount of expansion adopted. For instance: suppose your ports are 1 in. wide, if you wish to cut off steam at ¾ of the stroke you will require 1 in. of lap, then the throw of the valve will be twice the port and lap added together—that is, 4 in.—and the eccentricity of the eccentric will be 2 in.—F. A. M.

**Mail Cart.**—W. T. T. (*Houghton-le-Spring*).—An article on this subject appeared in No. 30.

**Overmantels.**—R. B. (*Eltham*).—You will find full particulars of these in WORK, Nos, 2, 3, 5, 22.

**Picture Framing.**—R. B. (*Eltham*).—The following numbers of WORK contain much information upon picture framing: 5, 8, 10, 70, 106, 109.

**Wood-Turning Class.**—WOOD TURNER.—Instruction in wood turning will be included in the subjects of the Finsbury and City of London Guilds and Technical Institute, Finsbury, E.C. Write to the Secretary.

**Electro-Plating Apparatus.**—J. C. (*Heywood*).—You will require a vessel to hold the plating solution. This may be of stoneware, porcelain, or glass, holding from 1 quart to 10 gallons, as required. From this size up to vats holding several hundred gallons, you may get vessels of enamelled iron, wood-lined iron, or lead-lined and match-lined wood. You will also require metal rods placed across the vessels to hold the anodes and the articles to be plated. These may be of copper, brass, brass tube, or brassed iron. From these you must have wires or cables of sufficient size to carry the current from the generator of electricity to the plating solution. The generator of electricity may

be a Wollaston, Smee, Daniell, or Bunsen battery, or a dynamo machine. The battery cells must be large. You will also require such appliances as hair-brushes, scratch-brushes, polishing bobs, and burnishers. Stoneware vessels, containing various acids and alkaline solutions for cleaning the articles, will also be required. The solutions for plating should be those of double cyanide of silver and potassium, and double sulphate of nickel and ammonia. As you are quite ignorant of the art, I should advise you to first read a good text-book on the subject and the articles appearing in WORK.—G. E. B.

**Electrical Shock.**—J. S. H. (*Kirkcaldy*).—"Medical electric shocks" are given by means of an apparatus named a "shocking coil," worked with current from a strong galvanic battery. Illustrated papers on the construction of such coils will be given when space can be spared for their publication. As there is scarcely a back number of WORK in which there is not something about "electrical apparatus," I should advise you to get the whole.—G. E. B.

**Blue Prints.**—A. B. (*Bow*) uses the solutions too concentrated. Use instead 70 grs. of the potash salt and 100 grs. of the iron salt, and only mix the two solutions just before use; they will not keep mixed. Apply evenly, and dry in the dark.—D.

**Half-Plate Camera.**—G. L. (*Halifax*).—If G. L. will refer to the first volume of WORK, he will find instructions for making a whole-plate camera. He must bear in mind that a half-plate, so called, is rather larger than the half of a whole-plate, measuring 6½ in. by 4¾ in. In making the camera, the substance of the wood may be nearly as great as for the whole plate. The length of the bellows need not exceed 12 in. The only important differences are in the size of the dark slides and frame of camera and focussing screen, which must be made to suit 6½ in. by 4¾ in. plates. The baseboard, being so much less, need not be made so strongly as that recommended for the larger size. Of course, this applies to the whole apparatus. In examining the diagrams given, it will be seen that so long as the *principle* of the apparatus is not violated, many little alterations may be made in the construction to save labour, but not interfere with its working.—D.

**Refracting Telescope (Huyghen's Achromatic Eye-piece—Magnifying Powers).**—J. T. S. (*New Brompton*).—Your letter has interested me very much because of its genuineness. Persevere with your experiment. If, as you say, your object lens is 48 in. in focus, and you use for eye-picce your ½ in. plano-convex lens, then the magnifying power must be: $\frac{48}{\frac{1}{2}} = 96$; it cannot be anything else. If you use the ¼ in. for eye-piece, then the power is $\frac{48}{\frac{1}{4}} = 192$. But in either case you will not get a satisfactory result; for your object glass, being common, is non-achromatic—*i.e.*, uncorrected; and the using a single lens for eye-piece increases the error. I presume that you do not see your way clear to buy an achromatic object glass in place of your common one. An ordinary achromatic object lens, 2½ in. in diameter and 36 in. in focus, costs, at a good London house, 18s.; and, therefore, the best thing that you can do is to make for yourself a proper eye-piece. To do this, proceed as follows:—Procure two plano-convex lenses, having their respective focal lengths in the proportion of 1 to 3, thus: ¼ in. and ¾ in., or ½ in. and 1½ in. Place these at a distance apart equal to one-half their joint focal lengths, $\frac{\frac{1}{4}+\frac{3}{4}}{2} = \frac{1}{2}$ in. in the first case; $\frac{\frac{1}{2}+1\frac{1}{2}}{2} = 1$ in. in the second case. The plane sides should be towards the eye, to which, of course, the smaller lens should be the nearer. Between the two lenses, and in the focus of the first, should be placed a stop. The central hole, which defines the field of view, will need to be slightly smaller in diameter than the smaller of the two lenses used. The magnifying power of this combination will be about twice as great as the power which the larger of the lenses, used alone, would have. Thus, you may calculate easily what lenses will give you a fixed power. For example: with lenses ¼ in. and ¾ in., placed ½ in. apart, the power would be, with your 48 in. focus object glass: $\frac{48}{\frac{3}{4}} \times 2 = \frac{48 \times 4}{3} \times 2 = 64 \times 2 = 128$. This is quite high enough for you to attempt to use. The better plan, indeed, would be for you to get a plano-convex 1½ in., and with this and the ½ in. that you have, to make an eye-picce of power—

$$\frac{48}{1\frac{1}{2}} \times 2 = \frac{48 \times 2}{3} \times 2 = 32 \times 2 = 64.$$

This power would show you the belts and moons of Jupiter, and even the rings of Saturn. Your idea that the power you have so far obtained is only 10 is perhaps due to over-strained expectation. A telescope is always disappointing to a beginner. Get used to it, and learn all its faults, and then you will be able to see a great deal more. As for Venus, it is the most trying object of them all. Many a good telescope shows faults when it is turned on to Venus: she is so bright and so dazzling. When you would observe her, first stop your object glass down to about 1 in., and then you will see her phases. Do not aim at high magnifying power. As a young student, lay this to heart: that more pleasure and profit can be obtained with a telescope *firmly mounted* (how important is this!), and armed with a low power, than with a loosely mounted instrument armed with a higher power. Experienced astronomers, as a rule, use low powers, except for very special work. I should not advise you to attempt to make an achromatic object glass for yourself; and if you were to attempt it, a lathe would have very little to do with it. Lenses are not made on lathes. But you might make a reflecting telescope; and when this 48 in. of yours is in working order, and satisfies you, if you write to the Editor again, he will send your letter to me, and I will tell you more about it.—E. A. F.

**Wood-Carving Book.**—F. G. P. (*Walsall*).—"Hints on Wood Carving," by E. Rowe, is the cheapest, best, and certainly the most practical manual on the subject I know. It can be obtained, post free, for 1s. 1d., from the School of Wood Carving, City and Guilds of London Technical Institute, Exhibition Road, South Kensington. It contains much useful information respecting tools, designs, etc. Fred Miller's book is published by Wyman, Little Queen Street. Its price is 5s., or 4s. 6d. It treats of wood carving from the historical standpoint rather than the practical. The number of tools required depends entirely on the character of the carving you intend to do; but very little can be done with less than eighteen, or twelve at the least. They cost from 10d. to 1s., depending on whether they are sharpened or not. They can be bought at the above-mentioned school ready for use, or from Buck, 242, Tottenham Court Road. Their sizes vary according to the work they have to do.—M. E. R.

**Books on Electric Bells.**—J. W. (*Homerton*).—"Electric Bells, and All About Them," by T. R. Bottone, and "Practical Electric Bell Fitting," by F. C. Allsop, are the only books on this subject. If you are in a fix, let me know the particulars, and I will try to help you out of it in the columns of WORK.—G. E. B.

**Tool for Cutting Screws in Wood.**—W. H. N. (*Oldham*).—You can purchase screw boxes and taps for cutting screws in wood, manufactured by Messrs. Peugeot Brothers, through any dealer in tools, of their agent, Mr. Alexander von Glehn, Idol Lane, London, E.C. The sizes range from ¼ in. to 3¼ in. You had better write to Mr. Von Glehn for a price-list.—ED.

**Ground Glass Imitation.**—R. M. (*Glasgow*).—I am sorry that you have failed to obtain satisfactory results when following my directions in No. 9, Vol. I. Perhaps you would succeed if you enclosed the lump of white-lead putty in a piece of rather coarse muslin. Your glass may have been damp or dirty, or your putty too wet or too dry. As you say, common salts (Epsom), dissolved in water, and applied to glass, produces a frosted appearance; or a saturated solution of alum produces the same effect; but, for this method the glass must be placed in an horizontal position until crystallisation takes place, when the frosting must be protected by the application of a coating of gum-water. This is, of course, a very temporary kind of work. You might try sugar of lead, rubbed up in boiled oil, and applied with the end of the bristles of an ordinary hog-hair brush, dabbing the surface of the pane lightly, until the whole is evenly muffed. When perfectly dry, a pattern may be made by drawing in the design with a fine brush dipped in a strong solution of caustic potash, and then wiping off with a soft cloth. This will last for a long time, and needs no protection.—OPIFEX.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Fretwork.**—W. M. (*Brixton Hill*) writes:—"I have so far been using a hand fret saw, but wishing to work more expeditiously, thought of investing in a treadle machine. Can you or any reader tell me if there is any such machine capable of practical work, as I have been told all such machines are useless, being only made for selling to inexperienced amateurs."

**Mangle Rollers.**—LEARNER writes:—"I shall be glad if any reader would give me a description of the method of turning mangle rollers, and the different sizes of tools required (rest included); and if it is possible for me to turn them in a 5 in. centred lathe."—[LEARNER might have said whether he required wood rollers.—ED.]

**Tailoring.**—APPRENTICE will feel obliged to any reader who will tell him where he could get good books on cutting.

**Alarum Clock.**—A. S. (*Lavender Hill*) writes:—"Can any of my fellow readers tell me where I can obtain a continuous alarum clock?"

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. B. (*Kent*); S. L. (*London, N.W.*); C. F. C. (*Lincoln*); M. M. F. (*Spenshaw*); ENGINEER; M. M. (*Rosecea*); J. T. H. (*South Shields*); E. M. (*Rainham*); CIRCULAR WINDMILL; WORKITE; NELSON; A. R. (*Scorrier*); W. E. D. JUNR. (*King's Lynn*); D. (*Kilmarnock*); E. J. (*Plumstead*); J. M. (*Glasgow*); A. V. S. (*Westbourne Park*); DUMMY; R. G. (*Settle*); J. W. W. (*Chesterfield*); J. W. H. (*Edinburgh*); F. C. (*Cardiff*); G. T. (*Liverpool*); F. C. S. (*Manchester*); A. R. T. (*Birmingham*); H. R. (*Chasewater*); A COUNTRY CABINET MAKER; NOVICE; F. J. (*Exeter*); T. M. (*Liverpool*); W. A.; N. M. (*Norwich*); J. T. (*Kensington Barracks*); J. W. (*Forebank*); C. F. W. M. (*Enfield Lock*); ERIC; G. R. D. (*Chatham*); W. C. A. (*Ware*); G. T. (*Hollinwood*); CUTTER; V. (*St. Helen's*); M. B. (*Brighton*); C. R. (*Birmingham*); J. H. (*Bury*); PATIENCE; T. P. (*Duckinfield*); J. G. (*Glasgow*); CANTAB; JOINER; E. J. A. H. (*Portslade-by-Sea*); A. R. R. (*Redcar*); ELECTRIC LAMP; J. P. (*Handsworth*); R. W. C. (*Oxford*); A. B. C. (*Arbroath*).

FOURTH EDITION. Price *7s. 6d.*

**Practical Electricity.** A Laboratory and Lecture Course, for First Year Students of Electrical Engineering. By Prof. W. E. AYRTON, F.R.S., Assoc. Mem. Inst. C.E. With Numerous Illustrations.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

## *SALE AND EXCHANGE.*

**Victor** Cycle Co., Grimsby, sell Mail-cart Wheels and Parts. [15 R

**Who's Lunt?**—Why, the Best Man for Joiners' Tools, of warranted quality. Send stamp for our Seventh Edition Reduced Price List.—LUNT, Tool Merchant, 297, Hackney Road, London, E. [13 R

**The Universal Amateur Exchange.**—Electrical, Optical, Mechanical, Chemical, Photographic, etc. Established 1862. Catalogues, 2d.—A. CAPLATZI, Chenies Street, Bedford Square. [8 R

**Joiners' Tool List,** post free.—BOOTH BROTHERS, Dublin. [21 R

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath. 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repousse Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). [4 S

**Six Large Comic Fretwork Designs,** 1s. 1d.; sample, 3½d. Forty Small Designs, 7d.; Sample Sheet of Six, 2½d. Eiffel Tower, 1s. 1d.; all free.—TAYLOR'S Fretworkeries, Blackpool. [25 R

**¼ h.-p. Horizontal Steam Engine,** as described in the pages of WORK by F. A. M. All the castings, forgings, and other materials required in the construction of these excellently designed Engines, may be had from H. MILNES, Ingleby Works, Bradford. Prices on application.

**The Buyers' Guide** to the best Books on Mechanical Subjects, with table of contents, price 6d. In cloth, 1s. 6d.—Published by BRITANNIA CO., Engineers, Colchester.

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of three thousand new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Machinery wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send two stamps for Register to Box 505, BRITANNIA TOOL FACTORY, Colchester. [26 R

**Inexpensive and Artistic Materials** for all classes of decorations. Send for detailed lists.—W. T. CRAIG, Wick. [27 R

**Turning Designs** accurately drawn. First and second series, 1s. 7d. each, free.—WALKER, 41, St. Helen's, Ipswich. [1 S

**Fairy Bell Pegs.**—6d. dozen, postage 2d., or three dozen post free. Wire, 4d. per ring.—MARSH, Temple Street, Bristol. [2 S

**Violin.**—Splendid copy Amati, rich brilliant tone, fine preservation, complete, with baize-lined case and silver-mounted bow. Only 15s. 6d. lot; great bargain. 20s. worth of good unsoiled music given in gratis. Most genuine bargain obtainable.—Write, GRAHAM, College Building, Ipswich. [3 S

**Try Bolton,** Burmantofts, Leeds, for Fretwork Materials. Lists free. [28 R

**Christmas Presents.**—Splendid fretwork outfits, complete, 1s., 1s. 6d., 2s. 6d., 2s. 9d., 4s., 4s. 6d; and magnificent outfits in polished beechwood boxes, 9s. 6d. 6 foot fretwood, 2s. 6d.; 12 foot, 4s. Saws, 1s. 6d. gross. All free. Good designs from 1d. each. Sample designs, 1d.—TAYLOR'S Fretworkeries, Blackpool. [29 R

**Goodell Lathe,** Fretsaw, attachment, drill and tools, for sale. CHILDS, 42, College Street, Islington. [5 S

**½ h.-p. Horizontal Engine,** wants finishing. Workmanship guaranteed. Price 30s.—Particulars of G. HINGE, High Street, Hanwell, W. [7 S

**"Electrical Engineering"** (Slinger and Brooker), "Domestic Electricity" (Hospitalier), "Electro-Plating" (Urquhart); all clean, 12s.—J. ROBISHER, Ogden Street, Ardwick, Manchester. [6 S

# BEECHAM'S PILLS.

**WORTH A GUINEA A BOX.**

*A Wonderful Medicine for all Bilious & Nervous Disorders,*

SUCH AS

## Sick Headache, Constipation, Weak Stomach, Impaired Digestion, Disordered Liver, &c.

BEECHAM'S PILLS have been before the public for half-a-century, and are to be found in every English-speaking country; they have by far the largest sale of any patent medicine in the world.

Prepared only, and sold Wholesale, by the Proprietor, THOMAS BEECHAM, St. Helens, Lancashire. Sold by all Druggists and Patent Medicine Dealers everywhere, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each. *Full directions with each box.*

## DELICIOUS TEMPERANCE DRINKS.

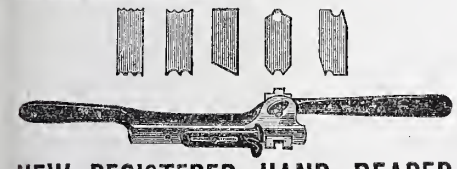
MASON'S NON-INTOXICATING BEER. MASON'S WINE ESSENCES.

These Essences produce in a few minutes a delicious Temperance Wine or Cordial, Ginger, Orange, Raspberry, Black Currant, Lime Fruit, etc. One Tablespoonful of Mason's Extract of Herbs makes one gallon of Splendid Beer, refreshing and non-intoxicating.

A Sample Bottle of either Essence or Extract sent on receipt of 9 stamps, or a bottle of each for 15 stamps.

AGENTS WANTED.

NEWBALL & MASON, *Nottingham.*



## NEW REGISTERED HAND BEADER,

With Six Irons, cutting Twelve different patterns in Reeds, Quirks, Rebates, Beader, Hollow Fancy Reeds. Length, 9½ in. Post free, 2s. 6d. Send for our 200-Page Catalogue, 700 Illustrations. By post, 6d.

MOSELEY & SON, 323, High Holborn.

COMFORT WARMTH & HEALTH IN WINTER

FOR 3/11

We will supply you a very good Unshrinkable Flannel Shirt in pretty Greys and Fawns that will wear twice the length of time of any other shirt. Send size of neckband to West Riding Flannel Co., Leeds. Carriage Paid on two or more shirts. Write for patterns.

ESTABLISHED 1851.

## BIRKBECK BANK,

Southampton Buildings, Chancery Lane, London.

THREE per CENT. INTEREST allowed on DEPOSITS, repayable on demand.

TWO per CENT. INTEREST on CURRENT ACCOUNTS calculated on the minimum monthly balances, when not drawn below £100.

STOCKS, SHARES, and ANNUITIES Purchased and Sold.

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH or A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY, as above.

The BIRKBECK ALMANACK, with full particulars, post free on application. FRANCIS RAVENSCROFT, Manager.

GIVEN AWAY! YOUR NICKEL SILVER

*PEN & PENCIL CASE,*

with your name in Rubber, complete, 7½d. Stamps, or for your Name or Monogram. Rubber Stamp for Marking Linen or Paper, enclose 3½d. stamps or postage, &c. Mention this paper, and address—

**Crystal Palace (John Bond's) Gold Medal Marking Ink Works, 75, Southgate Road, London, N.** CAUTION: Original Patentee of the 6d. and 1s. Crystal Palace (John Bond's) Propelling Metallic Marking Ink Pencil.

## THE DOUBLE-POINTED NAIL

(*Durrans' Patent*).

**For Dowelling Joinery of all Kinds.**

INVALUABLE FOR CARPENTRY OF EVERY DESCRIPTION.

*Particularly Useful to Amateurs.*

Machine Steel cut Nails, ¾ in., 1 in., 1¼ in., 9d. per gross; 1⅜ in., 1s. per gross.

Sample boxes, assorted sizes, 6d.; by post, 8d.

These Nails are a perfect protection for fence tops and trellis work, preventing the ravages of trespassers and cats.

**Malleable Iron Fence Nails.**

Sizes, 1¾ in., 2 in., 3 in., 4 in., 5 in., and 6 in., in 7 lb. bags, 3s. 6d.; per cwt., 55s.

*Durrans' Patent Nail Syndicate, Limited,* 43 and 44, Upper Baker Street, London, N.W.

## PAINTERS!! GRAINERS!! DECORATORS!!

**The Art of Graining** is now complete, and contains 20 splendid plates. The finest example of graining ever published. Each plate is 18 x 13.

*Price in Parts, 36s. Bound, 42s.*

30 pages of Technical Instruction.

**Painted Wall Decoration.**

2/6 The Christmas Number of the Journal of Decorative Art. 2/6

A Perfect Manual of Design and Technical Instruction on

SURFACE DECORATION,

containing

10 LARGE SHEETS OF WORKING DESIGNS, BORDERS, DIAPERS, POWDERINGS, ETC. ETC.

(*Price 2s. 6d.; post free, 2s. 9d.*)

*For full particulars, see the November Number of* **The Journal of Decorative Art.** (7d.)

W. G. SUTHERLAND,

15, ST. ANN STREET, MANCHESTER.

SIMPKIN, MARSHALL & CO., LTD.,

317, STRAND, LONDON.

*NEW YEAR'S GIFTS.*

## Cassell's Classified Catalogue,

containing particulars of upwards of One Thousand Volumes suitable for PRESENTS, ranging in price from

**Threepence to Fifty Guineas,**

will be sent on request, post free, to any address.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

A COMPLETE NOVEL, entitled "The Fate of Sister Jessica," by F. W. ROBINSON, Author of "Little Kate Kirby," appears in

## CASSELL'S ILLUSTRATED ALMANAC AND COMPANION FOR 1892.

Now ready, price 6d. (post free, 8d.), which also gives full particulars, with Portraits, of Champions of the Year in various Sports and Pastimes, Notable Men of the Year, etc.

"'Cassell's Illustrated Almanac and Companion' is now entitled to a foremost place in public estimation alike for its useful features and its light literature. Mr. F. W. Robinson contributes an excellent story, 'The Fate of Sister Jessica,' effectively illustrated by Mr. Paul Hardy. The article entitled 'British Sports and their Champions,' is the most succinct account of the year's doings in every branch of sport, and is illustrated." —*Daily Chronicle.*

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

*Now ready, price 6d.*

# "CHRISTMAS ARROWS,"

BEING THE EXTRA CHRISTMAS NUMBER OF

# THE QUIVER, 1891.

CONTENTS.

*A Complete One Volume Story, entitled*

**Wyhola; the Rose of Corve Dale.** By EVELYN EVERETT GREEN, Author of "The Stronger Will," "Dorothy's Vocation," etc. etc. With 13 Original Illustrations.

**True as Steel.** By IDA J. LEMON, Author of "That Little Woman," etc. Illustrated.

**What she asked from Santa Claus.** By the Rev. P. B. POWER, M.A.

**Light, Life, and Love.** A Meditation for Christmas. By the Very Rev. the DEAN OF RIPON.

**The Holiest Place.** By J. C. TILDESLEY.

**Bess.** By M. E. WOTTON, Author of "Beauty and the Beast," etc. etc. Illustrated.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

# FRETWORK FOR AMATEURS

OF BOTH SEXES AND ALL AGES

The most Fascinating and Profitable of all Home Pastimes

250,000 Fretwork Designs, 100,000 ft. Solid & 3-Ply Fretwood Veneers, etc., 1,000 gross Fretsaws, etc., always in Stock,

**To Beginners—A Complete Outfit, 2s. 6d., post free.**

Comprising 12 in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient planed Fretwood, and full Instructions. 6 ft. assorted planed Fretwood, 2s. 6d.; 12 ft. ditto, 4s. 3d., post free. Book containing 12 sheets full-size Designs, 1s. Fretsaws, 1s. 4d. per gross.

New Catalogues of Machines, Designs, Wood, Tools, etc., with 60 pages and 600 Illustrations, and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design SENT GRATIS with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear. N.B.—All orders MUST be accompanied by remittance. Apply—**J. H. SKINNER & CO.**, Manufacturers of Fretwork Materials, **W** Department, **East Dereham, Norfolk.**

## SILICO ENAMEL

**SAVES CLEANING & POLISHING**

**SILVER, PLATE, BRASS, STEEL, &c.**

"SILICO" is a thin liquid enamel, finer than varnish, easily applied to all polished metals, dries in a few minutes, and forms a smooth invisible film that not only protects the metals from rust or tarnish, but preserves the brilliant appearance. It will not injure the richest metal, and can easily be removed if desired. As supplied to Government, Museums, etc.

### DECORATION OF FIREPLACE IN REPOUSSÉ WORK, TILES, OR PAINTING.

BY J. EADIE-REID.

THE designs for panels to be used in the decoration of a fireplace which are here submitted to the notice of our readers, although they are intended primarily for execution in copper, are equally adapted to reproduction in tiles or painted decoration.

The drawings themselves are intended rather as suggestions to the workman than as actual copies. In carrying out such a design, I would advise the designer to work it carefully on a small scale—say, inch scale—determining the place of every detail before commencing his full-size cartoon. By acting on this hint he will save much time and patience. For painted decoration I would use some simple harmony of contrasting colour, outlining the principal forms with a rich dark brown. The ornament will require a similar treatment. Whatever method may be adopted in carrying them out, see that there is breadth in your masses and clearness in the drawing of your forms.

The figures, as will be noticed, represent Summer and Winter, and may be taken as being fairly characteristic of these seasons of the year. They will be found useful for the ornamentation of articles of furniture and other things, as well as the decoration of a fireplace. Thus, for instance, they may be utilised for painting the panels of the doors of a sideboard, or for windows in painted glass, or pieces of glass that are often seen hanging in windows. A clever decorator will be at no loss as to any use to which they may be put.

Design for Decoration of Fireplace in Repoussé Work, Tiles, or Painting.

## THE WINTER ELECTRICAL MACHINE AND ACCESSORY APPARATUS.

BY CHAS. A. PARKER.

SLOW DISCHARGE OF LEYDEN JAR—ELECTRICAL CHIMES—IMAGE PLATE—STAND FOR DANCING FIGURES—INSULATING STOOL—ELECTRIFIED HEAD OF HAIR—BUTTERFLY NET—ELECTRICAL WHIRL—ELECTRICAL INCLINED PLANE—LUMINOUS EGG STAND—APPARATUS FOR FIRING ETHER—FIRE HOUSE—THUNDER HOUSE—VARNISH.

IN the previous article description was given of an arrangement whereby a Leyden jar might be slowly and imperceptibly discharged automatically. By the following slight modification of the apparatus previously described, this slow discharge of a Leyden jar may be made the means of ringing a couple of bells until the charge is finally exhausted, as will be understood by reference to Fig. 34, which is an illustration of the apparatus about to be described.

*Slow Discharge of a Leyden Jar by means of Bells.*—First prepare the wooden base, which may take the form of a mahogany board, 9 in. by 12 in., supported on four feet. These feet may be turned in a lathe similar to the supporting feet of the machine previously illustrated in Fig. 18 (p. 465); but they must, of course, be smaller, or, if preferred, they can be sawn from a suitably moulded piece of mahogany, cut in the form of Fig. 35. When the stand has been prepared, it should be polished or varnished, according to taste, after which a disc of foil, a trifle larger than the jar to be employed, is pasted on to the upper surface of the stand near to one end, with a 4 in. narrow strip of foil projecting from one side of the disc across the base to nearly the opposite end, as will be seen by reference to Fig. 36, which represents a plan of the top of the stand. A turned wooden socket, about 1 in. in diameter and 1½ in. or 2 in. high, is now prepared and affixed to the stand immediately over the outer end of the strip of foil. When this has been done, a 10 in. length of stout brass wire should be pointed at one end slightly, and then bent to the form of a hook, with a smaller hook turned up at the extreme point, something afer the fashion of a shepherd's crook. Now procure a couple of small bells, such as are used on alarum clocks, and slide one of these on to the wire support just prepared, holding it near to the curved end whilst a small brass ring is being soldered to the middle of the wire, in order to retain the bell in position. Thus prepared, the wire is tightly fitted and cemented into a hole bored through the small socket, after which a small ball of metal is suspended from the hook of the support by means of a silk thread. The stand being completed, the second bell is now supported on the stem of the Leyden jar at a corresponding height to the other, by means of another wire ring soldered round the stem in a similar manner to the previous one. If the jar is now charged and then placed on the table over the circular disc of foil, it will attract the small clapper, and cause the latter to swing backwards and forwards, ringing the bells until the charge is exhausted.

*The Electrical Chimes* (shown in Fig. 37) will be found a much more convenient method than the foregoing for illustrating the phenomena of attraction and repulsion as applied to bells. A 6 in. length of brass rod is first bent into the form of a hook at either end, in order to form the cross-bar from which to suspend the bells, and another piece of slightly thinner wire is then twisted in a loop in the middle, and bent in the form of a hook at either end, of sufficient size to grip the central bar just prepared, after which the two are joined together by means of a touch of soft solder. Now cut off a couple of 7 in. lengths of moderately stout brass wire (or brass chain), and having first turned up one end of each in the form of a small ring, slip one of the bells previously mentioned on to the wire, so that it may rest on this ring, and then turn up a similar loop at the other end of the wire, but do not close this until the bells have been slipped on to the end of the cross-bar. The bells are shown suspended by chains in Fig. 37, and A represents the alternative plan above described. For the clappers, a small block of brass about ⅜ in. long is filed up to a neat form, and then threaded on a piece of silk, which is put through a hole drilled in the metal. Thus prepared, a third bell is suspended from the centre of the cross-beam by means of a piece of silk thread tied to the latter, and from the underneath of this bell, a suitable length of brass chain should be hung, in order to make provision for the escape of the electricity into the earth. Lastly, the two clappers are hung from the cross-beam, one on either side of the central bell, and midway between the others, care being taken to see that the bells and clappers are all on the same level. The bells are now hung from the prime conductor, with the piece of chain from the centre bell in communication with the earth. On the machine being put in motion the outer bells will become charged with electricity, which will attract the two clappers, and cause them to fly backwards and forwards from the centre to the outer bells during the time that the machine is worked. Any dealer in watch and clock makers' materials will be able to supply small alarum clock bells, similar to those shown in the illustration, for a few pence.

*The Image Plate*, for dancing figures, represented in Fig. 38, is a very amusing piece of apparatus for exhibiting the effects of attraction and repulsion by means of a couple of small pith figures. The usual description of image plate takes the form of a pair of thin discs of tin or brass plate. The top one is suspended from the prime conductor by means of a short length of chain attached to a hook or collar soldered to the plate, and the lower disc, which is called the table, is supported on an ornamental turned wooden pillar, provided with a circular base. The figures employed for the purpose are carefully cut from elder pith by means of a keen knife or razor, being afterwards painted in as life-like a manner as possible.

*A Stand for Dancing Figures*, which is far preferable to the above, is illustrated in Fig. 39. A piece of mahogany about 12 in. square is carefully planed and moulded to form the base, which should be slightly raised from the table by means of four mahogany supporting feet. A couple of ¾ in. holes are now bored through the base on opposite sides, in order to receive the stems of a couple of sockets for the supporting rods. These supporting rods take the form of two short lengths of glass rod, ⅝ in. in diameter, cemented into a pair of suitably turned wooden sockets, which are furnished with short projecting pins, in order that they may be fitted into the holes prepared for their reception in the base. A couple of hollow brass stool balls, which will just fit over the tops of the glass rods, are now soldered to the ends of a 12 in. length of stout brass wire, which is afterwards bent in the form of a loop round a perfectly sound cork, in the manner shown in Fig. 39. When this has been done, a 9 in. disc of tinfoil is very carefully cut and pasted on the centre of the base in the position indicated in the illustration, after which the sockets carrying the supporting pillars should be glued into the holes in the base, and the knobs of the wire arch afterwards cemented on to the tops of the glass pillars. A 3 in. or 4 in. brass disc is now soldered to the end of a 6 in. length of brass rod, which is then pushed through the cork fitted into the central loop of the arched wire, after which a small brass knob is soldered on to the upper end of the brass stem, and when quite finished this apparatus may be varnished or polished, according to taste. By means of this arrangement the upper plate can be readily adjusted to suit any kind of pith figures or pith balls, and if desired may be worked at some distance from the machine by means of a chain led from the prime conductor and hooked on to the upper knob of the stand.

*The Insulating Stool*, illustrated in Fig. 40, will be found a very useful accessory for use when it becomes necessary to insulate any large conducting body. For the table top of the stool prepare a board of sound dry mahogany, to measure about 12 in. by 10 in., and 1 in. or 1½ in. thick. It will be found to add greatly to the appearance of the stool if the edges of the board are moulded by means of a moulding plane. Exact measurements are not important, but the above size of top will be found very convenient for all ordinary purposes. When the top has been prepared, four wooden sockets will be required to receive the glass supporting legs, each of them measuring outside about 2 in. in diameter and 1½ in. thick, with an internal diameter of ⅝ in. As soon as the sockets are ready, they should be glued and secured to the under-side of the top, after which a 6 in. length of ¾ in. glass rod may be cemented into each one by means of electrical cement or a mixture of plaster of Paris and glue. Before cementing the glass rods into the sockets, it will be necessary to round off the lower ends of each one on a grindstone, afterwards levelling the stool carefully, and lastly polishing or varnishing the woodwork.

*The Electrified Head of Hair*, shown in Fig. 41, takes the form of a small wooden doll's head, which is cut off short at the neck, and mounted on a brass stem inserted through the neck well into the brain—that is to say, the cranium. A knife slit is now made across the middle of the head, and the slit having been filled with glue, a hank of coarse hair is folded over a piece of card and inserted in the groove. The stem of the rod is made to fit into a hole in a turned wooden base, on which the head may be supported when not in use. If the head is fixed into the prime conductor by means of the metal stem, and the machine is put in motion, it will cause the hair to stand on end, as if with fright.

*The Butterfly Net* of Professor Faraday, represented in Fig. 42, is a very useful appliance for demonstrating the diffusion of electricity over the surface of a conductor. A piece of tolerably stout brass wire is bent into the form of a ring about 4 in. in diameter, with about 2 in. of wire projecting in order to form a stem, which is now cemented into a 6 in. length of glass tube of small bore, in order to insulate it; after which the glass rod is cemented into a convenient turned wooden supporting base. Thus prepared, a piece of starched book muslin is now cut and sewn into the form of a small conical bag, about

8 in. in length, which is then sewn on to the brass ring of the supporting stand, being finally completed by attaching a couple of threads of silk (each about 12 in. in length) to the apex of the bag. These threads should be arranged one either way, one inside and the other outside, as will be seen by reference to Fig. 42.

*The Electrical Whirl*, shown in Fig. 43, will be found very useful for exhibiting the phenomena of repulsion. From a circular disc of very thin sheet brass, mark and cut a cross to the exact form of Fig. 44, being particular to see that the extreme points are quite sharp. A slight depression is now made in the exact centre of the metal in order to form the axis upon which it turns, and each arm should be slightly bent out of the flat near the centre, in the manner shown in Fig. 43. Thus prepared, the whirl may be supported on the point of a darning-needle fitted into the prime conductor of the machine. Upon the plate being put in motion it will cause the whirl to turn round on the point of the needle, in consequence of the electricity being rapidly given off from the points.

*The Electrical Inclined Plane* is a slight modification of the above, which forms a very interesting piece of apparatus of simple construction, as will be seen by reference to Fig. 45. A good sound piece of dry mahogany should be suitably planed and moulded to form a base 12 in. by 6 in., which is then mounted on four turned wooden feet, or the moulded supports previously described. A couple each of 4½ in. and 3 in. lengths of ½ in. glass rod are now cemented into small turned wooden sockets provided with short projecting pins, after which they are glued into holes bored for their reception by use of a suitable centre-bit at the four corners of the baseboard, the pillars being located in pairs at either end of the base. A hollow brass ball of fair size is now cemented to the upper end of each of the glass pillars in order to form a cap, and a couple of pieces of stout brass wire (perfectly straight) are then stretched from end to end of the base by being sprung into holes drilled for their reception in the inner faces of the brass balls. The whirl is cut from a piece of thin sheet brass, the same as before described, but in this instance it will require to be soldered to the centre of a perfectly straight piece of tolerably stout brass rod, the two outer ends of which should be provided with a small brass ball soldered to them. Upon the insulated glass knobs being connected with the machine, with the whirl arranged in the manner shown in Fig. 45, the latter will be seen to slowly roll up the inclined plane when the machine is put in motion.

*The Luminous Egg Stand*, which is illustrated in Fig. 46, forms a very useful and convenient support for eggs when a charge of electricity is passed through them. A sound dry mahogany base is first prepared to measure about 6 in. square, being provided with four supporting feet in the usual manner, after which a couple of 7½ in. lengths of wood, ½ in. square, are mortised into the stand on opposite sides, with a cross-bar of the same thickness over the top. A stout piece of wire, bent to the form of Fig. 47, is now tightly fitted into a hole bored for its reception in the middle of the cross-bar, a small brass knob being afterwards soft-soldered to the outside end of this. Another length of the same wire is now pointed at one end and then bent in the form of a ring at the other extremity, with a small loop near to the pointed end, similar to Fig. 48, and when ready, the point is driven securely into the baseboard immediately under the cross-bar. We shall now be ready for the supporting discs for the eggs, which may be sawn from a portion of a cigar-box cut to an oval form, with a 1½ in. circular opening in the centre of each, and a small slot the width of the uprights at either end, as shown in plan in Fig. 49. A small piece of wood is now nailed and glued to the inside of each upright in a suitable position to support the shelves at an equal distance from each other. The first egg put into the stand is supported on the lower connection with a shelf brought down over the top of the egg in order to retain it in position, after which the second and third eggs are arranged in a similar manner with the upper conducting-rod brought down on the top of the upper egg. A chain in connection with the outer coating of the jar or battery is now suspended from the loop of the lower conducting wire, with a director attached to the upper conducting stem by means of another length of chain. Upon the latter being brought in contact with the inner coating, the charge will pass through the eggs, which are rendered luminous during its passage, presenting a novel and beautiful appearance if the experiment is performed in a darkened room.

*The Apparatus for Firing Ether*, which is shown in Fig. 50, is very useful for demonstrating the inflammable effects of the discharge. For the base, a piece of sound dry mahogany, measuring about 7 in. by 5 in., is carefully planed up on the face and edges, and then mounted on four small supporting feet, after which a ¾ in. hole is bored through the wood at either end to receive the pins of the sockets which support the glass pillars. A 4 in. length of ½ in. glass rod is now cemented into a small turned wooden socket, which is provided with a short projecting pin, in order to allow of its being fitted and glued into one of the holes in the base. When this has been done, another 3 in. length of ½ in. glass rod is next cemented into a similar socket, which is then glued into the hole at the other end of the stand. A small metal saucer to contain the ether must now be attached to the upper end of the shorter glass pillar. For this purpose an ordinary small size mince-pie tin will be found to answer very well. A slight depression should be made in the centre of the under-side by means of a punch, in order to mark the path to be taken by the spark, after which a small piece of tin, bent in the form of a collar, of sufficient size to pass over the glass rod, should be soldered to the under-side of the saucer, thus forming a socket by which the latter may be cemented to the glass support. It will be necessary for a small hook to be soldered to the under-side of this collar, from which to suspend the conducting chain, or if preferred, the collar may be formed by bending a strip of tin round the glass rod and then punching a hole through the two ends, which are afterwards brought together and soldered, thus forming a socket similar in appearance to Fig. 51. The saucer being finished, the other glass rod must now be provided with a gas-fitter's brass cap, which is soldered to one end of a short length of stout brass rod, a small brass ball being affixed in a like manner to the other extremity, after which a brass hook is soldered to the back of the cap in order to make provision for the connecting chain, as will be seen by reference to Fig. 52. The cap, with the arm attached, is now cemented on to the end of the glass support, with the arm curved over in such a manner that the ball will come immediately over the depression in the ether saucer and within sparking distance. When in use, a piece of chain in connection with the outer coating of a charged Leyden jar is hooked on to the under-side of the saucer, and another length is suspended from the bent arm and attached to a director. Thus arranged, a few drops of ether are poured into the saucer at the last moment, and the ball of the director is rapidly brought in contact with the knob of the Leyden jar, which will thus cause a spark to pass and inflame the ether. The ether should be kept in a tightly corked bottle, and only poured into the saucer at the last moment, as it is extremely volatile.

*The Fire House*, illustrated in Fig. 53, is a very effective modification of the apparatus just described, in which the ether is enclosed within a small wooden representation of a house or cottage. A small model of a dwelling-house or shop is first procured from a toy dealer, and a brass knob and stem are then arranged to lead from the chimney-stack into the interior of the dwelling, where it terminates in another brass knob. A small shallow tin saucer, similar to the one used for the last piece of apparatus, is now soldered to a suitable length of brass rod, which is inserted in a hole in the side of the house, and then bent in the form of a hook outside, as will be understood by reference to Fig. 54, in which the front of the house has been removed, thus showing the interior arrangements. Thus prepared, a piece of cotton-wool, saturated with ether, is placed in the saucer, with the upper rod brought down over the saucer until within sparking distance. A short length of chain is now hung from the outside hook, and placed in contact with the outer coating of the Leyden battery, after which another length of chain is hooked on to the knob of the chimney and attached to the director. On the latter being placed in contact with the inner coating of the Leyden jar, it will cause a spark to pass which inflames the ether and produces the effect of a house on fire. The front, back, or one of the sides of the house must be removable, in order that access may be gained to the interior.

*The Thunder House*, shown in Fig. 55, is a similar piece of apparatus to the foregoing, but is employed for the purpose of illustrating the necessity for lightning conductors. In appearance the thunder house takes the form of a long, low building, with a factory chimney. For the two ends, plane up a couple of boards to measure 4 in. wide and about 6 in. in height from base to apex, and then prepare a couple more boards to form the sides, measuring about 9 in. by 4 in. each. Two more pieces will also be required for the sloping roof, each measuring 9 in. by 2¾ in. One of the long sides of each of the latter will now require to be bevelled on the inside, in order that the roof may join together close along the edge. Thus prepared, the building may be put together with glue and brads, with the two pieces forming the roof placed just below the edges of the sides and ends, thus forming a slight parapet, as shown in Fig. 55. The factory chimney is now turned in a lathe from a piece of sound dry mahogany, to measure, when complete, about 10 in. long and 1½ in. square at the base, tapering to 1 in. at the top. One side of the base must now be cut off at an angle, in order to adapt it to the slope of the roof, to which it is then glued near to the end of the building, in the position shown in the cut. Three or four small windows must now be painted along the sides of the building, and one of these,

immediatcly under the chimney, must be pierced by means of a fret- or keyhole saw. A small wooden shutter (A) is now made to fit loosely into the aperture thus formed in such a manner that a slight touch will cause it to fall out, the woodwork surrounding the aperture being bevelled inwards, so that the shutter will always fall outside. A length of brass wire is brought from the top of the chimney along the wall of the building until it reaches the open aperture, where it is continued in a diagonal line across the shutter, after which it is carried to the ground from the lower corner of the aperture, terminating in a small loop or hook. It should be affixed to the woodwork by means of short lengths of brass wire pointed at either end, and bent in the form of small horse-shoe staples, which are driven into the wood over the wire. The upper end of the lightning conductor, as it may be called, should terminate in a small brass ball, which may be soft-soldered to the end of the wire. When the building is ready for use, the shutter is pushed into the aperture of the window, with the diagonal wire in conducting communication with the remainder of the wire. The hook at the base of the building is now connected with the outer coating of the Leyden battery, and another similar chain is brought from the knob at the top of the chimney to a director. Upon contact being made in the usual manner, the charge will pass without disturbing the shutter, but if the experiment is repeated in the same manner, with the shutter placed in a reverse position, so that the contact is broken, it will cause the shutter to be violently thrown out.

The above form of apparatus may be made in a more simple form by cutting a piece of mahogany to represent the gable end of a house, and then mounting this in a vertical position on a substantial base. The upright board is now pierced with a couple of apertures, and fitted with shutters and conducting wires in precisely the same manner as above described.

*Shellac Varnish.*—As the ordinary glass supports used for electrical apparatus are almost invariably bad insulators, it becomes advisable to coat them with shellac varnish, which will effectually prevent the condensation of moisture upon the glass, owing to shellac being a first-class insulator. A useful shellac varnish for this purpose may be made by pouring bulk for bulk of methylated spirit on to shellac of good quality, which is placed in a tolerably warm place for about a day, being well shaken occasionally until dissolved, when it should be diluted with two or three times as much spirit, and then bottled ready for use. Ordinary shellac varnish, sold by shops, forms an excellent insulating varnish, provided that it is of good quality. It is also possible to obtain this in a bleached form, which will be found a great advantage when it is required for glass work. The varnish should be applied to the surface of the article previously warmed, otherwise, if it is applied to a cold surface, it will form a dull whitish film; but on the other hand, the glass should not be sufficiently hot to cause the varnish to bubble and hiss, or the glass will be apt to crack. The brush should only be drawn once across the surface whilst the varnish is moist, otherwise the previous coat will be dragged off.

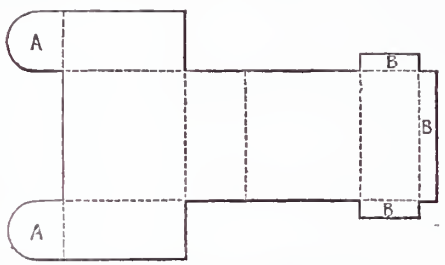
The illustrations to this paper are placed on a right-hand page, as in this position they are more convenient for reference when reading pages 658 and 659.

## HOW TO MAKE A CHEAP CAMERA CASE.

BY WALTER E. WOODBURY.

A few months ago I was badly in want of a case of some kind to hold my camera and slides when travelling, or when out photographing. On searching the various trade catalogues, I was much surprised at the high price charged for them; and so, after a little deliberation, I decided to attempt the construction of one myself. Having met with great success, I willingly give the particulars to readers of Work who may be placed in the same position. The case I have succeeded in making is wonderfully strong and durable, has a very good appearance, is remarkably light, and the cost is but a fraction of that charged by dealers.

We will first of all, then, suppose we have a camera and slides, and all the other necessary paraphernalia used by the amateur photographer when out photographing. This will include camera, slides, lens or lenses, diaphragms, and focussing cloth. The stand, or tripod, should be carried separately or in another case. The first operation, then, is to arrange the required articles on a table in the most convenient and compact form possible, and this done, to take the outside measurements and obtain the necessary



Flat Pattern of Cheap Camera Case.

length, breadth, and depth of the case to be made.

We next procure a stout sheet of millboard, free from dents or cracks. The size of the board required is, of course, according to the size of the case. The length of the board should be rather more than twice the depth of the case and three times the breadth added together, and the breadth of the board should slightly exceed the length of the case added to twice its breadth.

The accompanying diagram shows how the board is to be outlined and cut out. With a knowledge of the required breadth, length, and depth, it will not be difficult to mark this out in pencil, taking great care that all the measurements are exact and the right angles true. The two inner flaps, A, A, can be made any size and shape, to suit the fancy. The overlapping sides, B, B, B, of the lid should be about two inches. In making large-sized cases, when a millboard sufficiently large cannot be obtained, the lid can be made separately, and fixed on as afterwards described.

The diagram having been carefully drawn out, and every measurement ascertained to be correct, the shape is cut completely through the board where marked by the continuous lines, and then half-way only through the thickness of the board along the dotted lines marked in the diagram. These half-way cuts should be made carefully, endeavouring, as far as possible, to cut through the same distance all along; if parts be cut deep and others only slightly, the bend is uneven and unsightly.

Having made the necessary cut, the next operation is to bend the board along the dotted lines, and thus form the case and lid.

Next procure some long strips of calico or linen (broad tape will answer the purpose very well), and glue them along all the joints. It is advisable to get someone to hold the two sides together while you glue the strips along: by this means a tighter and neater joint is made. If additional strength is required, strips of the calico can be glued along the joints on the inside as well. The edges of the box and its lid should also have some of the cloth glued along them.

We have now our camera case in the rough. It can, of course, be used as it is, but its appearance is decidedly improved by a suitable covering. This will depend, of course, upon the fancy and pocket of the amateur case-maker. A good waterproof material is, perhaps, the most suitable. Bookbinders' cloth, leatherette, or thin leather can also be used. Imitation Russian leather will, of course, serve to give a handsome appearance to the article, and even this may be surpassed by using the real thing.

For a first attempt, however, I should not advise this extravagance, as a good waterproof cloth will be found to answer the purpose very well. A little care must be taken in covering the case with the material: all the joints and edges should be made to come in the least conspicuous parts.

It has already been stated that the lid can, if preferred, be made separate. This is often an advantage, as the constant opening and shutting will soon break through the millboard, and then the lid relies entirely for its support upon the material used for the outer covering. If the lid is made separate, and before covering the case be joined to the binding with a strip of thin leather, glued tightly half on to the lid and half to the back of the box, a much firmer job is made.

In order to prevent the inside of the case from scratching the polish of the camera, it is a very good plan to line it with a suitable lining. Green baize is very convenient for this purpose, as it is very soft and inexpensive. The lining can be glued on after the case is formed, or the baize can be glued to the back of the millboard before the shape is cut out. A suitable lining certainly gives a more finished appearance to the article, and will prevent damage to the camera and appliances.

If the case be of large dimensions, and is inclined to have an infirm appearance, it can be made much firmer and stronger by fixing in a wooden bottom. This should be done before lining by cutting a piece of board about a quarter of an inch thick to the requisite size, and gluing to the bottom of the case inside.

A few drugget tacks or ornamental coffin nails, driven into the bottom of the case outside, gives a finished appearance underneath, and also protects the material with which it is covered when the box is rested on the earth or other rough place.

The only thing we require now for our case is a handle whereby we can carry it, and a strap to fasten it. If required, a suitable lock can of course be purchased from any leather case manufacturers, and fitted on to it. The cheapest plan, however, is to purchase a cheap luggage or cloak strap. The handle of this is sewn or wired firmly to the centre of the lid of the case, and the two straps

pass round the case, fastening it tightly, and keeping the lid firmly closed.

Other improvements will, of course, suggest themselves. I have only endeavoured to give an idea how the thing can be done, and done with a suitable regard to cost. If the amateur likes to cover the case with real Russian leather, line it with plush or satin, and ornament the corners with silver plates, nothing I have said will prevent him. These hints as to the finish of the camera case, and the material and style with which and in which it may be finished, are merely thrown out to prevent any would-be maker of the appliance from thinking that there is any need for following a certain course with regard to the completion of the case, on the plea that such has been prescribed by the original maker, and that it is absolutely necessary on this account to follow it. On the contrary, it is better in this and all similar matters of finish and decoration for the maker to follow his own style, and to use such covering matter as may appear to him to be most suitable for the purpose, for by doing this, not only are different tastes better suited, but the pocket is also saved from needless depletion, which is of equal importance.

## "PASSE-PARTOUTS," AND OTHER DECORATIVE MATTERS.

BY PASQUIN.

A LARGE number of the readers of WORK are such as might be included in the same category as the writer—those whose artistic instincts are ahead of their means. To such, therefore, all "tips" or "wrinkles" which may conduce to the embellishment of the home are always welcome; and it is with a view to supplement whatever has already appeared in the pages of our favourite journal that the present suggestions are offered for the consideration of the readers of WORK; and as all such "tips" are the result of actual practice and experience, it is more than probable that there are many who will appreciate them.

First, then, let us consider the old-fashioned "passe-partout," which furnishes us with a cheap and easy method of preserving such pictures as are not thought worthy of the expense of a frame.

It is surprising what good results may be obtained from the most unpromising materials. As an instance, I will mention a common woodcut, representing Defregger's "Holy Family"—a modern work, but one of considerable merit. This woodcut occupied the centre of a sheet almanac issued as a Christmas supplement with a certain weekly newspaper some three or four years ago. It was not worthy of a frame, so I proceeded to treat it as follows:—Firstly, I "painted" or "tinted" it in water colours, keeping the tones subdued, and in keeping with the subject. Then I procured a piece of ordinary picture-glass, half an inch larger each way than the actual size of the print, on which I had already left a margin of about an inch, thus leaving 1½ in. from the edge of the glass to the edge of the picture. This glass cost me only 3d. Then I cut a piece of stout *glazed* brown paper to the exact size of the glass: this was to form the *back*. I had previously prepared several yards of paper tape, about three-quarters of an inch in width, and coated on one side with strong gum, which was allowed to dry thoroughly. Dextrine would, perhaps, have been preferable, but the gum was at hand, and the dextrine was not. Glue would have done, if thin and workable; but there would have been a risk of "messing" the work—a matter always worth guarding against. The glass, picture, and brown paper back were then bound neatly together at the edges with the paper tape, care being taken to get an equal grip *back* and *front*. When all was dry—a matter of half an hour—a piece of macramè string was knotted at each end, and a band of strong brown paper gummed over the ends. As the whole weight of the glass has to be borne by this cord, care should be taken to get a sound grip of the latter, for which purpose a strip was gummed *lengthwise* from top to bottom, thus putting all the strain upon it.

Now, as far as the structural arrangements go, the "passe-partout" is complete, so we proceed to the decorative or ornamental part. I procured a sheet of the coarsest sand- or glass-paper, which I cut up into strips of an inch and a half each, taking care to have *clean edges*. For this reason, I pencilled out the widths with a straight-edge, and used scissors to cut with in preference to a knife, which would probably, from the nature of the material, have caused more or less of a ragged outline. As the sheet was not long enough for the sides, each was composed of two pieces, the join being afterwards hidden, as you will see later on. The angles, of course, required to be mitred, which I managed by squaring a piece of cardboard, and cutting across diagonally. This then served as a template, other or more orthodox appliances not being at hand. The strips of sand-paper were then *glued* in place on the edges of the glass, thus covering the original binding paper or tape, as well as the margin of the picture, which had been left for the purpose. The mitres, as well as the joins in the sides, were then covered with diamond-shaped pieces of the same sand-paper, while over these again were glued smaller, but shield-shaped, pieces. When all was dry, the strips were painted over with lithographer's *gold* bronze, mixed to the consistency of cream with gum-water. A little care is here necessary to keep the gold clear of the glass. The diamond-shaped pieces were then bronzed, but with *copper* bronze, while the small shields were finally touched up with *silver*, and the job was complete.

These "passe-partouts" have now been hanging up for three years, and begin to show signs of requiring a second wash of bronze; otherwise, they are as sound and elegant as the day they were made.

For bedrooms, nurseries, and other such rooms, this method will be found very useful, as the work involved is nothing, while the materials required are within the reach of the poorest of us, costing, at the outside, only about 3d. per picture—the glass, of course, being the principal outlay. The bronzes are very cheap, and any lithographic printer will, for a few pence, supply you with sufficient of each to do many pictures.

But we have hitherto dealt with a picture with a plain back; what shall we do with those cut from the pages of the illustrated journals, and which have letterpress on the backs? Unpromising as such prints may appear to be, it is possible, with a little ingenuity, to convert them into "things of beauty," and thus "joys for ever." As an illustration of my method of treating such woodcuts, I may mention a portrait of Mary Queen of Scots, which appeared in the *Graphic* some time ago. This was a copy of an ancient painting, and as I could not command even a replica of the latter, I conceived the design of making one for myself. I ought to add that the woodcut had letterpress all over the back. I got a piece of glass the exact size of the print, which I first *cleaned* perfectly. This glass must be *chemically* clean, or the picture will probably blister or peel off long after you have expended time and labour upon it. Having cleaned it perfectly, then coat it thickly on one side with freshly-made boiled starch, which should be of the consistency of blancmange. Soak your print for a few seconds in clean water, and apply *face* to the glass. Then take a piece of parchment-paper, thoroughly soaked in water, and apply to the back of the print. Then, with a paper-knife or other smooth-edged tool, commence to work out, *from the centre* and towards the edges, *all* the starch. Go over this several times, watching—from the front—for air-bubbles, which must all be squeezed out carefully and perfectly. Then, when no more such bubbles are visible, and no more starch is to be worked out from between the picture and the glass, set the whole aside to dry. This may take a day or so: don't attempt to hurry it. When quite dry, take a piece of No. 2 glass-paper, and go carefully all over the back, taking care not to make holes, or to rub hard. It is a positive advantage to have the printing on the back, as by this you can judge of the effect of the glass-papering process. When all the letterpress is rubbed down, go more carefully, but continue the rubbing down as long as you dare. When you judge you have gone down thin enough, take a piece of No. 0, and finish *very* carefully. With the finer number a great deal more of the paper may be got away—the object being, of course, to leave only the thinnest film, with the print on the front of it. As soon as the paper is rubbed away as far as is admissible, mix a little castor-oil and turpentine, in equal parts, and rub this mixture well into the remaining film with the tips of the fingers. Do not fear to use too much, as it can be removed afterwards, when its work is done. The effect of this dressing is to render the print transparent, which it does instantaneously. Leave the print thus "in oil" all night, and next morning remove all superfluous mixture with a piece of cotton-wool. In this process use all necessary care to avoid injuring the transparent film, which, however, will bear a great deal of rough treatment on occasion. Your picture is now ready for painting—the final process.

"Oh!" some readers of WORK will say, "this is only the old crystoleum process, with which everyone is familiar, and which is long out of fashion." I beg pardon of such gentlemen—for whom, by the way, this article is not written. Did you ever know the crystoleum process applied to common woodcuts, with printing on the back? Again, *two* glasses are used in crystoleum, while I only advocate one, the picture supplying all the necessary detail, and the "painting"—for want of a better name—being of the most slap-dash order. Nevertheless, the result is not only pleasing, but really artistic, having all the softness and "velvety" appearance of a crystoleum painting.

Now as to the "painting." Mix first a good flesh tint, which may be arrived at by using zinc-white, chrome-yellow, and carmine in due proportions. Experiment with these until you get a flesh tint suitable for the subject in hand. Then with a very fine pencil put in the lips (carmine), the iris of the eyes (blue or brown, as the case may be),

the whites of the eyes, and all other fine or minute detail. Then with your flesh tint go *over all*, and afterwards put in your other tints or colours. As to the kind of colours to use, let them be *good* tube oils, but in the mixing use only turpentine—no *oil*—as you want your colours to dry quickly, while the glass furnishes more than sufficient glaze.

Pictures treated thus require no varnishing, a piece of soft paper being pressed over the back when the colours are finally dry, and the whole framed in the ordinary way. I have a series of four pictures thus produced, which were originally fac-similes of stained glass windows in the new Cardiff Castle. They are scenes from *As You Like It*, and were published as a supplement to the *Builder*. From this it may be seen that high-class productions are by no means essential.

Neither are woodcuts and prints the only materials available for the decoration of the impecunious man's home. The common plaster busts and images of the noble Italian refugee also lend themselves readily to artistic treatment—even the most crude and inchoate. What I once regarded as positive eyesores have, by judicious handling, become also "things of beauty," and—what is a still better test—money far in excess of their intrinsic value has been bidden for them. Take the well-known allegorical figures of Africa, Asia, etc., which I regard as most suitable for such manipulation. These are about 18 in. in height, and are sold at cheap rates by all statuaries. Go carefully over each one with a penknife and a fret-file or two, and remove all the "burr" left by the moulds. Of such excrescences there are usually more than enough to keep you employed for an evening or two. If the space between the upper and fore-arm and the head (as in the case of the "Basket of Flowers Boy") is left solid, bore this in the centre, and file carefully away to the proper outline, finishing, when necessary, with fine glass-paper. When all such false outlines are remedied, size the image with good strong size; thin glue answers very well. At this stage there is nothing very beautiful about the figure, which presents a uniformly streaky and dirty appearance. This, however, is of no consequence. Then mix your flesh tints, remembering that for "Africa" a different complexion is required to that which would be all right for "Europe." Experiment with white, browns, and yellows till you get it right. Then, when the flesh tints are put on, proceed to colour the garments, symbolical accessories, foliage (if any), etc.; but remember that each figure should be coloured "in keeping" with its subject. Any jewellery may be livened up with a little gold bronze, *applied dry* with a camel-hair pencil while the paint is still "tacky." In mixing the colours for this purpose, also, oil may be dispensed with for the most part, but carmine *always* requires a *little*, otherwise it dries *powdery*, and is liable to rub off if touched or dusted. No glaze is desirable upon statuary so treated; a dead surface is always preferable. Use the best artists' colours you can afford, and the result will agreeably surprise you. Some statuettes painted by the writer some five or six years ago are now as good as ever, and are still much admired.

These three methods of home decoration are, among others, drawn from the personal practice of the writer, and, besides furnishing his home with pleasing and durable ornaments, provided him with wholesome and fascinating employment during many a period of enforced idleness. Time of this kind, when employment even in the most trivial pursuits is welcomed as a boon, often falls to the lot of men and women, and hence the *raison d'être* of the instructions given above for the performance of work which people who are always busy might regard as useless and uninteresting.

**Front and Side Elevations of a Useful Bookcase for Small Books.**

## A USEFUL HANGING BOOKCASE FOR SMALL BOOKS.

DESIGNED BY S. J. SPELLER.

It will be in the remembrance of many readers of Work that in the course of the year 1890 prizes were offered for competition by Messrs. Cassell & Company, Limited, for three designs for bookcases specially adapted to hold the numerous volumes of Cassell's National Library. One of the competitors, Mr. S. J. Speller, of Frome, sent an alternative design of a more simple character than that from the same maker which won a prize. It was intended to publish this, as well as the prize-winning design, at the time, but the demands on space in Work were then so heavy, that it was determined to hold it over for some future occasion. An opportunity of presenting it to our readers until the present time has not hitherto offered itself, and it is now given, partly on the principle that it is better to do a thing late than to leave it undone altogether, and partly because a simple but, at the same time, a highly attractive design of this kind is sure to find favour with many, and be made by them either for the adornment of their own homes, or as a welcome gift to add to the embellishments of the home of a friend.

The bookcase may be made in any material, from soft pine to hard oak, according to the preference of the maker; but if it be intended to enrich the work with carving as shown in the design, hard wood should be used. Moreover, pine is by no means a wood suitable for carving, and the workman might come to grief in endeavouring to copy the ornamentation at top and bottom in any soft material. Therefore, all points considered, it may be taken that oak is by far the best timber to use in making a set of hanging bookshelves, such as those now under consideration. The total height of the bookcase from top to bottom is, as shown in the illustration, 4 ft. 3 in., and dividing out and marking this as a scale, the proportions of other parts can be easily ascertained by actual measurement. It may be said with reference to sizes of parts that, in order to give due effect to the carved work on the front edges of the sides, the sides themselves should not be less than $1\frac{1}{4}$ in. in thickness, or thereabouts; the depth of the panels, as shown in the side elevation to the right, from $\frac{1}{4}$ in. to $\frac{3}{8}$ in. below the original surface; and the shelves about $\frac{5}{8}$ in. thick. The ornamental work at the top and bottom may be pierced as shown in the front elevation to the left, or boldly carved out of the solid and the ground stamped. The sides may be got out of 1 in. stuff if preferred, but if the edges are carved according to the design, they will not present as effective an appearance as they will when worked in thicker stuff. The sides should be further rebated to take back, and grooved on the inner surface of each to take the shelves.

It has been said that the bookshelves are intended for the reception of very small volumes—namely, those of Cassell's National Library, a new issue of which, with various additions, is now in progress. There is no reason, however, why bookshelves on this pattern should not be made to take larger volumes; and, if this be desired, all that has to be done is to make the sides of suitable length, and to make the width of the space between shelf and shelf proportionate to the height of the books each shelf is intended to hold. The edges of the shelves may be simply carved, the leather, as shown in the illustration, being inserted in a groove made in the under part of the shelf a short distance from the edge, and held in place by a slip of wood which fills the remainder of the groove. Those who cannot accomplish the grooving may attain the appearance by pulling the leather along the edge of the shelf—by gluing is the best mode—and then putting on a bead of the same thickness as the shelf outside the leather.

## A COMFORTABLE ARM-CHAIR.

BY H. A. MILES.

INTRODUCTORY REMARKS—MATERIAL AND UPHOLSTERY—ECONOMICAL USE OF MATERIAL—FRAMING—THICKNESSING—CHOICE OF MATERIALS DETERMINES METHOD OF CONSTRUCTION—HOW TO CUT OUT PIECES OF FRAMING—CONCLUDING REMARKS.

*Introductory Remarks.*—Every house is usually furnished with an arm-chair, or so-called easy chair, but how seldom is it a seat into which a tired person could sink and drop off to sleep! As a rule, the seat is so deep that, unless the owner is possessed of exceptionally long understandings, he would be unable to recline against the back without raising his feet from the floor; then how frequently the back is either too upright or too sloping, too high or too low, either propping the head up in the comfortable manner of a photographer's rest, or suffering it to hang over in a manner strongly suggestive of a barber's shop.

To obtain the maximum of comfort, of course, a chair should be made of a size suitable for the person who will occupy it; but a happy medium may be struck, and a chair produced of such a design that most persons would be able to indulge in a post-prandial forty winks in ease and comfort.

Such a chair it was my good fortune to come across during my recent wanderings in the country, and as I never lose an opportunity of making hay while the sun shines, I at once pulled out my rule and made a rough dimensioned sketch of the chair on the spot, taking the opportunity afforded by the first showery afternoon to try and introduce it to my readers.

*Material and Upholstery.*—The material used was English oak, upholstered in morocco.

A side elevation is shown in Fig. 1, a back view in Fig. 2, while Fig. 3 shows the most economical method of cutting out the material.

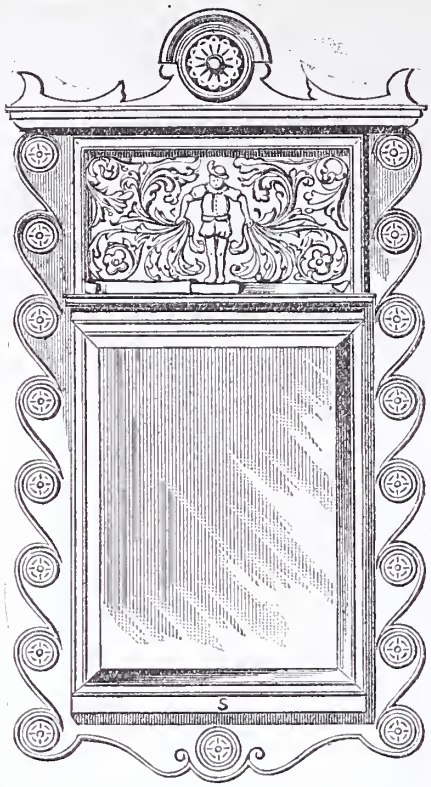

Fig. 1.—Wall Mirror in Brass Repoussé Work.

*Framing.*—The thickness of the framing is about $1\frac{3}{8}$ in., and the portions round the seat and back are thicknessed up with $\frac{3}{4}$ in. deal on which to fasten the upholstery. It would be preferable to mortise and tenon the cross pieces, A (Fig. 3), into the side pieces, B (Fig. 3), before gluing and screwing the latter to the side framing, as the tenons can then be wedged up.

*Choice of Material determines Method of Construction.*—If oak is considered too expensive, good yellow deal or pitch-pine would make a very neat-looking piece of furniture. If pitch-pine or any other soft wood be used, it would be advisable to add a rail between the front legs, as shown in Figs. 1 and 2 by dotted lines, G.

*How to cut out Pieces of Framing.*—The entire set of pieces are in duplicate, so that if two pieces of wood be fastened together and the curves drawn on one side, all can be cut out together, either by a frame-saw, used by hand, or preferably by means of a band-saw.

*Concluding Remarks.*—I have merely given a rough idea of the chair, without entering into small details of construction, and for this reason have given dimensions from centre to centre, so that the proportions of the parts may be modified to suit the strength of the material used without materially altering the design.

I can safely promise anyone who has the necessary ability to make it that he will have to take a long journey if he wishes to find a more comfortable seat.

## A WALL MIRROR, WITH BRASS ORNAMENTS IN REPOUSSÉ WORK.

BY ROBERT COXON.

THIS design for a wall mirror will be found to produce an effective piece of work if carefully carried out. It is designed more especially to suit the brass frieze, which is of an original character in a quaint old

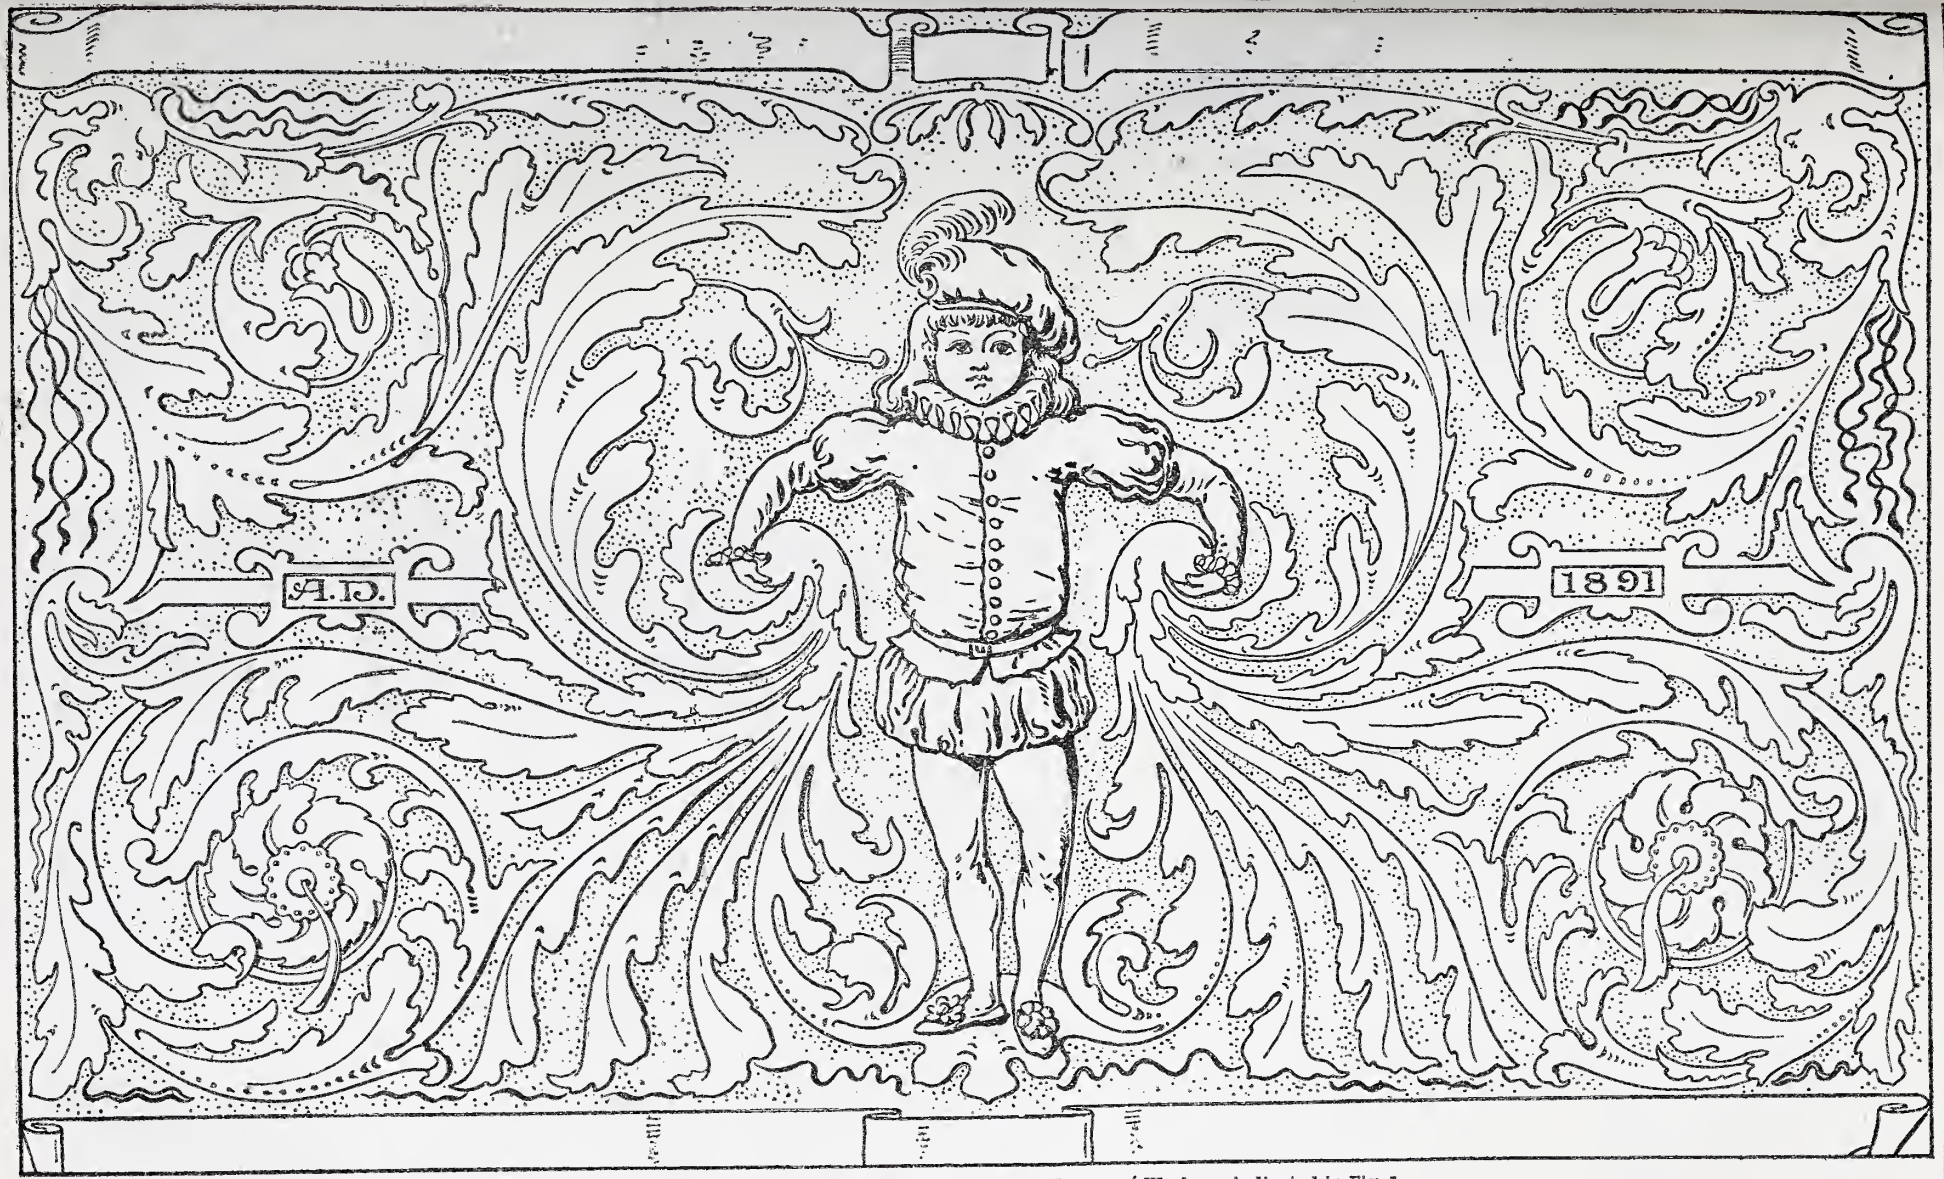

Fig. 2.—Full-size Design for Ornamental Panel in Brass Repoussé Work, as indicated in Fig. 1.

English style, and would form a charming piece of decoration for amateur repoussé workers; the woodwork best suited being ebony or a hard wood stained or ebonised, but the characteristic of the drawing would lend itself to reproduction by wood-carver's tools, and those of artistic tendencies would find it a good subject for execution in painting or gesso work. Those of our readers requiring a more simple method would find little difficulty in reproducing the design in burnt wood engraving, a simple but effective art which is much followed just now.

If carried out in brass repoussé work, care should be taken to carefully trace the design, as much of the crisp effect is lost when this is not uniformly correct. The rosettes at the frame scroll work could be purchased at a moderate cost from any upholsterer's furnisher, and might be equally effective a little smaller than shown, but not to exceed 1½ in. in diameter. The bevelled glass is mounted in the frame with a ¾ in. moulding. The shelf s at bottom of the glass would be about 3 in. broad. This shelf, as will be seen by looking for it in Fig. 1 in the opposite page, is shown only by its edge, Fig. 1 being intended to show the mirror complete, and the position of the ornamental panel in brass repoussé work at the top (as shown full size above in Fig. 2), and the enrichments of the frame.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Setting Out.

We have looked at the setting out for mortise and tenon and for dovetail joints. There is a further hint to be given on dovetails—that is, to avoid too great an angle in the spreading of the dovetail. The common idea is that the greater the difference between the size of the pins at the outer surface, where they are small, and the inner surface, where they are large, the better. Now it is not so. It only needs a slight difference, depending, of course, upon the thickness of the material what that difference is to be. Look at some good cabinet-work, and copy the angles and proportions of dovetails and pins.

Dowelled joints may be set out in similar manner—that is, with square and gauge; but if many joints are to be made, a template, which can be made of thin wood, metal, or even cardboard, will be of service in saving time, the centres of the dowels being pricked through the template, and, by its aid, to the work itself. Care must be taken in the use of the template that it is not turned, but used from the proper edge in every instance. It is to be remembered in setting out that every detail should be known and provided for at the beginning, otherwise mistakes will arise.

The professional way of setting out is by means of a rod, as it is called, which is a strip of wood as long as the work, on which all the lines are marked on one side, measured lengthways, and usually on the other side, or on a separate rod measured *across* the length. This answers the purpose as well as a full-size drawing to a workman; but by all means retain the habit of making scale drawings of your work, if you have such a desirable habit; if not, attain to it as soon as possible. The time when the workman shall be an *artificer* in its true sense will be brought nearer when the workman is in the habit of drawing to scale plans, elevations, and sections of his work. It will cultivate the ability to see the end from the beginning, which is needful if a working drawing is to be entitled to the name of a design.

The setting out *is* the difficulty of the beginner, but the difficulty disappears as he is learning to draw to scale. There is no plan of learning so good or so rapid and effective, and for the amateur, for whom these lessons are intended, it is absolutely necessary that he should learn to 'do whatever he wishes by himself, availing himself, of course, of any convenience of prepared material, but making the article suitable to its intended purpose, and to show its suitability obviously, yet pleasing the beholder by the oneness of the whole thing.

On the subject of setting out, I must remind the reader that he must, in most cases, be guided by the capacity of his tool-chest. It is of no use to gauge for a tenon of any other size than one we have a chisel suitable for, or to mark dovetailing smaller than any chisels we have in stock, or dowels of a size we have no bits to bore, and so on. On the other hand, halving, dovetail halving, housing, and bridle-joints are not so very imperative in demanding special tools, or tools of a special size. The best thing that the amateur workman can do when he finds that he wants a chisel or bit of a size he has not got, is to buy it. Tools are always useful, and, in this case as well as others, store is no sore.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 99.—Rogers' Improved Attachment for Lathes.

Some of my readers may, perhaps, remember that in Vol. II., page 583, of Work, otherwise No. 88, an illustration and description were given by a correspondent of an improved shaping attachment for lathes. In the illustrations given below, a modified form of shaping attachment, similar, in some respects, to that to which attention has just been directed, is shown. This form, which is known as "Rogers' Improved Attachment for Lathes," has been designed by Mr. F. M. Rogers, Fellow of the Chemical Society and Associate of the Society of Telegraph Engineers and Electricians, to meet the demand for a tool of this class, capable of working on a slight, single-geared treadle lathe such as is generally used by amateurs and light metal-workers. The appliance itself, in its complete state, is shown in Fig. 1. The stroke is fixed, and is determined by the throw of the eccentric sheave shown in Fig. 2, which is screwed direct to the nose of the mandrel, and travels in the grooved path upon the back of the face-plate, thereby imparting a noiseless reciprocating motion to it. The attachment is made to suit lathes of different sizes, but the stroke in the size shown in Fig. 1, which is the size adapted to a 4 in. centre lathe, is about 2 in., which enables one hundred and twenty cuts per minute to be taken with ease in brass or gun-metal. The V packing-strips are of gun-metal, and an adjustment is provided for taking up wear. When fitted with

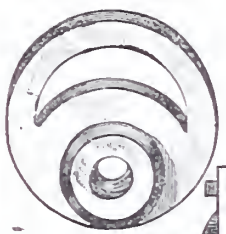

Fig. 2. Eccentric Sheave.

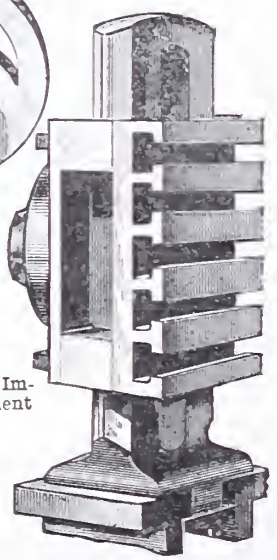

Fig. 1. — Rogers' Improved Attachment for Lathes.

a parallel vice, this little tool will rapidly shape odd pieces of metal which otherwise would have to be filed up. Larger work is bolted to the face-plate. The slide-rest can be operated by hand or by self-acting motion. In addition to the shaping of metal, planing can also be effected by the aid of this appliance, key-grooves cut, and a variety of other tooling work accomplished with accuracy and rapidity, provided the speed is suitably proportioned to the work. Light metal workers will find their work much facilitated by supplying themselves with a punch and pair of shearing-blades for cropping sheets or plates and roughing out material. These, it is almost needless to say, can be procured with the attachment, which, when in use, has its standard bolted to the bed of the lathe. This appliance is well worthy the attention of turners, especially amateurs who have an inclination for metal work. It appears to have been carefully designed with an especial view to the general requirements of this class of workmen, and to be turned out with equal care, accuracy, and finish.

### 100.—Kerr's Improved Workman's Drinking Flask.

The ordinary oval tin bottle or flask generally used by workmen, stoppered by a cork, and unprovided with any means by which its contents may be swallowed other than by that of pouring

**Kerr's Improved Workman's Drinking Flask with Cone Cover (A); with Cone Cover inverted and screwed on Flask (B); Cone Cover inverted (C) as Cup; Milled Stopper (D); Section of Top of Flask (E).**

them into the month through the orifice at the top, must certainly give place to the neat and well-appointed drinking flask known as "Kerr's Improved Workman's Drinking Flask," invented and recently patented by Mr. D. W. Kerr, plumber to the Dumfries Gas Commission. This flask, when not in use, or when filled with tea or coffee, presents the appearance shown at A in the accompanying illustration. In this it looks like an ordinary round bottle with a cone-shaped top and a milled cap or cover, which screws on or off at pleasure, in place of the ordinary cork, with a handle affixed to the upper part by which the can may be slung or carried in the hand. A closer examination, however, reveals the fact that the cone-shaped cover screws off, and shows that underneath it is another top fixed to the bottom, also cone-shaped but handleless, as may be seen at B. In the top of this is inserted a short brass cylinder with a screw-thread cut within, as shown in section at E. The cone-shaped cup or cover, when removed, appears as shown at C; and when it is turned upside down in this position, the orifice that is now at the bottom being closed by the milled cap or cover—shown separately at D—can be used as a drinking cup. But it has yet another use than this, for when the milled cup is removed, the cover or cup can be screwed into the mouth of the flask and thus act as a funnel or filler when pouring in hot tea or coffee. When heating tea or any other liquid in an ordinary flask, it is necessary to remove the cork or top screw to allow the steam that is generated to escape, but with this improved flask a mere turn of the cover suffices to afford an outlet for the steam through a small hole in the screw part shown at E. The steam is directed downwards between the top of the flask and the cover, and cannot blow upwards so as to scald hands or face. The movable cup, moreover, speedily cools, and may be used for drinking purposes as soon as the liquid within the flask is hot enough. The flask is made in three sizes—namely, 1 pint, 1½ pints, and 1 quart—and will be found as useful at picnics and to sportsmen and tourists as to working men.

The Editor.

## SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

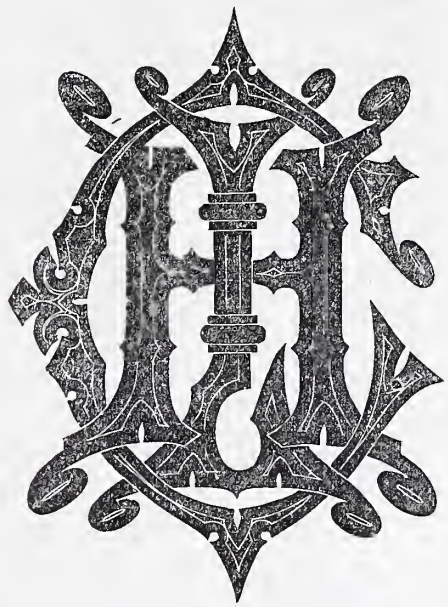
**Subjects for Royal Engineers.**—J. B. (*Salford*).—The Royal Military College, Sandhurst, is devoted to the instruction of young officers, both for cavalry and infantry, after they have passed the examination for commissions, and before they are appointed to regiments. The course lasts a year, and the instruction is confined to purely military subjects—fortification, military sketching, tactics, military law, correspondence, and accounts. At the conclusion of the course, the students are required to pass an examination in these subjects, and their commissions are dated according to the result; those in the first class being antedated two years; those in the second, twelve months; and those in the third dating from day of examination. You would have to enter as a candidate at an open competitive examination. The limits of age are seventeen to twenty, except in the case of university students and one or two other exceptions. The examinations are held under the Civil Service Commissioners. The successful candidates receive commissions as sub-lieutenants, and then go to Sandhurst. The Royal Military Academy at Woolwich is the training school for Royal Engineers. The course of instruction is mainly scientific, mathematics being one of the chief subjects—and also professional. Successful candidates for the Engineers receive appointments, and may go to Chatham, or be employed on works or buildings.—J.

**Piano Tuning.**—JACKSON.—A very concise and clear little book of instructions to pianoforte tuners is "The Tuner's Guide," by Abadie, price 6d., published by Lafleur, of Green Street, Leicester Square. We know of no work on the voicing of harmoniums and American organs; though we have an impression that Messrs. Metzler, of Great Marlborough Street, used to publish a little *brochure* on the subject.—G.

**Harp.**—CONSTANT READER.—It is scarcely possible, within the limits assigned to inquirers in this column, to give full working details of the construction of a harp. Here, however, are some of the main features, which will enable our correspondent to set to work. A harp consists of three parts: 1, a column; 2, a body, shaped like a boat and held in shape by ribs; 3, the neck. The wood usually employed is maple for the pole, body, and neck; and for the sounding-board or belly, a special kind of pine-wood—obtained principally from the forests of Bohemia and Switzerland—which possesses a high degree of sensitiveness to musical vibrations. The same description of wood has been and is still used for the sound-boards of every description of musical instrument—violins, 'cellos and string basses, guitars, zithers, and pianos. The only metal work employed is the ring in which the pole is held where it joins the body at the base or thick end, and the wrest-pins or tuning-pins. The distance between each two strings is determined merely by the thickness of the player's fingers. The pole is made separately, of course; the body separately, the neck separately. The neck is glued permanently into the head; but the body is not permanently fixed—it is held in position by the tension of the strings on dowels at the treble end, and by the ring already referred to at the base. Seven strings complete the octave, so that a 5-octave harp would consist of thirty-five strings; and our amateur harp-builder would probably add another string, so as to make the harp begin and end on the same note. Should he wish for a few extra semi-tones, to enable him to wander from the key in which he starts, he must procure some fiddle-pegs, and insert them in the neck in such a way that, when turned from the vertical to the horizontal, the peg shall, by pressure on the string, shorten it by about one-sixteenth of its length—*i.e.*, so that it will arrest the vibrations at a point about one-sixteenth short of its total length. The shortest string, E, on Erard's 43-string 6-octave harp is 3 in. long, and the longest, G, is 58 in. There is a double-action harp which gives three different sounds from each string; but, should our correspondent's ambition have contemplated the making of one of these, there is only one way to accomplish it—viz., to buy one, take it to pieces, see how it is made, and copy it.—G.

**Pantograph.**—JOINT.—The pantograph has had more than one allusion made to it in back numbers: see p. 669, Vol. I. (No. 42), for an illustration and a description of it. Do not concern yourself with making one. At a price not exceeding sixpence one may be bought, which would afford you every detail necessary, if you contemplate making quantities for sale; or would answer its destined purpose much better, probably, than a home-made one would. Any artists' colourman would obtain you one.—J. S.

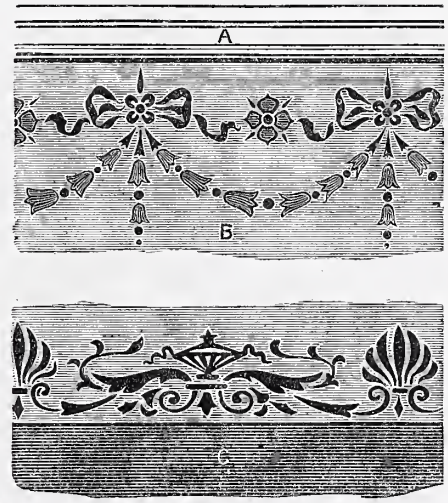
**Monogram for Inlaying.**—C. L. H. (*Reading*).—In print this monogram is decidedly bold, distinct, and effective; nevertheless, C. L. H. could render it much more so if—when reproducing for inlay—he composed each initial of a different-coloured wood; or, if a subdued and delicate effect be preferred, three *shades* of any particular colour could be employed—say, for instance, dark, medium, and light yellows. These would certainly make a rich and pleasing combination. Should our correspondent



C. L. H. Monogram for Inlaying.

possess sufficient patience and skill, he could even introduce two colours or shades in each letter, taking the white lines on the lettering as indicating the middle insertions. This treatment would, of course, necessitate great care; but, if neatly executed, the result would amply repay the time and trouble expended. Before piercing, C. L. H. would, doubtless, profit by noting the hints contained in previous replies to E. M. N. and others which have appeared in WORK.—A. C.

**Paint, To Harmonise.**—J. K. B. (*Manchester*).—For a bedroom treated in "light pink," I think your safest colour for a frieze stencil would be a dark shade of the wall colour. If you are going to put a dado of colour, then it would be well to make up this, using the same stainers as for the pink, but also adding umber, in order to keep the red under control. Then use the dado colour for the frieze. I must confess that I don't admire *both* dado and frieze in a bedroom; but if the room is of a good height, and the customer desires it, well and good.



A, Cornice; B, Frieze; C, Dado.

The frieze stencil and border I have sketched here to half scale would look well in one colour. I should also advise stencilling the dado border with the dado colour, and then running a base-line to the border in black, or very deep bronze-green. Sage, or very quiet yellow-green, is the only other tone likely to suit with your wall colour and for a bedroom. I think shades of all one warm tone will be best. Mind your stencil colour is strong enough. Dry a piece upon the pink before use.—DECORATOR.

**Combined Bench and Tool Chest.**—MANCUNIAM'S address is unknown to us. If you require more than the full details already given to you on p. 524, No. 33 of WORK, please write definitely through "Shop."

**Bending Brass Tube.**—A PUZZLED ONE.—I expect that what you call brass tube is in reality what is known in the trade as brass cased tube—that is, an iron tube with a thin casing of brass. If this is the case, I advise you not to try to bend it to an angle, but to cut and mitre it. Bend a piece of solid round iron to the angle of the window; let it be about 3 in. long each way, and let this fit tightly into the cased tube and form a connecting piece. You can solder the mitre-joint or not; if you make a true and good fit, it is hardly necessary. I have fitted up a good many in this way with satisfaction. —R. A.

**Soldering Hoops on Churns.**—E. T. (*Broadway*).—It is decidedly best to take the hoops off, and re-tin the part that comes in contact with the churn. To get over the difficulty of keeping the hoop hot whilst you solder round, you should use a gas blowpipe to warm it as you go along. With regard to learning the churn-making trade, you ask if you would have to serve a time and pay a premium. If you know anything of tin-work in general, you could get a job without either paying a premium or serving a time; but it would be as an improver, and at a lower wage than you would get in any branch that you were familiar with.—R. A.

**Battery for Lighting Model Church.**—VEGA. —It may interest you to know that I have a small single fluid bichromate battery of four cells, contained in a case about 6 in. by 6 in. by 6 in., with lifting arrangement for immersing elements as required, which brilliantly lights a 2½ c.-p. incandescent lamp. If you would like a description, I will give it you, with the Editor's permission.—H. E.

**Dulcimer.**—W. M. C. (*London*).—All the information you require upon this subject will be found in the following numbers of WORK: 31, 38, 41.

**Imitation Tortoiseshell.**—R. G. H. (*Birmingham*).—The address of the Xylonite Company is Fore Street Avenue, London, E.C.; and besides being makers of imitation tortoiseshell, they also turn out some capital imitations of ivory, coral, lapis, etc., in xylonite. There is an article on xylonite on p. 787, Vol. II. of WORK (No. 101), in which the writer gives some useful information; but not on polishing. The firm will reply to you if a stamped directed envelope is sent; but meanwhile a good surface can be obtained if it is treated as tortoiseshell is—viz., smoothed with a file and glass-paper if necessary, then with fine powdered pumice and water, and finally with clean damp whiting, finishing up by rubbing with dry whiting and the palm of the hand. The pumice and damp whiting is applied by means of a piece of soft cloth, unless you have a lathe, when a dolly or bob might advantageously be used for it. If you look through the indexes of the two volumes of WORK, you will find several answers on polishing horn and tortoiseshell, which may help you. In this case where you say you want to re-polish some handles that have gone dull, fine whiting ought to be sufficient when added to a good lot of rubbing.—H. S. G.

**Gold Lace.**—L. N. (*Oldham*).—To clean this, refer to a reply on p. 223, Vol. II. of WORK (No. 66), which you can order through your newsagent for 1d. This is always an unsatisfactory job, and when you get your new regalia, take the greatest care of it by carefully drying it in a soft rag if by any means it gets wet. Keep it out of the way of smoke, etc., in a tight-fitting box, and do not let any rubber rings be used to fasten the box, or even kept near it, for silver tarnishes very quickly even when gilt, as it is in your case. Gold lace, so called, is, I believe, never of gold, but either silver or copper wire electro-gilt.—H. S. G.

**Embossing on Glass.**—A ZINC-WORKER.—You say that you "have tried fluoric acid for embossing on glass with little or no result, as it bites into the glass, but leaves a clear ground." Now, this is just how it should act, and diluting the acid would certainly not produce the ground glass appearance. Where you have made a mistake is in using fluoric acid instead of fluoric acid *gas*. To make this, mix finely powdered fluor-spar (calcium fluoride), three parts, and sulphuric acid, two parts; put in a leaden dish; lay the glass to be etched, with the design prepared and drawn in the same way as for the liquid process, over the dish, and apply a gentle heat; the gas is then given off, and the glass is etched with a ground appearance. This operation should be conducted in the open air, as the fumes are highly dangerous to health. If you do not care to use this method, the only other way is to proceed as you have been doing, and afterwards roughening the design with emery of different degrees of fineness; but you would find this rather a risky proceeding, and the results would not be as good.—W. E. D., JNR.

**Sign-Writers' Alphabets.**—W. R. W. (*Fulham*). —I cannot understand that you could not obtain what you desire from Brodie & Middleton. Nevertheless, you will find what you want in the following books, published by Crosby Lockwood and Co., Stationers' Hall Court, E.C.: "Ornamental Alphabets, Ancient and Mediæval," by F. Delamotte, cloth, price 4s.; or, "Examples of Modern

Alphabets, Plain and Ornamental"; or, "Mediæval Alphabets and Initials for Illuminators." There are also several sheets of alphabets, etc., in "The Art and Craft of Sign-Writing," published by W. G. Sutherland, St. Ann Street, Manchester.—H. L. B.

**Incubator.**—W. E. T. (*Burton-on-Trent*).—Probably before you see this the wished-for article on a hot air incubator will have appeared, it being already in type. The Rearer article will follow shortly. For your other queries, get your bookseller to procure indexes of Vols. I. and II., and look up what you want. All back numbers can be obtained at the usual price. For rates of Sale and Exchange column, consult the current or any issue. —LEGHORN.

**Gesso Work.**—SCULPTOR.—Materials for gesso work can be obtained from the Society of Artists, 53, New Bond Street, W. Directions for the use of the composition are given on the tins. To commence the art, gesso composition is all-sufficient; but if large pieces of work are in hand, artists generally make their own gesso of the finest possible plaster of Paris, rubbed down with water to a batter, and glue or resin added.—C.

**Glaziers' Diamonds.**—A. R. (*Askett, Bucks*).—Evidently the address you want is Messrs. James Nicholson & Co., Glass, Lead, Varnish, etc., Merchants, 214, Upper Thames Street, E.C. If it is not, then you had better write again, when no doubt our obliging Editor will insert your request. As you may not be able to wait so long, and in case the above is not the correct one, I here give two other addresses of makers of glaziers' diamonds—viz., Messrs. Sharratt & Newth, 43 and 44, Percival Street, Clerkenwell, and Mr. Fred Biddle, 4, Percival Street.—H. S. G.

**Milling Machines.**—F. G. (*Erith*).—The best book on this subject is "The Mechanician and Constructor," by Cameron Knight, published by Spon at 18s. But there is nothing in it on milling machines, neither will you be able to get any work on that subject. Any specific queries on this subject would, however, be answered in WORK.—J.

**Axle.**—G. S. (*Hollinwood*).—Axle-trees are only fitted to mail or collinge axles, and there is no altering the pitch; but when the common arms are used, they are set into a bed, and to get the right pitch so as to allow the wheels to knock and run sweet, we do what is commonly known amongst wheelers as "gaiting" them. First get the bed planed straight and true, then set the arms at each end of the bed. We will suppose that we are fixing the arms in the bed for the hind wheels, 4 ft. high, cart fashion. We therefore get the straight-edge and place it across the felloes at the front of the wheel, then measure the space between the face of the spoke on the nave and the straight-edge, which we will suppose to be 2 in.; keep the straight-edge in this position and measure the distance at the other end of the same spoke near the felloe. Whatever this measurement may be, it must be deducted from the first measurement. If the latter was 1 in., it therefore leaves 1. The secret of gaiting a wheel lies in allowing a small ¼ in. hook from the string to the shoulder of the arm off every inch we measure from the disb of the wheel. Therefore, in this case it will be a ¼ in. hook, the arms being let into the bed until this measurement is attained.—W. P.

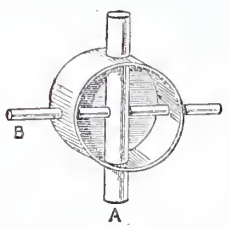
**Filling.**—W. C. (*Peterhead*).—Patent filling is now too well known amongst painters, having superseded ochre, formerly used for filling up. The advantage of the patent filling over ochre is that it makes a more solid ground to work upon, besides requiring less labour in rubbing down. The following is the recipe for mixing the filling:—Mix 4 lbs. of patent filling and 2 lbs. of best white tub lead into a paste with turps; place into a can, and thin down with 1 pint of turps, ½ pint of gold size, and ½ pint of jobbing carriage varnish. When it is well mixed up it is ready for use, and can have from one to two coats daily. The carriage must only have this filling applied upon those parts which show, and should have a couple of coats of lead colour before the filling is applied, the last coat being stained with Indian red or rose-pink, to guide you when rubbing down. When the last coat is put on, leave for a couple of days to dry, and when rubbed down let it stand for another couple of days for the water to evaporate out of the filling. When thoroughly dry, give it a coat of lead colour and proceed painting the carriage.—W. P.

**Weight of Copper.**—AMATEUR.—A square foot of copper ¼ in. thick weighs 5·75 lbs.; a square foot, ⅛ in. thick, 2·87 lbs. The method of making the port-holes in a model cylinder depends on the size of the cylinder. Anything over about ⅝ in. or ¾ in. bore is *cored*, the shape of the core-box being governed by circumstances; smaller cylinders have their ports drilled.—J.

**Getting Gold off from Gilt Buttons.**—J. K. (*Mile End*).—String the buttons on a platinum wire, immerse them as an anode in a solution composed of one part of potassium cyanide in ten parts of water, and pass a current through the solution from a strong battery to a strip of gold forming the negative pole in the solution, until all the gold is dissolved off the buttons. Then evaporate all the water from the solution, and dry and fuse the salt in a plumbago crucible with an equal bulk of dry carbonate of soda. The crucible must be kept at a white heat for several minutes. The button of metal thus obtained will be an alloy of gold with brass.—G. E. B.

**Silvered Glass.**—J. B. (*Doncaster*).—As I understand your questions, you wish to know where you can buy a small quantity of silvered glass in Doncaster; also if there is a firm in Hull. (1) I do not know where you can get silvered glass in Doncaster; but nearly any cabinet-maker will supply an amateur; and although, perhaps, you may have to pay a slightly higher price than if you bought of a manufacturer, still you can very often get better served, as large dealers do not care to be bothered with very small orders. (2) As regards Hull, I think you will be well served if you apply to Messrs. Primrose & Co., Glass Merchants, Hull. I may say it is very near the Paragon Station—in fact, just outside. To fill up cracks in oak, try resin and beeswax, melted together and tinted to proper colour with burnt umber and Dutch pink: or, if you prefer it, putty, tinted to match.—W. E. D.

**Winter Electrical Machine (Prime Conductor and Glass Rod).**—DRAUGHTSMAN.—You ask for the address of a firm supplying brass bedstead knobs suitable for the ball of the prime conductor of the above-named machine. Messrs. Noyes & Co., Old Street, St. Luke's, London, could supply you with brass bedstead knobs; but the largest size kept in stock is 2½ in. in diameter, which is scarcely large enough for the purpose, as it would look out of proportion to the Winter ring attachment. Knobs of the size required are to be obtained in Curtain Road; but I fear that you would have to purchase the bedstead as well, which would make it come expensive. If you state your wants to Prof. Caplatzi, The Science Exchange, Chenies Street, Tottenham Court Road, London, I believe that he will be able to supply you with a brass ball made specially for the conductor of this class of machine. Should you experience any difficulty in obtaining a brass ball of the diameter needed, you could employ, as a makeshift, a brass box in place of the ball. This should be made from a 2½ in. length of brass tubing, 3½ in. in diameter, with a disc of the same metal neatly soldered on to the open ends of the tube. A 6 in. length of ¾ in. tube is now put through the box from side to side, as shown at A in the accompanying diagram; and an 8 in. length of stout ¾ in. tube is soldered crosswise through the box, as shown at B, the tube being inserted through holes drilled in the centre of the larger tube. Finally, a small quantity of soft solder is run all round the junctions of the tubes, care being taken not to plaster the solder about, as this would mar the appearance of the whole work. The solder should be cut up into the form of very small beads, which are just flushed round the joints by means of a few puffs from a blowpipe. The subsequent operations, including the attachment of the collecting rings, must be carried out in precisely the same way as if a ball were employed for the conductor. It is, of course, highly important that the outer surfaces of the metal should be carefully cleaned up and left with a perfectly smooth and even surface, free from dents or imperfections. If you are not handy at brass-work, you have yet another alternative plan of making the prime conductor. You can turn a ball in a lathe from a block of sound, dry wood, and then insert the conducting fittings in the usual manner, and afterwards cover the entire surface with tinfoil or gold-leaf. Tinfoil, which would be the best to use, should be cut into the form of a series of longitudinal strips, similar in form to a section of an orange, which are then pasted on to the surface of the ball, and smoothed down until quite smooth by means of a piece of soft wadding and a hone paper-knife, or the handle of a tooth-brush. Glass rod and tubing of all sizes can generally be obtained from an electrician in any large town; or, if you experience any trouble in getting it, you might send to Prof. Caplatzi, stating the diameter and length required, which will be cut off and charged for at the rate of 1s. per lb.; or, if you prefer to go to the fountain-head, you can obtain it from Mr. D. Williams, experimental glass blower, Beech Street, Barbican, London, who deals in glass rod and tubing, and is a manufacturer of chemical and scientific glassware, including incandescent lamps, thermometers, etc.—C. A. P.



Prime Conductor of Winter Electrical Machine, with Side removed, showing Arrangement of Interior—A, B, Brass Tubes.

**Zither.**—W. J. (*Belfast*).—I replied to W. J. a short time ago on the above subject, giving him full information thereon; but it appears from his question, as now put, that he has not made a zither proper at all, but only one of the toy kind, better known, perhaps, as "Prince of Wales's harp," for which, of course, my instructions are useless. As, however, the instrument, even considered as a toy, is, especially if well made, capable of producing very sweet sounds, it is quite worth the trouble of stringing up properly. To do this, the following steel wire should be used: first and second strings (commencing from the bottom, or longest), No. 12; third and fourth, No. 11; fifth and sixth, No. 10; seventh and eighth, No. 9; ninth and tenth, No. 8; eleventh and twelfth, No. 7. If the first of these are rather "twangy," it will be as well to substitute covered strings (copper on steel), such as are used for the fourth and fifth of the zither proper. The tuning is a very easy matter, the scale being the ordinary "diatonic" scale; and it, of course, limits the tunes capable of being played on it to those standing within its compass, and containing no "accidentals," either sharp or flat. If these instructions are not sufficiently explicit, and W. J. will write again, giving the dimensions of his instrument, and, if possible, a rough sketch, I shall probably be able to assist him further; but he must not be so impatient at not getting a reply *at once*. He must remember that "big wheels move slowly," and "Shop" has now become a very "big wheel" indeed; but not so big but that his "spoke" will surely come round in time.—R. F.

**Acid and Gilding.**—AN IMPROVER.—*Hydrofluoric acid* is the name of the chemical compound used by glass writers, which has the property of disintegrating or eating into glass and kindred substances. This is the article which has been in use for many years for embossing, the parts to remain clear being eaten out to a lower level than the original surface of the glass, which latter is then obscured by grinding with emery and a glass slab. This should only be used with plate-glass. *White acid* is a comparatively modern invention, and is a compound which not only eats into the glass, but *obscures* the same in one action; it can, therefore, be used for sheet-glass, and is really a tremendous advance upon the "old fluoric" for many purposes connected with glass embossing. For further useful particulars, see previous answer to "Acid and Gilding" in present volume. The exact proportions used in making isinglass mordant, or size, for glass gilding, is a matter on which there is no necessary unanimity of opinion. The true theory of the process is this: that the mordant is only a temporary expedient to enable us to manipulate the gold; to gild and "double gild," and hold it in position until, by hot bath washings, we are able to dissolve it from its place and leave the gilding in perfect contact with the glass. This process, which is really the pith of the burnishing, is difficult to succeed with until practice and experience have been paid for by the inevitable failures and renewed and conquering perseverance. My advice is, therefore, to use only as much *finest* Russian isinglass as will cover a shilling; to put this into a new and thoroughly clean glazed earthenware pot (the London painters' "hand pot," or the best substitute you can get); pour over it a pint of boiling filtered water; then, as an extra precaution, when quite dissolved, strain through silk or the finest fabric you can get it through; and, finally, be sure glass, brush, and everything else are scrupulously clean. Many writers add to their size an equal quantity of spirits of wine; this is neither necessary nor advantageous. The most fruitful causes of failure and disappointment in obtaining good burnish are these: using foreign-beaten gold out of ordinary rouged books; using the size too strong; insufficient washing; improperly cleaned and greasy glass, tools, etc.; and *want of experience and practice* most of all.—F. P.

**Polishing Marble.**—J. S. F. (*Swindon*).—As your query evidently refers to a piece of real marble, you will find the surface polish will be renewed by taking a little rotten-stone (finely pulverised), and rubbing the slab with this and a small piece of fine marble or stone. Work with a circular motion, using water only if it is a light marble; but, if black, sweet oil may be substituted for the water, which fluids are, of course, used in conjunction with the polishing slab and rotten stone. Time and patience are also required in considerable proportions.—F. P.

**Colouring Figures.**—CLAUDE.—The only method I can suggest for colouring the small plaster figures after the manner you desire, is to dip them into a solution of the ordinary dyes. Cheap dry pigments, such as Venetian red, French ultramarine blue, and raw sienna (in water), would, if fine in quality, make coloured fluids which would dye the plaster; but some of them would not "bind" as firm as the chemical dyes, nor would the action be so regular as the latter solutions. Why not colour the plaster by mixing it with coloured water? Have you tried this?—F. P.

**Stain and Arches.**—E. B. C. (*Cheltenham*).—I do not know that there is anything recognised as *the* stain (green) for furniture. Get some green dyes, and select the one which gives the colour you like best. Plenty of shades are to be got. I hardly understand your inquiry about arches, but any outline can be cut with a bow-saw. Perhaps this hint may help you; but if it does not, write again, giving us a little more idea of what you mean by Moorish arches for corners of rooms.—D. D.

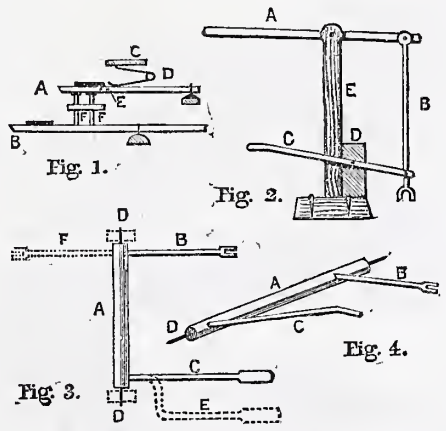
**Employment.**—J. A. N. (*Portsmouth*).—If you want to improve yourself, and get employment in a cabinet shop, why not try those in your own neighbourhood? WORK is very glad to help anyone on; but, really, it can hardly become a labour agency; and I daresay you know the saw: "Heaven helps those who help themselves." Go about among the cabinet-makers in your own and neighbouring towns, and keep your eyes open for a vacancy. If you were in a remote country village, it might be meet to write you differently; but situated where you are, you have more chance of finding a place to suit yourself than you would have by travelling to any town we might tell you of. How would you like, for instance, to be told that you might get into a shop in Liverpool or Edinburgh, and when you got there find that the foreman could not estimate your abilities at what you might consider a fair value. Whether you could bind yourself for a year's service would depend very much on your employer. If you are a smart,

handy man, where would be the use of doing so? and if you are a duffer, your employer might object. Without knowing your work, it is impossible to say what would be suitable wages. You might be cheap at 30s. a week or dear at 10s.—D. D.

**Bleaching Wood.**—J. T. H. (*Liverpool*).—I am not aware of any steaming proeess by which such woods as maple and sycamore can be bleached and made white; but you may lighten almost any wood by washing it with a solution of oxalie acid in water. From your memorandum heading, though, I imagine it is not worth while in your business to take much trouble in making the wood white. Possibly chloride of lime might do all you require. If you will write again, and let us know more particulars, we may be able to advise you more definitely what to do. Meanwhile, remember that oxalic acid is a deadly poison; so be careful with it.—D. D.

**Wheel.**—DOUBLE GLOSTER.—When making a new wheel to go with, and mateh, an old one, you will have to cut out a felloe pattern. Cutting from, or using, an old felloe will not do. First measure the height of the pattern wheel, not including the tire, then plaee a piece of pine ¼ in. thick upon the floor and describe a eircle ½ in. higher than the pattern wheel with trammel or eompasses; next measure the thiekness of the felloes, and if much worn by repeated re-tireing, make the new felloes ¼ in. thicker at least. We therefore reset our trammel 2, 2½ or 3 in. as required, and draw another circle within the outer one. If the wheel has 10, 12, or 14 spokes in it, we divide this eircle into 5, 6, or 7 equal parts, eaeh part or arc representing a felloe. Be sure that a felloe is deseribed and marked out upon the board. We now saw this pattern out and mark upon it the height of the wheel it represents. We then lay it aside, and get the iron hub or nave and plaee it in the pit frame, illustrated and described in No. 15, Vol. I., of WORK; with the nave being east or malleable iron it will be ready mortised. We shall, however, require a face-stick or spoke-boy; this is a staff, and is serewed to the front of the nave so that it works stiffly about. At the top end, or nearly so, a pieee of whalebone, or cane, is inserted through a hole and plugged tightly to keep it from shifting when dishing the spoke. First get a pieee of wood and drive it into the bush at the front of the nave, then serew the faee-stick or spoke-boy at the lower end to the eentre of this plug. To set the whalebone, or cane, right for dish, we plaee a straight-edge aeross the faee of the hub or nave, then measure the distance between the front of the spoke near the felloe and the straight-edge. Whatever this measurement may be, we let the whalebone, or eane, protrude from the face-stiek, bore a hole with a shell-bit the same distanee up the stick as the top end of the spoke near the felloes is from the nave in the old wheel, then set the whalebone right and plug tightly, to keep from shifting when onee set. When the spokes are dressed off the same as the old ones—exeepting the tangs, or tenons, whieh we do not toueh at present—we eommenee to drive them in; get a spoke and pare it down until it fits the mortise easily, as it will tighten the further it is driven. Hold the spoke-boy at the front, and see that the face of the spoke only just touches the end of the whalebone, or eane, then drive the spoke home; these spokes must be driven in alternately, and not one after the other, or the nave will split. When driving a spoke in always have it perpendicular—the faee-stiek can be worked round to eaeh spoke without unserewing it. When all the spokes are driven in we lay the wheel down, letting the nave rest upon a block faee upwards; then measure from the top of the nave to the top of the felloe on the pattern wheel; then get a staff one end wedge-shaped, so that it will touch the nave between the spokes. At this measurement, from the nave to the top of the wheel, we mark upon the staff, and insert a sharp bradawl and seratch the spokes all round, afterwards sawing the superfluous away. Next measure the thickness of tbe felloe; if 2 in., insert the bradawl 2 in. lower down, and mark each side and back of the spokes; we are now marking them off for tenons. If the wheel is a light one you are making, the tenons will be round; if a heavy eart wheel, tbey will be square. If round, we saw with the tenon-saw round the spoke—more at the baek and front than the sides; whatever the strength of the tenon is to be, we get an auger and bore a mortise hole through a pieee of oak 1 in. thiek (this same auger must bore the felloes). When all the spokes are sawn round, plaee the wheel in the pit frame, then place the pieee of oak on the top of the tenon and mark with pencil; pare the tenon down until the mortise pattern fits it; serve all the other tenons the same. We lay the wheel upon the block again, faee upwards, and get our felloes ready; if you buy them ready sawn you will say what size of a wheel you intend making; and when you get them, plane one side up straight and true, then place the felloe pattern upon it and mark with the peneil; then saw and chop off the superfluous, using the square often. When all are marked in this way we place them upon the wheel, letting the felloes rest upon the tenons; the joints of two felloes always eome in the centre between two spokes; if the felloes do not fit, we take a little joint out until the rim is eomplete. Next run the pencil at eaeh side of tbe tenon, thus marking the felloe; then number the spokes and felloes to correspond when putting together; also draw a straight line across the joint; get a felloe and mark with the square from this line, then set your gauge for the centre and also mark and bore for the mortises. Then, after the mortises have been bored, we have an ineh or so at the end of the joint for a dowel hole; these dowels will be 2 or 3 in. long, oak pegs or round iron ones. Now dress the felloes off the same as the old pattern, then insert a dowel at each end of a felloe and knock them on. Next insert the chisel in the tenons—not horizontal, but perpendicular—and wedge the tenons up with good oak wedges. We now give the wheel a coat of paint, and when dry send it to be hooped; when the tire has been put on we dress the rim of the wbeel all round, baek and front, near the hoop, and also the joints; then paint it, and your wbeel is made. In Vol. II., in "Shop" (p. 225), will be found sketches illustrating making and putting a wheel together.—W. P.

**Organ Matters.**—T. W. (*Gamesley*).—You ask how you can lighten the touch on the upper row of keys whieh you bave fitted to your organ. As shown in the sketeh which aeeompanies your query, it would appear that the keys have no independent connection with a second manual, but merely press down the keys of a lower manual by means of a plunger plaeed under the fore part of the keys. If this is so, I tbink the touch could easily be ligbtened by weighting the fore part of the upper row of keys with lead weighting, so that they almost press down the lower row, only requiring a slight touch to cause them to act. The weighting could be inserted in the keys in the same way as it is done for the purpose of balancing them. Or you could secure tbe same end by placing a spring over the fore part of each key, one end of the spring being on the key, and the other end fixed in a spring rail about 2 in. above. The sketches will explain how this is done. Either of these plans could be tested by trying the weighting or spring on a single key. You also ask how you can adapt a foot-blower to the organ, so that you ean be independent of a hand-blower, who is not always available when you require his serviees. Have you tried a pedal, working on a eentre pin on the same standard as the arm of the hand-blower, the further end being loosely pinned on to the lug of that blower, as shown in Fig. 2? If neeessary, a bloek could be screwed on to the standard, so that the pedal blower could be centred nearer to the lug, and thus obtain greater leverage and lighten the foot pressure required. The pedal could be bent round so as to bring it within easy reaeh of tbe foot. If this plan is not praetieable, then it will be necessary to adopt the roller system, whieh is shown in Figs. 3 and 4. A stout roller, eentred on a strong pin at eaeh end, is plaecd eross-wise under or near the end of the bellows, and elose to the floor. At the front end of the roller is an arm, carrying a pedal plate; and if this arm is not to be entirely in front of the easing, it must be bent, as shown in the dotted lines of Fig. 3. This arm is made to slope upwards, and another arm is fixed to the further end of tbe roller, sloping very slightly downwards, and having a lug, or a little wheel, at its free end, so that it will either be pinned to a eonneetion with the under-side of the feeder, or will press against the same part of the feeder. The roller and arms can be made of wood or iron; the latter would, of course, be strongest, and take up least space. The arms can be both on tbe same side of the roller, or on opposite sides, according to the position in which it has to be fixed under the instrument; and tbis will, of course, depend on the amount of room available, so that it may not interfere with any of the action. It can be made to work with either right or left foot, as required, aeeording to the positions of the arms on the roller; and, of course, the longer the pedal arm the more leverage.—M. W.



**Organ Matters. Fig. 1.—A, Upper Keys; B, Lower Keys; C, Spring Nail; D, Spring to press down Keys; E, Lead Weighting; F, Plungers. Fig. 2.—A, Hand-Blowing Handle; B, Lug; C, Suggested Foot-Blower; D, Block for centring Foot-Blower; E, Standard. Figs. 3 and 4.—A, Roller; B, Back Arm with Lug; C, Front Arm with Pedal Plate; D, Centre Pins and Blocks; E, Suggested Bent Arm for Pedal; F, Suggested Arm on reverse side of Roller.**

**Musical Box Combs.**—J. B. (*Kennington*).—You did a most foolish thing by unscrewing the flyers or fan part of musical box. Had you read the chapter on musical boxes, you would have seen that the driving part containing mainspring must be at rest—no pressure on the barrel with pins in it. I stated it clearly, so that no one could make a mistake. The same aceident has resulted in the destruetion of hundreds of good boxes. I see it is some time ago that this oeeurred, so it is evident you have not seen the pages of WORK. So many of the teeth are gone, that repairing is out of the question; and if you will look at the barrel with a magnifying-glass, you will see one tune destroyed—that is, the pins that acted on the teeth of comb will be bent, and lots broken. That you ean remedy (see chapter on Musical Boxes), but you will require a new comb; and if box has tbe maker's name upon the card—which it will have—also the *number* of box, you ean get a new comb to exaetly fit and with the least trouble; it will be Geneva, Switzerland, as no one in England sells them. The cost will be about 25s. to 30s.; earriage extra.—J. S.

**Cloth Paint.**—D. M. (*Glasgow*).—If you had stated the nature of your fabric, and your ehief reason for desiring to paint it, I might more definitely have replied. I do not, however, think you can better a mixture of "boiled oil"—viz., boiled *linseed* oil and patent paste driers, such as is used for sailors' oilskins, etc. A little pigment might be added to colour the mixture, if desired, or even a little white lead; but the paint should only well saturate the eloth and not lie on the surface, or else you will get a film that will crack. About 1 lb. driers to 1 quart boiled oil.—F. P.

**Pine Polishing.**—C. A. (*Birmingham*).—To stain and polish your pine ehest of drawers in imitation mahogany, you cannot do better than proceed as follows: (1) Stain tbe job with tbe brown or walnut stain of vandyke brown, amuonia, and water. Mind that this stain is only to be a weak one, not by any means so dark as if the wood were required to be finished walnut colour. (2) Fill in with a mixture of turpentine and whiting, eoloured with a little Venetian red. Rub this well in, and clean off all the surplus before (3) bodying in with ordinary Freneh polish, reddened with Bismarck brown. Be eareful not to use too much of the Bismarck brown, as it is a very powerful colour. About a pinch of it to a pint of polish will be suffieient. (4) Finish off with a mixture of equal quantities of Freneh polish and glaze, applied with a tolerably wet rubber. This method of finishing will probably suit you better than spiriting off, as it is both easier and quicker. You may as well buy the Freneh polish and glaze ready-made. In justice to tbe French polisher, whom you faney wanted to over-charge you, I may state that the figure you name is by no means excessive. Of course, if it is more than you wished to pay, you need not have the work done by him; but you must remember that polishers have to live by their trade, and you could not expect him to do your ehest of drawers without a reasonable remuneration. When you have done the job, just reckon how mueh materials have eost you, and the number of hours you have spent on it, and then, by assessing your time at a very moderate value, you will see there is not much ehange out of 7s. 6d. To this add the reflection that if the work had been done for you it would, probably, have been far superior to what yours—as you are a novice—ean possibly be. This leads me to say that as you have never done any polishing, if you make your first attempt on your chest of drawers, you need not be surprised if you spoil the job. Try first on a pieee of waste wood, just to get your hand in, and to get some idea of the tints.—D. D.

**French Polishing.**—J. E. (*Blackhill*).—If you have done "fairly well" with your eseritoire, without having had any previous experience in polishing, or more knowledge than you have been able to pick up from hints in "Shop," I am inclined to say that you have done not fairly only, but very well. Without praetice, you could not expect to get the polish "up to the mark" like an experienced polisher would; so I tbink you have every eause to be satisfied. Of course you will do better as you proeeed, and from your letter you seem to have somewhat misunderstood the various operations. You will do better by using methylated spirits only in finishing. Of course, the bodying in, or what you call the last coating, must be dry before you spirit off. You will have observed that the body polish dries very quiekly, and even if you tried, I do not think you could spirit off while it is wet. The spiriting is merely done to remove the streakiness left by the polish rubber; so that, you see, there is no necessity for doing it till tbe last thing. If you body up well, several coats of polish are not necessary, though there may be no actual barm in them. A good deal depends on tbe nature of the work in hand.—D. D.

**Polishing.**—W. R. (*Newcastle*).—The fine little eracks on the polish of your piano are caused by what is teehnically known as sweating, *i.e.*, either the grease whieh may have been in the eomposition of the filling, or oil, used in the polishing process, has sweated through the thin coating of shellac. The cracks, or sweating, beeome visible from the dust which settles on the oil. Therefore, the disfigurement caused can almost entirely be averted by earefully wiping new furniture now and again with a soft damp cloth. When the oil has done exuding, which may not be for some months, the work may be re-polished with advantage. Sweating is not entirely preventible. Possibly you might be able to remove the dirt with warm water and a little

soap; but it will be better for you to nse a reviver, composed of vinegar, raw linseed oil, and methylated spirit, in about the following proportions, which, however, need not be closely adhered to: ½ pint of vinegar, 1 noggin of spirit, and a tablespoonful of oil. Use this on a piece of soft rag, and a small amount of rubbing will remove all the sweating. To toucb up the parts where the black has been worn off, use some black polish, made by mixing gas black with ordinary French polish. Go over the bare parts with this by means of a rubber till they are snfficiently ebonised, finishing off in the usual way. Yon must remember that you will probably have to go over the whole job with polish to prevent the newer portions looking different from the old. If the work is properly done, the case of the piano ought to look as good as new. Of course, if you like to do so, you may re-stain; but as this involves removing the whole of the present or existing polish, you will probably prefer the simpler method which has been indicated. If your piano is a valuable one, yon had better employ a skilled French polisher to do what is necessary.—D. D.

**Brass Water Aspirator.**—WATER ASPIRATOR asks O. B. to give a few measurements of the brass water aspirator described in WORK, Oct. 24th. In reply to this, I think it will be sufficient to say that Messrs. M. and S.'s instrument, in glass, is about 8 in. long. The illustration given, though not drawn to scale, supplies, with this one measurement, sufficient data, I think, to construct such an apparatus.—O. B.

**Capacity of a Tank.**—W. C. (*Deptford*).—To find the capacity of a square or oblong tank, multiply the length in feet by the breadth in feet by the depth in feet. This gives the capacity in cubic feet, and if multiplied by 6·2321, the capacity in gallons. Example:—A tank 10 ft. long by 4 ft. wide by 6 ft. deep will hold (10 × 4 × 6 =) 240 cubic feet of water, or (240 × 6·2321 =) 1495·704 gallons. To find the capacity of a round tank, multiply the depth in feet by the square of the radius in feet by 3·1416. This gives the capacity in cubic feet, and, if multiplied by 6·2321, the capacity in gallons. Example:—A tank is 5 ft. high, and has a diameter of 8 ft.; the radius, which is half the diameter, will therefore be 4 ft., and this, squared, is (4 × 4 =) 16 ft.; therefore, capacity equals (5 × 16 × 3·1416 =) 251·328 cubic feet, or (251·328 × 6·2321 =) 1566·3 gallons. One cubic foot of water equals 6·2321 gallons.—F. B. C.

**Size of Cylinder of a 1-Horse Engine.**—J. H. (*Lower Broughton*).—No one can tell without knowing also the rate of revolution and the average pressure during the stroke. Also, it is not the length of the cylinder inside, but the stroke of the piston which you require to know. You will find all this fully explained in No. 106 of WORK. If, however, you mean, not an actual horse power, but a nominal horse power (a conventional term by which engines are sold, and has very little to do with the power they can exert), then you can obtain the information from the price-lists of engine-makers, striking an average; for they will not exactly agree. Looking at the price list of Hindley, of Bourton, Dorset, I find he allows for a 1-horse engine a cylinder of 3 in. diameter and 4½ in. stroke. To show you how little that has to do with the actual horse power, I may say that, supposing this engine would exert 1-horse power when supplied with steam at 50 lbs. pressure, then it would exert 2-horse power if worked with 100 lbs. steam. If, again, it gave 1-horse power with 50 lbs. steam at 100 revolutions per minute, then it would give 2 horse power at 200 revolutions. You see that, by doubling the pressure and the speed, you could quadruple the power: the same 1-horse engine might give 4-horse power; so that the size of the cylinder alone is misleading.—F. A. M.

**Camera.**—BELLOWS ON THREE LEGS.—Instructions for making this and the tripod stand appeared in the following numbers of WORK: 13, 23, 29, 70.

**Mail Cart.**—A NEW READER.—You will find that instructions for making this appeared in No. 30 of WORK.

**Safety Bicycles.**—WEEDLESS.—Consult the following numbers of WORK: 107, 111, 115, 119, 124, 127, 132, 137.

**Training.**—A. H. (*Hyde*).—WORK is not the channel for the questions you ask. Consult the Editor of *Cassell's Saturday Journal*.

**Cart-Wheel Making.**—WOOD-WORKER.—These papers are in preparation.

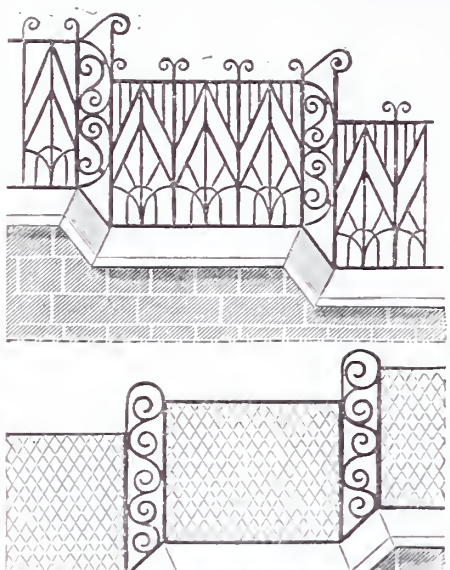
**Lathes.**—E. J. T. B. (*Barnet*).—Refer to the following numbers of WORK: 2, 3, 4, 6, 8, 10, 14, 17, 40, 45.

**Model Locomotive.**—A. E. (*Cardiff*).—You and all correspondents should repeat your questions when writing about replies which have not appeared.

**Overmantel.**—R. H. H. (*Shutter Oak*).—The demands on space in WORK are far too great to admit of the appearance of another overmantel of any kind at present. See back numbers.

**Weather Glass.**—PETERBORO'.—I may say that the glass (½ in.) mentioned in the article (see No. 135, page 483) should be procurable at any operative chemist's in almost any town. But if you cannot get it thus, you can certainly get any quantity from Messrs. Reynolds & Branson, Commercial Street, Leeds, or from any other dealer in scientific apparatus. But I do not think that any of these dealers will supply less than 1 lb., for which quantity the price is 1s., plus 3d. postage. I take this opportunity of suggesting a further improvement in the construction of the glass. I find that the greatest difficulty is in making the joint tight between the tube and the bottle. I have just constructed another glass, and have used one of the new screw-stoppered ale bottles. These have a capacity of half a pint (nominal), and for 4d. I get a caoutchouc bung, ¾ in. at the smaller end, with one hole through. Now, by wetting this, it may be firmly and tightly screwed into the neck of the bottle; and, by wetting the tube before insertion, a perfectly air-tight and flexible joint may be made. This I find to be a very decided improvement over the method I described in the article.—J. G. L.

**Wall Wire-Work.**—BETA.—I will not now give you full satisfaction, for the very good reason that to here publish sufficient explanatory notes (as you ask for) concerning the wire fencing with which you wish to adorn your wall would fill more space in "Shop" than I could conscientiously cover. Perhaps you know that my special branch in connection with WORK consists of furniture designing. But a series of articles upon Wire-Working have appeared, through the instrumentality of a practical friend, at the Editor's request. I must, therefore, ask you to be good enough to refer to them, if you think of doing anything in this line yourself. It will be some time, however, before they are complete; for, although some correspondents are under the impression that subjects they desire ought to be furnished at the instant they are asked



Wire Fencing Designs.

for, some period must necessarily elapse while all the articles are being written and drawn, then printed, then engraved, and a place found for them. To not thoroughly disappoint you, I have given two designs suitable for fencing for your wall, which, you say, has two ramps. I shall henceforth describe the putting together of the diamond wires as shown. I should advise you to have the fencing in three separate parts, with thick scroll wires soldered together, or iron scrolls between them. I should certainly not let the top line of fencing follow the line of the wall, as then you would fail to obtain any character in it. While you are waiting, remember that "patience is a virtue."—J. S.

**Provisional Protection (Patents).**—F. G. W. (*Hackney*) is, perhaps, confounding *Registration* with Provisional Protection. The stamped form for the latter costs £1. Of course, no patent agent can work for the mere price of the stamp; his fee must be paid in addition. If F. G. W. wants his work done gratis, he must do it himself; and how to do it he may learn from the article, Vol. I., p. 515.—C. C. C.

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—G. L. (*Westminster*); MARINE GLASS; W. M. (*Dundee*); R. G. (*Settle*); S. W. C. (*Leicester*); H. W. (*Norwich*); C. G. M. (*Penistone*); A. S. (*Farringdon Road*); G. T. (*Hollinwood*); R. R. F. (*Frome*); GARTAR; A. J. (*Edinburgh*); G. G. (*Llandudno*); E. MCN. (*Gateshead*); RALPHO; REX; G. F. R. (*Bournemouth*); A GUNMAN; W. L. F. (*Dublin*); L. W. (*Islington*); G. J. W. (*Ballymena*); C. J. (*Leeds*); M. (*Bishop Auckland*); R. B. (*Egremont*); MECHANIC; CHOPSTICK; J. P. (*Liverpool*); W. S. W. (*Leeds*); "WORK" READER; J. B. T. (*Manchester*); EDIPRA; W. MCK. (*Elgin*); A. W. (*Parsonstown*); YOUNG ENGINEER; J. T. S. (*Sheffield*); T. G. & SON (*Sheffield*); SPARK; A. D. (*Monkwearmouth*) LEEDS ENGINEERS' ASSOCIATION; E. H. S. (*Corfe*); W. H. (*Portobello*); A. M. B. (*Dublin*); J. S. (*Amsterdam*); J. A. (*Halifax*); F. H. (*Battersea*); J. R. (*Glasgow*.

A THRILLING CHRISTMAS NOVEL.

CLARK RUSSELL'S NEW NOVEL, entitled "Mrs. Dines' Jewels," a Mid-Atlantic Romance, appears in "YULE TIDE," Cassell's Annual for 1891, price 1s.

*A few Opinions of the Press.*

"A most enthralling story."
"Racy and readable, amusing and exciting."
"Quite in the author's best style."
"Original and very striking."
"Powerful and startling."
"Well illustrated and highly interesting."
"Of absorbing interest."
"The climax is of a most unexpected kind."

THE HISTORICAL PICTURE of the YEAR is "The Lady with the Lamp" (Miss Nightingale at Scutari, 1854), which is given away with "YULE TIDE," Cassell's Annual for 1891, price 1s.

*Opinions of the Press.*

"A unique presentation plate."
"Alone worth the price of the annual.
"A magnificent picture."
"Surpasses all its predecessors."
"A most striking and impressive picture."

CASSELL & COMPANY, LIMITED; *and all Booksellers.*

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

### A SMALL POULTRY FARM.

BY G. P.

INTRODUCTION—DIMENSIONS OF VARIOUS BUILDINGS—MATERIALS FOR VARIOUS PARTS: WILLESDEN PAPER, MATCH-BOARDING—CONSTRUCTION OF FRAMEWORK: SETTING OF CORNER POSTS, FIXING CROSS-RAILS, SETTING AND FIXING RAFTERS OF POULTRY HOUSE, SETTING AND FIXING RAFTERS OF COOPS.

*Introduction.*—Much is written and talked in the present day on the subject of poultry farming. One enthusiastic party declares that this much-neglected branch of farming is the thing which is wanted to do away with hard times. We see columns of figures to prove how much money goes out of Great Britain for eggs and poultry; and the writers of these columns generally have another set of figures to prove how easily the British farmer might divert the stream, and land all these hundreds of pounds in his own pocket. On the other side, we hear of the utter failure of attempted poultry farms; the difficulty of keeping a large number of fowls in health on the same ground; the obstinate way in which hens refuse to lay at the time eggs are fetching a good price; the prodigal way in which they present us with eggs when they are scarcely worth selling; and so on, and so on. My own opinion, after a good many years' experience as a poultry keeper, is that there is a good

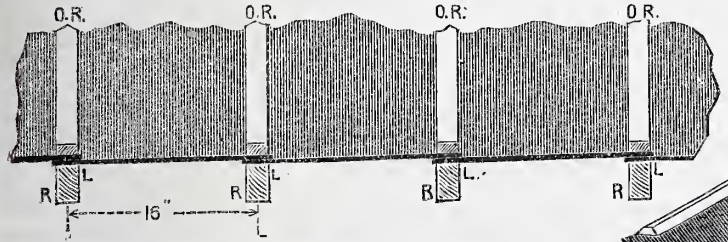

Fig. 5.—Section of Fig. 4 along line A B—R, Rafters; W R, Willesden Roofing; L, Three-inch Overlap at Joints; O R, Outside Rafter.

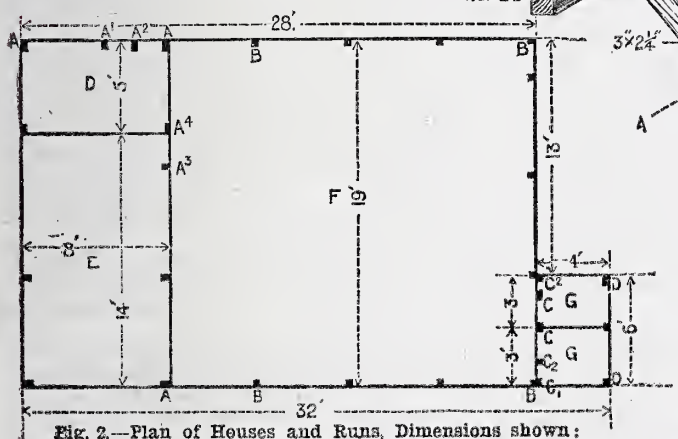

Fig. 2.—Plan of Houses and Runs, Dimensions shown: D, Large House; E, Run; F, Grass Plot; G, Coops.

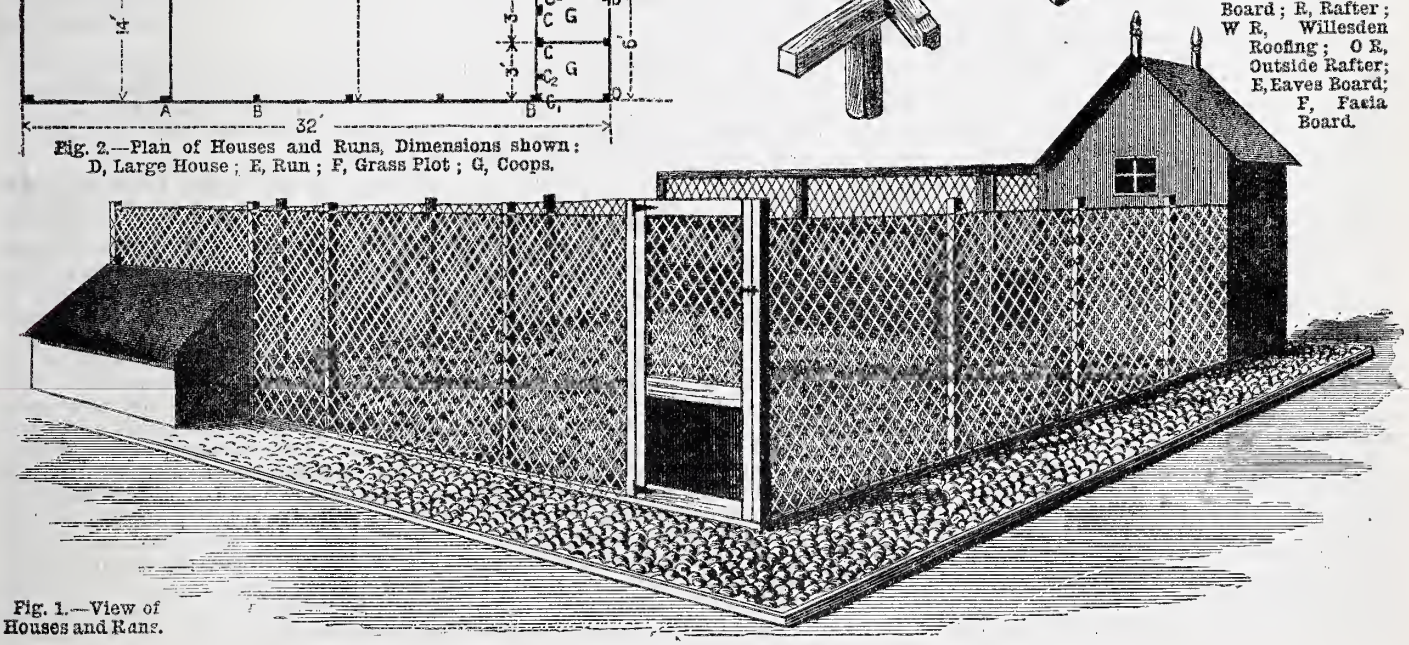

Fig. 1.—View of Houses and Runs.

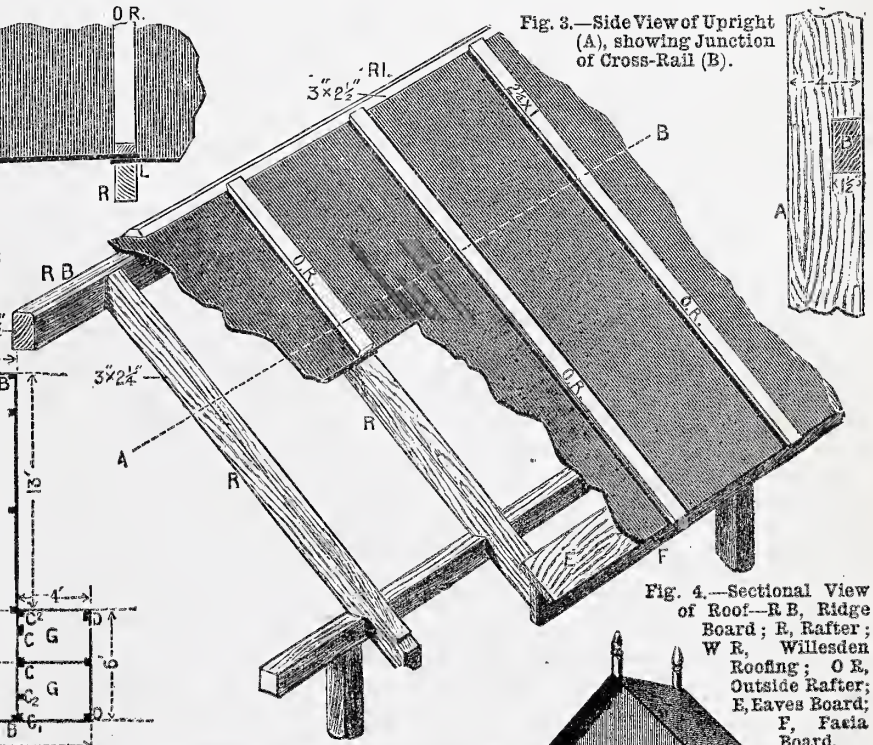

Fig. 4.—Sectional View of Roof—R B, Ridge Board; R, Rafter; W R, Willesden Roofing; O R, Outside Rafter; E, Eaves Board; F, Facia Board.

Fig. 3.—Side View of Upright (A), showing Junction of Cross-Rail (B).

deal to be said on both sides of the question. I confidently believe that hens properly housed, well attended to, getting good grain and soft food, green meat—such as grass or vegetables—and not overfed, pay well, the annual profit being fully 4s. per hen. But it is recognised by all experienced in poultry keeping that the first essential to success is thoroughly good housing; and it is with the object of showing my readers how to construct a thoroughly good, water-proof, draught-proof, and warm abode for their fowls that I write this paper. The illustration (Fig. 1) is a view of a small poultry yard. The original has been in use for a number of years, and has been found to be very satisfactory. It is compact, very convenient, and suitable for an amateur poultry keeper, providing him with room for one variety, and also with accommodation for hatching eggs and rearing chickens.

*Dimensions of Various Buildings.*—The poultry farm consists of one large house, 8 ft. 4 in. long by 5 ft. broad, by 6 ft. high at the eaves and 8 ft. 9 in. high at the ridge; with a run 14 ft. long by 18 ft. 4 in. wide by 6 ft. high, attached. In front of this house and run is a grass plot 20 ft. long by 19 ft. broad; and at the side of this grass plot, remote from the house and run, are two or three chicken-coops, in which eggs are hatched and chickens reared.

*Materials for Various Parts.* — Before commencing to build, we will, of course, have to provide ourselves with materials, a complete list of which will be given at the end. In that list it will be noticed that a material called Willesden Paper is mentioned, and as some—perhaps most—of my readers may not be familiar with the name, I had better describe what the material is, and what it is used for.

*Willesden Paper.*—For a long time it has been known that paper, canvas, etc., when placed in a solution of cuprammonium hydroxide, become gelatinised and diffused through the liquid. This could not be made of any practical use until the Willesden Paper and Canvas Co. conceived the idea of passing the substances through at such a rate that the exterior of the fibres only was gelatinised; then, by subsequent drying, an elastic varnish was formed, which readily took up copper in the form of cuprocellulose, thus preventing the material from being affected by water or damp. The above-named Company have been now working the process, with such modifications as have been suggested by experience, with great success for a considerable time, and their goods are becoming more popular year by year; but as yet, the substance has not been very much used by amateurs—principally, I suppose, from their ignorance of there being such a material in the market. This is a great pity, and one which should be remedied. The two kinds of paper required for this building are the four-ply and the one-ply. The former is extensively used as a building material, and is required by us for the roofs of our buildings. For this it is especially suitable, for, besides being cheap and easily fixed, it is entirely weather-proof, being affected by neither damp, nor frost, nor excessive heat. It is much warmer than galvanised iron, and, area for area, is only one-ninth the weight. The one-ply papers are for underlining slates, partitions, damp walls, stencil-paper, etc. We are to make use of them for lining our houses, for, being rot-proof, water-proof, insect-proof, inodorous, and warm, they are just what is required for lining a poultry house. These papers may be had in rolls of any length, the four-ply 19 in., 27 in., and 54 in. wide, at 9d., 1s. 2d., and 2s. 3d. per yard run respectively; and the one-ply brown, No. 1.80, 56 in. wide, at 6d. per yard run, from the Willesden Paper and Canvas Works, Willesden Junction, London, N.W. It will thus be seen that the name "Willesden," as applied to the paper, is derived from the name of the town at which it is manufactured, and not from the process it has been subjected to.

*Match-boarding.*—I have mentioned this in the list to be used for covering the framework of the houses, not because it is preferable to Willesden, but because it may be put up at *slightly* less expense, and because it will suit the secondary purpose for which it is here required.

*Construction of Framework.*—Having now provided ourselves with the materials named in the list, we may set about the construction of our poultry house.

*Setting Corner Posts.*—We first take the eleven 4 in. by 2 in. posts, char the lower ends, and coat them well with coal-tar; then place them firmly 2 ft. in the ground, in the positions marked A, Fig. 2. As it is better to do all work of the same kind at one time, we had better now put in the corner posts for the chicken-coops, and also those for the fence round the grass plot. The poles for the plot are 1½ in. square, and are driven 2 ft. into the ground, in the positions indicated at B, Fig. 2. The height of the fence depends on the breed chosen. Cochins or Brahmas are easily retained within bounds by netting a yard high; for moderate-sized fowls, 5 ft. high will do; whilst to confine game, Hamburghs, or bantams, a fence of 8 ft. or 9 ft. in height will be found necessary. I have made provision for a fence 5 ft. high, this being the usual. The corner posts for the coops will have to be 2 in. by 2½ in., those marked D (Fig. 2) being 4 ft. long and placed 1½ ft. into the ground, while those marked C are 6 ft. long, and are placed 2 ft. into the ground. The lower ends of all these posts should be previously charred and coated with tar.

*Fixing Cross-rails.* — Horizontal rails, 3 in. by 1½ in., are now to be fixed between the uprights of the large house about 18 in. from the ground, and also across the top of the corner posts; while similar cross-pieces are fixed across the tops of, and half-way up, the posts round the *run*. When putting up these lower horizontal rails, spaces must be left for the doors into the house and into the run (see A, $A_2$, and $A_3$, $A_4$, Fig. 2). With regard to the coops, cross-pieces must be fixed along the tops of the corner posts of these, and similar cross-pieces 1 ft. from the ground. These rails are 2 in. by 2½ in.—*i.e.*, the same width and thickness as the uprights. "Oh! it is all very well telling us that it must be done; but how is it to be done?" I fancy I hear some amateur say. Well, it is really so simple I had almost passed it over. But let me answer: "Principally with nails." The rails are made to fit exactly between the uprights, and are nailed there with two or three 2½ in. nails, put in on the slope. Those pieces round the large house and run had, however, better be let into the uprights (see Fig. 3).

*Setting and Fixing of Rafters of Poultry House.*—Good and cheap rafters for the roof of the house may be obtained by sawing two flat cuts in 7 in. by 3 in. battens, which will give three pieces, each 3 in. by 2½ in. Those for the ends of the house are 4 ft. 1½ in. long: they are halved into each other at their top ends, and the bottom ends are let into the top horizontal rail (see Fig. 4). The ridge board (Fig. 4) is now nailed on, and the remaining rafters, each 4 ft. long, are fixed as in Fig. 4. The correct spacing of rafters must be as shown in detail at section A B, Fig. 5—viz., 16 in. from centre to centre of rafter.

*Setting and Fixing Rafters of Coops.*—Similar construction is required for the roof of the coops, the only difference being that it is a *lean-to* roof—viz., one consisting of a single sloping piece—instead of a *span* roof, which consists of two sloping pieces forming an angle with each other, and which is really two lean-to roofs joined together. The rafters for this roof are 4 ft. 8 in. long.

Space forbids, and I must needs leave over the rest of my remarks for a future number of Work, at no very distant date.

## HOW TO SECURE COPYRIGHT IN DESIGNS.

BY CHARLES KELSEY.

MAKING THE APPLICATION — WHERE TO OBTAIN APPLICATION FORMS: THEIR PRICE—FILLING UP THE APPLICATION FORM — STATEMENT OF NATURE OF DESIGN—THE REPRESENTATIONS — PROVISIONAL REGISTRATION — ISSUE OF CERTIFICATE—LENGTH OF COPYRIGHT—CONFLICTING DESIGNS—CONSENTS—INSPECTION OF CONFLICTING DESIGNS—ACTIONS FOR INFRINGEMENT.

HAVING in my previous paper dealt with the definition of a design and proprietor, and explained the conditions which must exist precedent to registration, and also explained the manner in which designs are subdivided for the purposes of registration, I will proceed to treat of the other matters relative to the subject.

*Making the Application.*—This consists in lodging at the Office an application form properly filled up, together with three representations of the design. I will deal in the first place with the application form.

*Where to obtain Application Forms and their Price.*—These are sold not at the Patent Office, but at the Inland Revenue Office, Royal Courts of Justice, London (Room No. 6). Also, speaking generally, at all the more important post-offices in the kingdom; and if not kept in stock, may be ordered at any money-order office in the United Kingdom.

There are two principal forms: Forms E, for the classes from 1 to 12, cost 10s. each; Forms E, for the classes 13 and 14, cost 1s. each, stamped.

These fees, trifling in themselves, are all the expense that the application involves—that is, if the designer or inventor makes his application himself, without employing a patent agent.

When he intends to apply the same design, with, perhaps, various small modifications, to a set of articles such as are ordinarily on sale together—such as, for example, a dinner or dessert set, a tea or coffee service, a set of fire brasses, a suite of furniture or a suit of clothes—Form O, costing £1, should be used.

*Filling up the Application Form.*—First insert, in its proper place, the number of the class in which it is desired to register. This will be obtained from the list previously given. Or, in case of doubt, ask the Comptroller to decide for you, telling him of what materials the design is composed, and how it will be executed. Then insert the full name and address, and the trade, profession, or calling of the applicant. Then where the certificate is to be forwarded to; if the inventor is applying himself, he merely says to himself at the above address; but if a patent agent is

acting, he naturally inserts his own address, so as to have the certificate through his hands. And then, at the foot of the form, is a space for the insertion of the applicant's or his agent's signature, and for the date of the application.

If an agent is employed, the applicant signs a Form of Authorisation for the agent to act in his stead, which is filed with the application form.

So far, all is very simple, and the only point where any difficulty will be experienced is in filling up the remaining space. This is for the

*Statement of Nature of Design.*—By the Act and rules, the filling up of this part is made imperative, the object being to make the applicant define clearly what the registration is for. The applicant must therefore state whether it is the shape or configuration, the pattern or the ornament, or any two or more of these which he desires to protect.

He selects the most fitting term or terms, and after the foregoing remarks little difficulty will be experienced in this. If all is new—shape or configuration, pattern and ornament—and he desires to claim for all, he can do so. If only the pattern or ornament is new, he claims for this alone, and the same in reference to the shape.

If only a portion of the article is novel, he should claim only for that portion, distinguishing it by letters or figures corresponding to similar letters or figures upon the representations. A good plan is to tint the part claimed as new in some distinctive colour.

It is better also to indicate what the article is, in the claim—such as "Design for a Bicycle Frame. Applicable for the shape or configuration;" unless the drawing is self-intelligible, or words appear upon the drawing to that effect.

In cases where a new shape is designed which will be decorated in a variety of ways, it is best to claim for the shape alone, leaving the after-applied decorations to be specially applied for if considered sufficiently important. In cases where the design sought to be registered is a pattern or ornament which can be applied without modification to various articles—as in the transfer prints used for the decoration of china, or the engraved ornament applied to silver or electro-plated goods—the registration may be claimed in a general way for application to all the goods included in the particular class. But when the application is for the registration of a shape, this is hardly possible, as the application to varied articles to be used for distinct purposes necessitates variations in the shape, and such variations require to be separately registered, unless it is such a case as can be included under the Set form previously alluded to.

But the courts have held that mere variations in size, where the relative proportions of the various parts are not altered, will all be protected by the one application. This completes the filling up of the application form, and it will be seen that it is a very simple matter, which may be accomplished by almost any person without assistance, and thus the services of a patent agent may be dispensed with, and the payment of his fee avoided.

*The Representations.*—Accompanying each application form must be sent three exactly similar representations of the design. Considerable latitude is allowed on this point, which favours the applicant greatly. He can send drawings or tracings of his designs, impressions pulled from copper-plates, prints from wood blocks, such as are used for advertising the articles, photographs of the designs, rubbings from book-covers or flat metal goods; or in the cases, like textiles, paperhangings, and paper-like articles, actual pieces of the finished articles.

The drawings should be executed upon paper of foolscap size, 13 in. × 8 in., where possible, and two views may be shown, or in cases where more are required to show the design properly, this number can be amplified; they should be executed in ink, or, if in pencil, should be fixed by a wash of gum-water or water-colour, and the tracings must be upon tracing cloth—not upon thin tracing paper—so as to secure a permanent record of the design.

The drawings or tracings need not be artistically executed. The only requisite is that they should show the design properly and clearly; but very rough sketches should not be sent, for if the design is not shown properly, the loss will be the applicant's own.

Photographs should be mounted upon similar foolscap paper—not upon thick cardboard—and the applicant should, for his own safety, obtain permanent prints. If specimens are lodged, they should be of the same size—13 in. × 8 in.—as nearly as possible; but if a larger size is necessary to show the design properly, they will be accepted up to 21 in. × 12 in. If the pattern is not complete in this larger size, photographs of the pattern should be sent.

An applicant may easily decide for himself whether specimens of a particular design will be accepted in lieu of drawings or other representations, by asking himself whether the article is such a one as could be pasted into a book without cutting or bursting through the adjacent pages. Speaking generally, all that conform to these conditions will be accepted.

When sets of articles are required to be registered, the representations should show the variations which will occur on the different articles.

*Provisional Registration.*—In cases where the applicant wishes to secure an early date of registration before his drawings are executed, or other representations prepared, he can forward one sketch of his design with the application form, and this will be accepted by the Office, and the certificate will be dated from the day of the receipt of the application form; but no certificate will be issued until the proper drawings are sent.

The applicant must not deliver any articles on sale before the certificate is issued, or his registration will be invalidated, the Comptroller in such cases having the power to strike the design off the register.

The applicant may, however, after the date of the receipt by the Office of the sketch of the design, solicit orders to ascertain if it is worth while proceeding with his application. The sketch should be such as to show his design properly; and when sending the complete representations, he should not depart in any material particular from the one first lodged.

*Issue of the Certificate.*—About eight or ten days after the receipt of the application, if all is correct, the certificate of registration will be issued, and forwarded by post to the address given by the applicant.

If not in proper order, the applicant will have it returned to him to make the alterations desired by the Office, which will be indicated in the letter accompanying the returned documents; and on his amending as desired, the application will be proceeded with.

*Length of Copyright.*—The copyright granted in any of the classes lasts for a uniform period of five years from the date of receipt of application form at the Office.

*Conflicting Designs.*—When an application is made, the Office compares the design with the designs for similar articles previously registered, the term of copyright in which is still running; and if it is found that the design has been anticipated, or if it is obviously an imitation of any such design, the Comptroller will give the applicant notice of the fact, and inform him that he cannot proceed to issue the certificate. If the applicant desires to explain away the similarity, or urge reasons why a certificate should be granted to him, the Comptroller will fix a day for a personal interview, when the applicant or his agent can attend and go fully into the matter.

The Comptroller having heard all that can be urged in its favour, will decide whether or not he can issue a certificate of registration. If he decides against the applicant, an appeal against the Comptroller's decision to the Board of Trade is open, and, after hearing the applicant and the Comptroller, the Board will either endorse the Comptroller's decision, or decide against him, and direct him to register the design.

There is no fee for a hearing before the Comptroller, but if the applicant determines to appeal to the Board of Trade against the Comptroller's decision, a stamped Form F is required, which costs £1.

Of course, none of these difficulties will crop up if the design is a *bonâ-fide* original one.

This procedure acts as a deterrent to the class of imitators who are always ready to copy as nearly as possible the products of the ingenuity of other persons, if such are finding a sale, and acts very much to the advantage of the honest designer or inventor.

*Consents.*—The Comptroller will sometimes suggest where the design differs from some original one to a certain extent—and is yet at the same time evidently an imitation of it—that the latter applicant should procure the consent of the original proprietor, upon getting which, and lodging it with the Comptroller, he will proceed with the registration. The Comptroller will furnish the latter applicant with the original proprietor's name and address, so that communications may be opened for that purpose. In such cases the original inventor can often obtain a *quid pro quo* in exchange for giving his consent, and thus secure some return for the ingenuity which the latter applicant is desirous of taking advantage of. Of course, the proprietor can refuse to give his consent, and then, the Comptroller does not proceed, unless directed to do so as the result of an appeal to the Board of Trade; and if the latter applicant still puts his design upon the market, without making any arrangement with the proprietor of the original design, he can be proceeded against for infringement, and if the courts decide against him, may be ordered to pay damages and costs.

If, on the other hand, the latter applicant thinks he has made no infringement, it is quite open for him to put his design upon the market; but he will have been warned of the risks he is running in so doing.

Here, again, the practice in the designs branch differs from the patent procedure, for patents can be secured for the same thing by as many different persons as choose to apply for them, so far as the Office is concerned, for it makes no search on the question of anticipation; but the patent specifications are all open to inspection for a certain time

before the grant of a patent, to give time for oppositions to be lodged; whereas, the designs, during the term of copyright, are not open to the inspection of the general public without the consent of the proprietors.

*Inspection of Conflicting Designs.*—An exception to this rule of keeping all designs secret during the period of copyright, is made in the cases where the Comptroller informs an applicant that his design has been anticipated. The applicant or his agent can inspect the conflicting design or designs quoted by the Comptroller on payment of a fee of one shilling. This is generally done before a date for a hearing is asked to be fixed. This inspection of the conflicting design will enable the applicant to see how far, and in what respect, he has been anticipated.

*Actions for Infringement.*—This action of the Comptroller should not be considered as altogether final on the question of infringement. A certificate may be issued to the latter applicant, and still the earlier proprietor may feel aggrieved, and can institute an action if he chooses, when the courts will hear both sides, and come to a decision on the evidence tendered. The action of the Office in such cases is not infallible, and the decision arrived at may not be altogether correct from various causes. For instance, the Comptroller may not be in possession of all the material facts of the case, and in dealing with a large number of designs every day, it will be evident that mistakes or errors of judgment may be sometimes made, though every care be taken to obviate such. The issue of a certificate of registration stands on the same footing as the grant of a patent. It does not confer an unchallengeable right, for in either case the courts may cancel them, if it is shown that they have been wrongly issued. This is a point which is often not properly understood by novices in patent matters, who frequently consider when the Office has granted a patent or certificate of registration that their rights are secure and unchallengeable.

I must defer my remarks on the remaining portions of my subject to my next and concluding paper.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### Working Cordage.

SEIZING — SENNIT — FRENCH SENNIT — GASKETS — FLEMISH EYE — GROMMET — SELVAGEE — WORMING, PARCELLING, AND MARLING — SERVING — BELAYING — FAIRLEADER — BELAYING PIN — TOGGLE — FENDER — THIMBLE — MOUSING A HOOK — STROPPING A BLOCK.

To give a complete account of all that can be done with cordage would, in fact, be to write a treatise on rigging, which is altogether outside our present purpose. But there are many ways of using rope for the construction of various articles in constant use aboard ship that every seaman has to acquire, several of which are of great service to landsmen and all those who have anything to do with cordage. Some of the principal of these we shall now consider. Seizing is fastening together two ropes, or different parts of the same rope, with several coils of small rope, spun-yarn, etc., laid on close together. There are several kinds of seizings which take their names from the positions they occupy in the rigging. End seizing is a round seizing at the end of a rope. Throat seizing is the first seizing clapped on where a rope or ropes cross each other. Middle seizing is between a throat and end seizing. Eye seizing is a round seizing next to an eye in the rope. To make a round seizing, make a small eye in the end of the seizing stuff, and, after taking a turn round both parts of the rope, reeve the ends through the eye, take two or three turns, and haul them taut with a marlinespike hitch; pass eight or ten turns close together, and heave taut. Bring the end back under these turns and out between the last two coils, and pass another series of turns on the top of the others, which are called riders, and are not hove so taut as the first turns. There is always one less of the riding turns than of the lower ones. Two cross turns are sometimes taken, passing between the ropes to be joined and across the whole of the seizing; the end is brought under the last turn, hove tight, and secured, if large, with a wall knot, crossed; if small, with an overhand knot, and cut off. Other seizings are done in the same way.

Sennit is a sort of flat rope, made by plaiting ropeyarn or spunyarn together, the outside yarns being brought over to the middle from each side alternately. It must always consist of an odd number of yarns, generally from five to thirteen.

French sennit is braided with an even number of yarns passed over and under every other time.

Gaskets are made of braided cordage in the same manner as sennit. They are used for confining the sails when furled to the yards. They are called arm gaskets when used at the ends of the yards. Bunt gaskets are used in the middle of the yard to hold the bunt of the sail, and quarter gaskets between the middle and extremities of the yards.

A Flemish eye (Fig. 119) is a method of making an eye without splicing. Unlay one strand at the end of a rope; bring the other two strands, just as they are, against the standing part, so as to form an eye of the size required. Lay up the strand which has been unlaid in the intervals in the rope from which it has been taken, only the reverse way—that is, you commence at the end and keep on laying it round until it comes down the standing part and lies along with the other strands. The ends are then tapered, marled down, and served over with small stuff.

An artificial eye is the end of a rope unlaid, and the yarns of which the strands are composed are separated. The yarns are now hitched round a piece of wood the size of the proposed eye. They are then marled, parcelled, and served over.

A grommet (Fig. 120) is a ring of rope made by carefully unlaying one strand from a rope and cutting it off. All the turns must be left in it. Form a ring by laying one part over the other, taking care that the turns coincide with one another. Pass one end round and round, in the lay, until all the intervals are filled up and the ring is complete. The two ends are secured as in a long splice, first with an overhand knot, and then by dividing the strands and passing half of them under the standing part, and cutting off the remainder. Grommets are used for stropping blocks, handles for chests, snorters for the heel of sprits, etc. They are very often parcelled and served to make them look neater. It is easier to make them if the rope from which the strands are taken is laid up hard.

Selvagee (Fig. 121) is a number of ropeyarns fastened together. To make it, drive two nails into a piece of board at a sufficient distance from one another to form the size of selvagee required. Wind ropeyarn round these to form the thickness you wish, and marl them down with spunyarn. They are used to form a neat stropping for blocks, or to go round a spar for fixing a hook to. Fig. 122 shows how a selvagee is employed for fastening a block to a rope. The middle of it is placed against the rope, and the bights passed one over the other, until they come close to the rope, when the hook of the block is inserted.

Worming is filling the intervals between the strands of a rope by laying spunyarn or other small stuff into them. This renders the rope more even and smooth for parcelling and serving. The first end of the worming is securely stopped and passed along one of the divisions of the rope. When it has been carried as far as it is required, it is stopped and laid back down another interval, and then forward along the remaining one, and stopped at the end. To estimate the quantity of serving stuff required for a given length of rope, multiply the length of rope to be served by the number of strands in the rope, and add one-third of the product. The result is the length of serving necessary to do the work. Thus, if six fathoms of three-strand rope have to be served—

| | | |
|---|---|---|
| Length | 6 | fathoms. |
| | 3 | strands. |
| | 18 | |
| | 6 | one-third. |
| | 24 | length of serving. |

Fig. 123 shows at A how worming looks when finished.

Parcelling is done by winding strips of old canvas smoothly round a rope in spiral turns after it has been wormed and before it is served. This is shown at B (Fig. 123). The canvas is generally well tarred before it is used. To secure the canvas in its place it is marled down—that is, some marline or other small stuff is wound round it, which is secured at every turn with a hitch, so that each of the turns is secure and independent of each other. This is shown at B (Fig. 123). The proper hitch for securing the turns is given on a larger scale in Fig. 70 (page 361). In marling down, the coils are never laid close to one another, as in serving, but always at some distance apart. Fig. 124 shows the way a rope is served or covered with coils of spunyarn or other small stuff laid on quite close to one another. This is done with a serving mallet, as shown in the figure. The end of the yarn is first secured by placing it under the first two or three coils. The mallet, after being placed against the rope, has two or three turns passed round the body of it, and another turn or two on the handle. This produces sufficient friction to leave the coils taut as the mallet is worked round the rope by its handle. Another person is required for passing the ball of serving stuff. The service must be put on against the lay of the rope. A rope may be served single-handed by using a large reel for carrying the serving stuff, with a hole in its centre large enough for the rope to run through. This is kept just ahead of the mallet, and the serving stuff comes off the reel of its own accord as required. When the mallet is within a few turns of the end, the turns are taken off it by hand, the end is put through them, and heaved well taut.

Fig. 125 is the way a rope is belayed or made fast by cross turns round a cleat. The cleat is in this case supposed to be lashed to a stay or other rope, but it is often made fast to some part of the vessel.

Occasionally a single hitch is put over the upper horn of the cleat, which makes the rope still more secure. It is often required to take a rope at right angles from one part of a vessel to another. This is done by means of a "fairleader" (Fig. 126). It is merely a block of wood with a hole in it of sufficient size to allow the line to run freely through it. The back of it is grooved to fit the rope it is lashed to. Where more than one line has toggle slipped into it. It can readily be undone by slackening the ropes and putting the toggle through the eye, end foremost. Fig. 129 is another form of toggle, a round piece of wood shaped like a button being used in this case. It has a hole in the centre, through which a rope is passed and the end knotted.

In running alongside a pier-head, or when boarding a vessel in a small boat, it is it and clap an eye-seizing on it, marling it down as shown in the engraving. A lanyard of small cords, such as log-line, is then spliced into the eye, and it is ready for hanging over the boat's side. These fenders are very soft—"plum," as we call it in Cornwall—and last a long time. Fig. 131 is another and a handsomer form of boat's fender. This is made of a centre or "heart" of ropeyarn worked over or grafted with

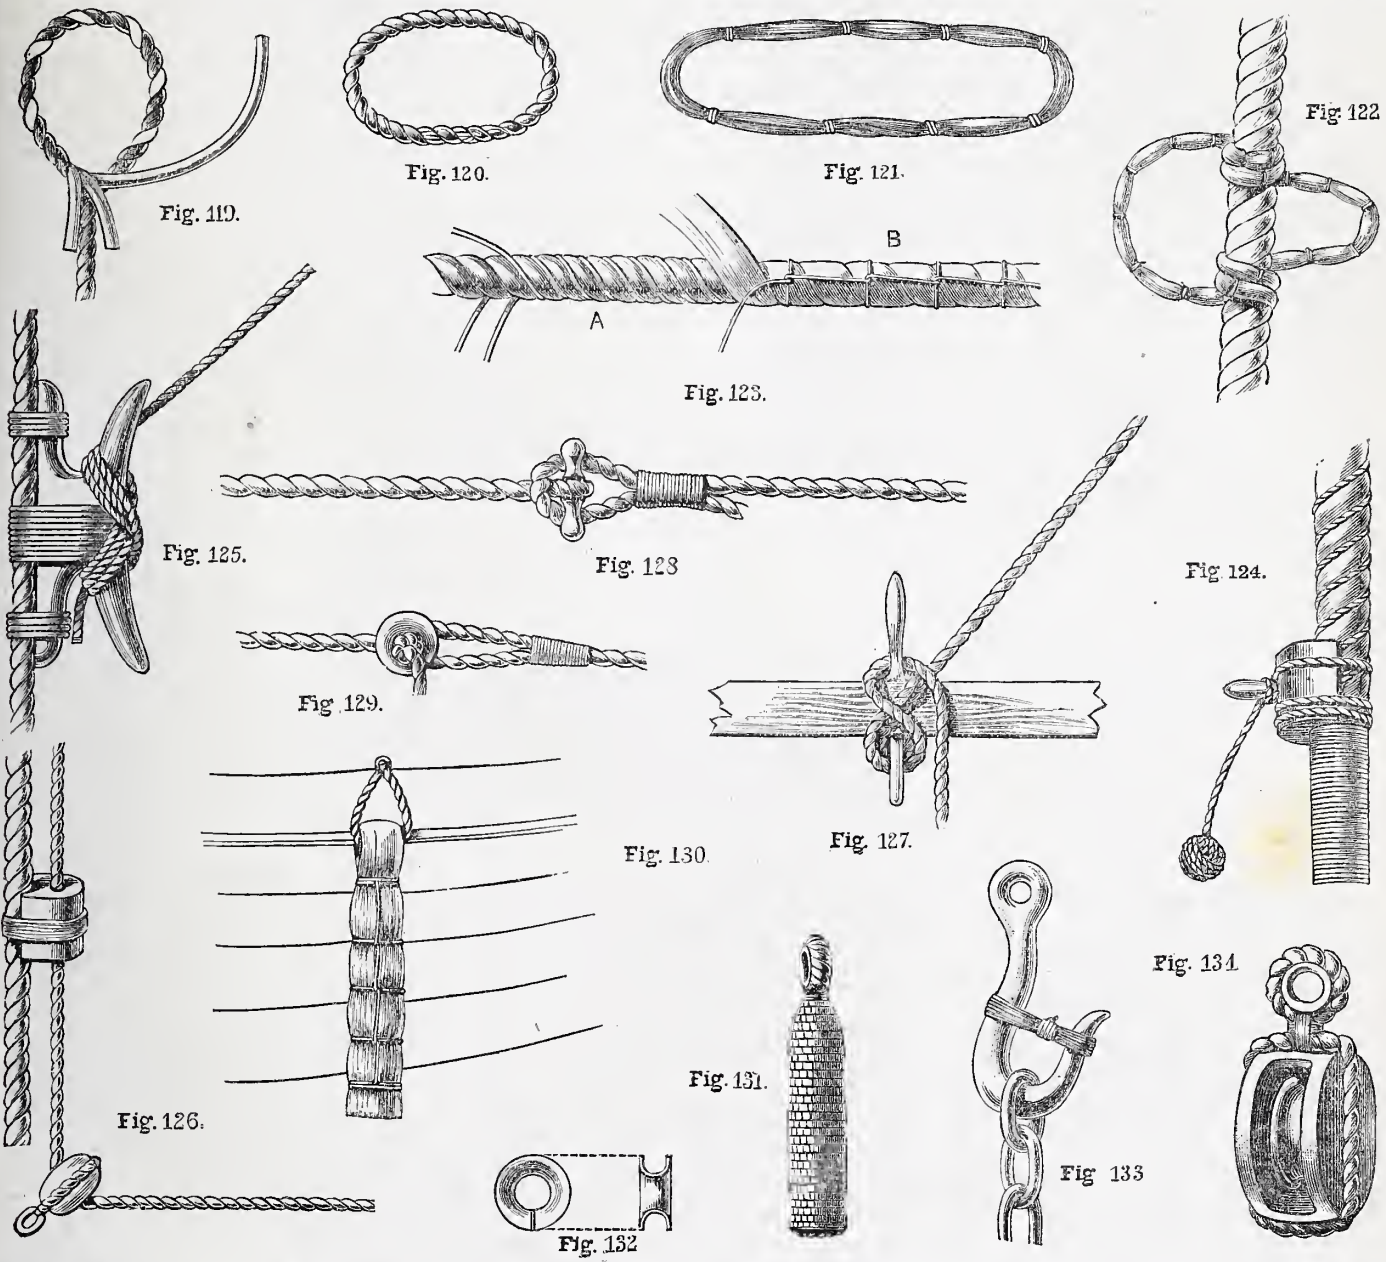

**Fig. 119.—Flemish Eye. Fig. 120.—Grommet. Fig. 121.—Selvagee. Fig. 122.—Selvagee fastening Block to Rope. Fig. 123.—Worming, Parcelling, and Marling. Fig. 124.—Serving. Fig. 125.—Belaying. Fig. 126.—Fairleader. Fig. 127.—Belaying Pin. Figs. 128, 129.—Toggle. Figs. 130, 131.—Fender. Fig. 132.—Thimble. Fig. 133.—Mousing a Hook. Fig. 134.—Stropping a Block.**

to be led, a piece of board or plank with holes through it is used. A fairleader is not necessarily fastened to a rope, but is fixed in that position where it comes in handiest.

Fig. 127 shows a belaying pin with a rope made fast to it. This is the usual way of securing running rigging, as it is made fast and cast off so rapidly. Fig. 128 shows a method of securing ropes together by means of a toggle. This is a piece of wood turned to the shape shown in the figure. It has a groove in the centre, round which the end of a rope is spliced. An eye is made in another rope by any of the methods described and the necessary to have something to protect the boat's sides from being chafed and the paint or varnish rubbed off. These are called fenders. They are occasionally made of wood, which is slung over the boat's side by a lanyard reeved through a hole in the end of it. More often they are made of canvas, stuffed with oakum and painted. Fig. 130 is an excellent form of fender, easily made, very effective, and needs no painting. Take a piece of Manilla rope double the length of the fender required; unlay it, and open the strands; comb them down until all the yarns lie straight; double short pieces of ropeyarn called "knittles" or "nettles," which is in fact a species of weaving. The nettles are first cut to the right length, and the middle part slightly twisted. They are then brought snugly round a thimble, and a seizing put under it. The heart is put into its place and the nettles laid evenly over it. One-half of the nettles, taken alternately, are now turned back over the eye, the rest lying down the heart. Pass a turn or two of twine or marline, called the warp, or filling round the fender where the nettles separate, and hitch it. The nettles that are turned back must

now be brought down, and the ones that are down turned up over the eye. The warp is now passed again, and hitched as before. This must be repeated until the whole of the fender is covered with a sort of woven coat as in the engraving. The ends of the nettles are brought round the last turn of the warp, and interlaced in the grafting. This fender requires a lanyard the same as the last one.

A thimble (Fig. 132), side view and in section, is a ring of iron, usually galvanised, with a hollow formed round it, so that a rope or strop may fit snugly into it. They vary in shape, some being heart-shaped and some round, as in the engraving. They are very much used when a small eye is wanted at the end of a rope for another rope to pass through. Fig. 133 is a method of preventing a chain slipping off a hook, which it would have a great tendency to do when, as often happens, it is dragged along the ground or deck. A few turns of ropeyarn are passed round the end of the hook and the standing part, and the ends brought round the middle a few times, and fastened with a reef-knot. This is called "mousing a hook." For "stropping a block" (Fig. 134), a grommet or selvagee is often used. Sometimes the stropping is made by splicing the ends of a suitable length of rope together. A grommet, however, is neater, and a selvagee the neatest of all, particularly when it is covered with leather. The block is first fixed in one bight, so that the lower part of the block sits on the splice, if there is one. A thimble is put into the other bight, and a seizing put on between the block and the thimble, each turn of which is hove taut with a heaver. The turns are, lastly, crossed, and the ends knotted. Fig. 134 shows the work finished.

## IMPROVEMENTS IN KALLITYPE.

BY L. IVOR POOLE.

INCREASED SIMPLICITY—CLEANLINESS—MATERIALS FOR DEVELOPMENT—VARIETY OF TONE—EXPOSURE—DEVELOPMENT—FIXING—WASHING—ALBUMEN KALLITYPE.

A SHORT time ago I had the pleasure of directing the attention of readers of WORK to the photographic printing process known as Kallitype. Since the article referred to, the proprietors of kallitype have made important progress with their prepared paper, the improvements being of such a radical kind that, as now practised, the process may almost be said to be a new one. The principal reason for the new departure may be stated to consist in the increased simplicity of development, or rather, in the ingredients of the developing solutions. Those who practised the old or original kallitype will remember that, though admirable in its simplicity, and inexpensive, there was great danger of staining the fingers while manipulating the prints. This is now done away, and the process is as cleanly as the most particular could desire. The materials for developing are also cheaper than formerly.

The new paper is known as "Kallitype No. 2," and, like the older form, has a matt surface. Indeed, when developed, the prints look exactly the same as by the older process.

The developing materials are Rochelle salt, borax, and a very small quantity of bichromate of potash; so that it will be seen they are very easily obtainable.

The Rochelle salt—or, as it is called under its scientific name, tartrate of soda and potash—will be familiar to many as a component of seidlitz powders, so that it may be gathered it is obtainable at an ordinary chemist's. It is very cheap.

Borax is too well known to require any remarks, beyond saying that the ordinary commercial kind does very well for kallitypy. On the proportion used along with the Rochelle salt the colour of the prints depends.

The developer recommended for black kallitype prints consists of 1 oz. Rochelle salt, ¾ oz. borax, 10 oz. water, and from 10 to 12 minims of a solution of 20 grains bichromate of potash in water.

By diminishing the above-named quantity of borax to 2 drachms purple tones are obtained, and personally these are more unpleasant to use than the former. That, however, is a matter of taste on which each can please himself, as either the black or purple can be obtained at will, and with equal ease. I presume no one will imagine that the purple alluded to is a bright colour, such as is obtained by the blue or cyanotype process, for it might rather be described to a novice as purple-black.

By omitting the borax, and reducing the Rochelle salt to ½ oz. in 10 oz. water, sepia or brown tones are obtained. When this is desired, half the quantity of bichromate solution, or 6 minims to the 10 oz. of water, is recommended. Many of the sepia-coloured prints are very beautiful, but from some reason, which I am unable to explain, I find it more difficult to produce them with certainty to the same tone. This simply amounts to saying that rather more care is required in the printing.

An earlier formula for producing sepia tones was as follows:—Rochelle salt, ½ oz.; borax, 1 drachm; strong hydrochloric acid, 5 drops; water, 10 oz.; and 10 minims of the bichromate solution. With this also I got some very fine results; but the ordinary formula as given above, being so much simpler, will no doubt meet with more favour.

The prints, of whatever tone, are treated much as if they were on the original kallitype paper. They are exposed in the usual manner till the details in the densest parts of the negative are fairly indicated, and are then kept in the dark and dry till it may be convenient to develop them. The development, if the prints, meantime, are kept from exposure to light or damp, may be deferred for any reasonable time, but what the limit is I am unable to say, as all mine have been done within a few days. For the benefit of those who did not read the former article on Kallitype, it may be said that the prints do not appear fully till development. As the image becomes partly visible, however, there is very little difficulty in determining the right amount of exposure after a short experience. The paper, it may be added, is more sensitive than the ordinary sensitised albumenised kind used for silver prints, but not so much so as bromide paper or any of those used for enlargements or reproduction by artificial light. Owing to its sensitiveness, it should only be handled in a very subdued daylight or by artificial light, but not necessarily that of the dark room.

Over-exposure merely causes too great an amount of blackness in the picture, analogous to the blackening of an over-exposed plate in the camera, while under-printing, of course, gives a weak picture.

When ready, the prints are immersed in one or other of the developers. The print immediately appears, but does not attain its full density for a few minutes. The time considered requisite for full development of a perfect print is stated to be half an hour, but I have found it sometimes an advantage to remove the prints sooner.

It should be noted that if the prints are removed too soon from the developing bath, the yellow tint which is observable will not entirely be removed, as it should be, during the subsequent fixing. On the other hand, if they are left too long in the developer, yellow stains may show on the finished print.

A large number of prints may be developed at the same time, but they should be kept moving, as when toning ordinary silver prints; and the same developer may be used repeatedly if it is kept from the action of light. It is said that 10 oz. of developer will serve for five or six dozen half-plate prints, or, say, a gross of quarter-plate size. In practice, however, I have not been able to accomplish this, or, to be more explicit, have not tried, as, in accordance with the instructions issued with the paper, I have preferred to use plenty of developer. It is so cheap and easily made, that it is better to do so than to run the risk of spoiling prints by using old stuff. A very considerable number of prints, however, may be developed in the same solution without apparent deterioration.

The fixing and clearing, or elimination of the yellow colour, is effected by means of a bath consisting of 4 drachms of the ordinary strong liquid ammonia (·880) in a quart of water—or, say, 1 drachm to a tumblerful. In this the prints should be kept moving for about a quarter of an hour. They may then be washed, but it is recommended that they should be treated in a second fixing bath of the same proportions as the first. This ensures perfect fixing.

After treatment in the fixing bath, they should be well washed, either in running water or in frequent changes, for about a quarter of an hour, though if left in for longer no harm results. They are then finished, and only require to be dried and mounted.

Toning, in the ordinary sense, is unnecessary, as this is done during development, and there is no troublesome washing, as with silver prints, to get rid of the baneful hypo.; so that, on these two grounds alone, kallitype should become a favourite process, especially with those who cannot devote much time to photography, but wish to get finished results as quickly as possible.

There are many to whom the glazed finish of the ordinary silver print is more pleasing than a matt surface, and to meet them, the manufacturers are now issuing albumen kallitype paper. When done on this, the kallitype prints are scarcely distinguishable from good silver prints, without anything like the amount of trouble which there is in producing them. As has been shown, they can be had in almost any tone, including the purple-black which so many amateurs seem to vainly strive to get in silver prints.

Although three formulæ are given for black, purple, and sepia tones respectively, it does not follow that these must be kept closely to; for by carefully altering the various proportions I believe any desired tone—within the range of those given as the extremes, of course—can be got to the utmost nicety. On one occasion, when away in the country, and a long distance from any chemist's where I could obtain developing materials, I developed a batch of prints with a mixture of purple and sepia tone developers. The tone of these is certainly not

inferior to that of any of the others, so that it will be seen no great exactitude is necessary in mixing the developers. The chief point with them is not to use too much of the bichromate solution. This gives greater contrast between high lights and deep shadows, but if used in excess, destroys the half-tones on which so much of the beauty of a photograph depends.

Finally, it may be stated that kallitype prints are considered permanent; and I think that if readers of WORK will try the process they will be, like myself, delighted with its economy, simplicity, and rapidity, as well as with the results.

## SOME LESSONS IN WINDOW MAKING.

BY G. LE BRUN.

### DOUBLE-HUNG SASHES: A FEW NOTES ON THEIR CONSTRUCTION.

DOUBLE-HUNG sashes are so common, and in such general use in this country, that there is scarcely a carpenter's shop of any pretension in which they are not made. But, although this class of window is so common, there are several ways of constructing the framing that is in use in different localities, and even in different shops in the same town, which, although differing in details, have the same end in view—viz., the production of a well-fitting, weather-resisting window that admits of being easily opened and shut. The construction of the building in which the windows are to find a final resting-place often to some extent influences the details of the window case: thus, varying thicknesses of walls, the use of stone or brick, and the kind of inside finishing to be used, either with or without shutters, all affect in a slight degree the various details to be considered in the making of the framing that is to contain the sashes. Added to this, practical workmen differ greatly as to the best modes of doing the work, one man thinking that his particular way is the best to the exclusion of all other ways, forgetting that if the result be a perfectly finished piece of work, without unnecessary expenditure of time, one way is as good as another.

It has of late become the practice in large towns to use to a great extent, especially in cheap or "jerry" work, a good deal of Swedish wood, which can be purchased at the woodyard ready for framing together; thus we find stuff for sash framing, sash bars, sills, sash and parting beads, ready to the hand of the builder who desires to minimise the cost of labour, and who can buy the said stuff in lengths to suit. I am not in favour of this mode of working, however cheap it may be, and in the course of this paper will adhere to the good old-fashioned way of working all the material required out of the rough. Various woods are used for the purpose of window making, from white pine to oak or mahogany. Perhaps the best woods to use, and the commonest for good work, are either red pine or pitch pine—preferably the latter, from its good standing qualities. The inner facings (or linings, as they are sometimes called) may be of yellow deal.

A hung window, when finished, presents the appearance shown in Fig. 1, and to proceed with the construction of it, we must get out our wood. Let us say, for example's sake, that the opening which we have to fit our window to is 6 ft. by 3 ft. "daylight"—that is, exclusive of the rebates: we will then want a sill 3 ft. 9 in. long, 7½ in. wide, and 3⅛ in. thick at one edge, tapering down to about 1 in. at the other. A section of this sole in the rough is shown at Fig. 2, and it must be worked into the shape shown in section in Fig. 3. The groove shown on the under-side is to assist in holding the bedding of cement it will get when put in its place, so as prevent rain water being driven underneath by the force of strong winds; the groove on the inside edge is for the insertion of the edge of the inside finishing piece, although in many cases this will have to be omitted. The bead run on the top of the inner edge is ⅝ in. When the sole is worked out to section, it is best to make a mould of thin wood that can be applied to each end of the sole, and draw on it with a pencil; this will ensure their being all alike, and greatly facilitate matters when you come to fit your sashes in the case. This especially when you have more than one window to make.

The next piece is the lintel; this will be of the same length as the sole—6¾ in. wide and 1½ in. thick. A groove, ¼ in. deep, is run on the under-side, 2¼ in. from the outside edge, for the reception of the parting bead; this groove is $\frac{9}{16}$ in. wide. This groove is shown in Fig. 4, which is a section of the lintel, complete, showing sash bead, parting bead, and outside facing in position. A groove is sometimes run in the inner edge to receive the edge of the finishing board, as previously described in connection with the working of the sole.

There are, as I have previously mentioned, different methods of constructing the sides of the window case. Of these methods one of the simplest is that shown at Fig. 5, and we will follow it in the construction of our window. At the same time, as it is always well to know different ways of doing the same thing, two other methods are also shown in Figs. 6 and 7, in which the principal difference is that they are so framed up that the weights (W) are enclosed in wooden boxes. Whether or not this is an advantage is pretty much a matter of opinion. Personally, I do not see much advantage in thus boxing the weights, and in practice have never found that weights, when unboxed, were liable to entangle their cords. Still, these extra parts serve to stiffen the window case, if nothing else, and in some localities are very generally adopted.

The pulley stiles for our case are cut out of 1 in. stuff, and are planed up true on one side and both edges, being gauged to a width of 5¾ in.; their length (in the rough before cutting to size) is 6 ft. 1 in. Groove them from the outer edge for the reception of the parting bead with the same plough as used for the lintel. A pair of inside linings (or facings, as they are sometimes called), 6 ft. 3 in. long and 5 in. wide, of ⅞ in. stuff, and a pair of outside linings of the same length, 3 in. wide and ⅝ in. thick, are also required. A ⅝ in. bead is now run along one edge of the outside linings, and also on the edge of a similar piece, 3 ft. 1 in. long, which is to be nailed on the outer edge of the lintel, A (Fig. 4).

Take a piece of stuff, 6 ft. long and ⅝ in. thick, free from knots, run a cutting gauge, set to 1 in., along both sides, then run your ⅝ in. bead-plane along the edge, break off the piece, and you have one parting bead; make another, also a piece for the lintel: then shift the cutting gauge to 1½ in., and run off the sash beads (sometimes called bâton rods) in a similar manner. If you do not possess a cutting gauge, a rip saw can be used, but a gauge is the proper tool, as it is a great saver of time. Plane up the rough edges of the parting beads, but leave those of the sash beads until you come to fit the sashes to the case.

The wood thus all prepared, the setting out of the case may be proceeded with. We begin with the sill: lay it on the bench and measure off 3 ft. in the centre, leaving an equal length of wood at each end. Mark and square across the upper side and inside edge, and cut down with the tenon saw to within ⅞ in. of the bottom of the sill; make two other cuts to the outside of the first, and on the angle, the distance from the first cuts being about 1½ in. at the inside edge, and 2 in. at the outside edge, of the sill, so as to give room for driving a wedge behind the pulley stile when fitting together: then off the inside edge of the stumps cut away the thickness of the inside facing. These cuts are shown in Fig. 8 (A, A), in which the finished sole is shown.

The lintel of the case is set out to the size in a similar manner (Fig. 8A), and is cut away like the sole for the reception of the facings.

The pulley stiles are cut ½ in. shorter than the "daylight" of the brick or stone opening, which in this case is 6 ft., so their exact length will be 5 ft. 11½ in. By referring to Fig. 9, the mode of cutting the pocket-hole for the insertion of the sash weights will be seen. Pocket-holes differ in length according to the size and weight of the sashes. Thus, a sash glazed with plate-glass weighs heavier than one glazed with sheet, and so requires larger and heavier weights; therefore the pockets must be cut to suit. This is, however, a matter of detail, and it will be sufficient for our purpose if we make the pockets of the case we are working upon of a medium size—say, the lower end about 9 in. from the case sole, and the pocket itself about 1 ft. 6 in. long. In the figure you will notice that one end is cut at an angle; this is the top end. Cut from both sides of the stile, a trifle more than half-way through, with a finely set dovetail saw, bore two holes with a small centre-bit in the middle of the groove of the stile (Fig. 9, A A), and rip down between them, using a port saw to commence the cut. Do not knock out the pieces just at present; that is done in putting the case together.

The insertion of the pulleys in the stile next claims our attention. They should be put in about 4 or 5 in. from the top end, and in the centre of each sash run, being sunk flush with the wood, and carefully fitted in, as if they do not fit well and firmly, they will work loose in time with the working up and down of the sashes. See also that when fitted the wheel runs easily and does not jam. When many cases of the same kind are being made, it is usual to make a mould with two square holes in it, so that, when applied to the top of the pulley stile, the holes can be marked round with a pencil, and thus show where to cut away without measuring. This mould ought to have a piece of wood nailed along one side and end to serve as a guide, or fence, in applying it to the stile.

The various parts of the case being now ready for putting together, take the inside facing and nail them on to the inside edge of the pulley stiles, taking care not to nail the pocket piece, which, if done, would cause much profanity when you came to knock it out. These facings are not as yet cut to length; that is done in finishing the case. Lay the stiles on the bench, the facing over

the edge, and clean off with a fine-set hand plane.

To put the case together, clear the tools off the bench, and lay across it two pieces of wood rather longer than the case is wide, and of any reasonable width and thickness—about 5 in. by 2 in. is a fairly suitable size. Lay on these pieces the stiles, facings downwards, then place the sill and lintel in position, and fix them so with wedges driven in behind the stiles as shown in Fig. 10, A being the wedge. When firmly wedged, and the joints quite close, secure the case further by nailing the sill and lintel firmly to the stiles with 3 in. nails. The outside edge of the case is now uppermost as it lies on the bench, so before turning it over put on the outside facings, first making sure that the case is perfectly square by trying it diagonally with a pointed rod. The lintel facing is put on first, and allowed to project inwards $\frac{5}{8}$ in.; the side facings are then fitted on and nailed firmly. These facings are sometimes mitred at the corners for the round of the bead, and just as often the side facings are fitted to the lintel facing with a gauge. The case is now turned over, and if the joints on the inside are not perfectly close, a cramp is applied, and the inside facings nailed firmly to the stumps of the sill and lintel. With a smart blow from a hammer behind the bottom ends of the pocket pieces, they are knocked clean out, then replaced in position, and the parting beads fitted in, the lintel piece being put on first, and nailed. The side beads are not nailed, and must fit tightly in the groove, the lower end being cut so as to fit the bevel of the sole, and having a small tenon that will slip down behind the end of the sole and into the groove. The top ends are fitted to the lintel bead with a gouge. The sash beads are now put in, lintel first, as before; then the side beads. The lintel bead is nailed, and is stripped to the proper width before being put on; the side beads are not stripped to width until the sashes are fitted in: they are temporarily held in place by a fine brad driven half way in. Fig 11 shows mode of mitring the corners of these sash beads.

The inside facings, sill, and lintel are now finished off with hand-plane and sandpaper, the stumps of the linings cut off, and the case is finished and ready for the sashes. In many shops a pair of trestles are used for laying the case on while putting together, instead of using the bench for that purpose, but that is a mere detail.

The making of the sashes comes next, and as all the practical details of an ordinary sash have been described in a previous paper, it will be sufficient to call attention to a few points to be attended to in the making of sashes that are hung, the principal difference from the sashes described being the "meeting bars," "chess bars," or "countercheck bars," as the top and bottom sash rails that meet in the centre of the window are called: they have a host of other *aliases* besides these terms, but for our present purpose we will call them the "meeting bars"—it is quite as sensible a term as any of the others. These meeting bars, then, seem often to be the bugbears of the aspiring young carpenter: he is troubled in his mind about them when he gets a hung sash to make, and their perplexities cause him sleepless nights. Why this should be so is a mystery, for a little thought over them ought to be sufficient to clear the brain, and enable it to comprehend their intricacies.

Fig. 12 shows a section of the case and sashes. To set out the sashes accurately, cut a rod the exact length between the lintel and the part of the case-sole where the bottom of the sash-sole will come when fitted—that is, close to the foot of the parting bead. Set out on the rod the width of the sash-sole, say $3\frac{1}{2}$ in., and that of the top rail of the upper sash, say $2\frac{1}{2}$ in.; divide the space between these into two equal parts (sometimes the upper sash is made shorter than the lower), and set out there the meeting bars, $1\frac{1}{2}$ in. This now gives the length of the sashes, the lower one being from the bottom end of the rod to the *upper* side of the meeting bars: the upper one, from the top end of the rod to the *lower* side of the meeting bars. These lengths are shown by the dotted lines outside Fig. 12. In Figs. 13 and 14 the mode of tenoning and rebating

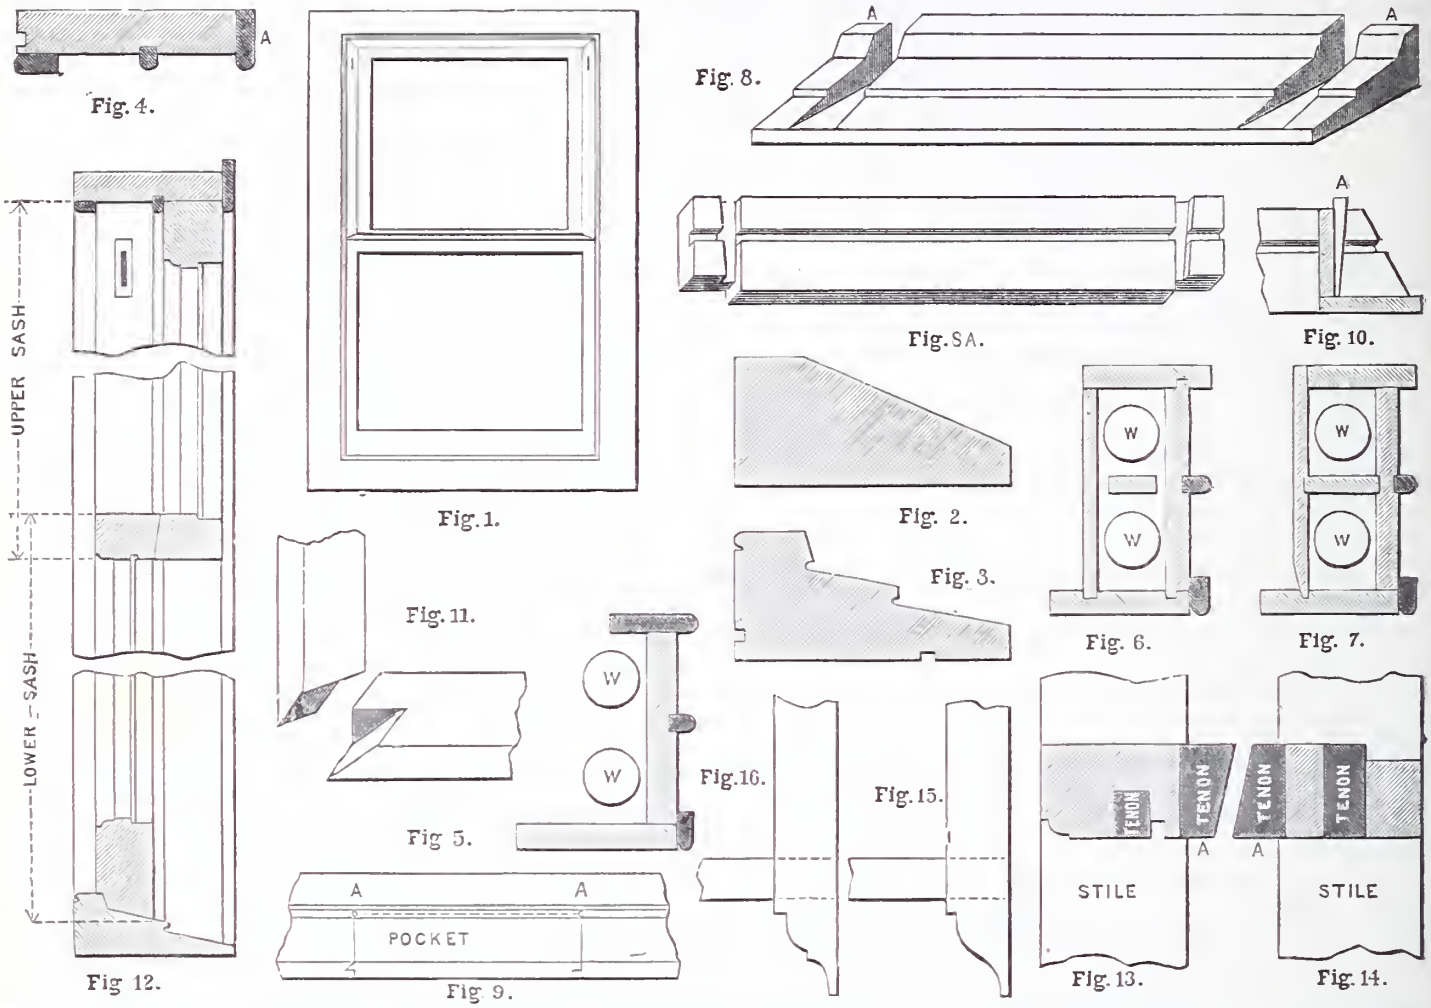

**Fig. 1.—Elevation of Case with Hung Sashes. Fig. 2.—Section of Case Sill in the rough. Fig. 3.—Section of Finished Sill. Fig. 4.—Section of Lintel. Fig. 9.—Method of cutting Pocket Pieces. Fig. 10.—Method of wedging up Pulley Stiles. Fig. 11.—Mode of mitring Sash Beads. Fig. 12.—Section of Case with Sashes. Figs. 13 and 14.—Sections of Upper and Lower Meeting Bars. Figs. 15 and 16.—Alternative Mouldings for Stumps of Upper Sash.**

the meeting bars is shown, Fig. 13 being the bar of the lower sash, in which it will be seen that instead of a rebate for the glass, there is a groove run (the reason for which will be obvious), and that the tenon going through the stile is only half the width of that in the upper bar. This is because a moulded stump is generally left on the upper sash, while that of the lower being cut off, the tenon, of course, must be smaller accordingly. Sometimes, in good work, the stump is also left on the lower sash, and in that case the tenon can be the full width. Two alternative shapes for these stumps are given at Figs. 15 and 16. Fig. 14 shows the upper bar, in which there is only the rebate for the glass run, no moulding being required. Besides the ordinary tenons on these two bars, the extra width of them allows of an additional tenon, as shown at A A in the figures. There is a piece about ⅛ in. cut out of the stile to allow of greater steadiness to these tenons, as also shown.

In getting out the wood for these meeting bars, ½ in. wider than the thickness of the sash stuff should be allowed, and one edge only should be planed up, the other being left rough until they are fitted. I think these few explanations should be of sufficient assistance to those who have studied the previous paper, and should enable them to grasp the various details, all the setting out of the rails, the mortising, moulding, and rebating having been there thoroughly gone into.

When the sashes are made and finished off, there remains the job of fitting them to the case. To do this, proceed as follows: Place the case on end against the wall of the workshop, and try if it is quite square by means of the sash beads, which you will take out, applying them from corner to corner. If not square, you must get it so by squeezing the long corner a little, and when right keep it so by means of a piece of wood nailed diagonally across the case on the outer side. Of course, you will keep the inside of the case towards you. Cut off the stumps of the lower sash stiles, and bevel away the lower edge of the sill rail to fit the case sill, using a skew plane to form the inside rebate. Make a good fit, as an ill-fitted sole is an abomination. When fitted, plane up the top of the meeting bar, then putting the sash in its place, measure with a rod the distance from the lintel to the *under* side of the meeting bar: take the distance at both sides of the case, as there might, from some cause or other, be a slight difference. Apply the rod to the upper sash, the end flush with the *under* side of the meeting bar; mark off the height on each stile and strip up to size. The meeting bars are now bevelled, to fit tight against each other, in the way shown in Fig. 12. Sometimes a special plane is used for this purpose that forms a double rebate and prevents the opening of the sash fastener by means of the insertion of a knife from the outside, a mode of entrance that is familiar to the enterprising burglar; but the common way is a simple bevel joint as shown. Of course, it will be apparent that space for the parting bead to work in must be cut from the ends of the bars. The sashes when fitted should not have too much "play" sideways—not more than $\frac{1}{16}$ in. each side. After the fitting is completed, grooves must be run in the outer edges of the stiles for the reception of the cords, using a ½ in. plough-iron, and making the grooves ½ in. deep. Run these grooves from the top edges of the sashes, and fully half-way down the stiles. The sash beads can now be stripped up to the proper width, which can be found by putting them in place and sliding the lower sash up and down, allowing, of course, a little clearance. If you have more than one window in hand at one time, the sashes must be numbered so that they may be put in their proper places when glazed. The numbering is generally done with a ½ in. chisel, Roman numerals being used, and the numbering done on the bevel of the meeting bars, and behind one of the sash beads of the case, in this fashion —IX.

I have thus given a few necessarily short hints to the novice, and trust they may be useful in aiding him a little in the mysteries of hung sashes, and again remind him that there are many and various ways of working, as well as the way described, and advise him to get on friendly terms with the older hands in his shop; they will, if properly drawn out, give him many a wrinkle, and teach him more by verbal explanation than he can ever hope to learn from a short paper like this, however clearly it may be written.

I need scarcely add that the mode of constructing the case sides shown in Figs. 6 and 7 demands slightly different treatment of the ends of the case sole and lintel; but the difference is of such a nature that the proper treatment will suggest itself to the intelligent workman.

## AN EASILY-MADE MACRAMÈ BOARD.

BY PASQUIN.

By reason of its virtually everlasting qualities, macramè lace is always likely to be popular; hence there are probably many persons who would practise this elegant and fascinating art were a really good and easily contrived frame or board to be had at a reasonable price. The one herein described can readily be made by anyone who can handle tools, while the cost is a mere nothing. It is simple in its construction, and possesses many features likely to recommend it to already skilled workers in macramè, two of the principal of which are —the ease with which the foundation cords may be strained taut and kept so, and the simple but effective contrivance for holding the strings for certain stitches. "Solomon's knot" is a case in point. In this stitch it is almost imperative that some such contrivance is available. Some persons loop the two strings which form the basis of the "bar" (and upon which the stitch is worked) through the vest buttonhole, but this is obviously a makeshift arrangement, as the body must be held rigid, or the cords are slackened. In page 430, "C. E. M." gives us an arrangement designed with the same object, but although he succeeds in holding the strings fast enough, they are level with the board, and are consequently awkward

to get round. Further, his contrivance requires opening and shutting, or the use of both hands, whereas in the one I am about to describe, a single simple motion of the hand, as in laying down the cords in question, is all that is required; while they are rigidly and firmly held in any position, and as far from, or as near to, the board as may be deemed desirable. The board I made was of inch stuff, and has since been put to other uses; hence I am unable to furnish exact dimensions, nor does this matter, as very few are likely to attempt a piece of work over six or eight feet in length, and such a piece could be comfortably worked on the size I have here given. As for width of the board, that is really immaterial—any width sufficient to include all the foundation cords will do. However, I have given the dimensions of the one I first made, as nearly as I can remember them. Take, therefore, a piece of inch board, planed up on each side, and of any approved size. First, by means of good paste, cover one side with clean brown paper. This is convenient in several ways: it allows of marking out distances, etc., and also serves to keep delicate coloured string clean. I first mapped out the face of my board into squares of an inch, and at the intersection of the lines I bored holes to receive pins, made from cheap button hooks, with the hook filed off. These I expected would be of service in working deep designs, but beyond utilising such pins and holes to hold work out of the way, I never made much use of them. Probably, however, one line of such holes, at about a third of the way up, would still be found useful, and two such pins as those described would be plenty. Having got out your board proper, proceed to make a base or stand, which may be of half-inch stuff, but must have a stay or cleat screwed on at each end, or nearly; this not only prevents warping, but also serves to keep the appliance steady on the table when in use. Get a piece of old broomstick, and cut two such pillars as are shown in Fig 11, taking care to have the bevel the same in each. These support the board in front, as shown in Fig. 1, while a plain bracket, cut as Fig. 12, supports it at the back. Two such may be used if desired, but one is quite enough to secure stability. Now before putting up the board, affix a stout piece to the right-hand end, to serve as a peg-block. Fig. 10 shows such a block, which may be made the full width of board, if desired, but in practice, I found that only the first two foundation cords required to be perfectly taut; all others can take care of themselves. Bore the peg-block to receive a couple of ordinary 'cello pegs, and at the corresponding part of the other, or left-hand end of board, insert two screws, or even wire nails, to serve as "hitch pins." But even with all the force obtainable from the pegs, the foundation cords will still be far too slack; besides which, they are level with and touching the board. Therefore we make use of two bridges, such as Fig. 2, one at each end. These are carefully raised *after* the foundation strings have been well strained, and you will find the latter become as taut as wire, and remain so for any reasonable time. Next, procure two common cast- (or malleable) iron blind brackets, such as are shown in Fig. 4 These, I believe, are of American make, and are to be had of any ironmonger. Fig. 4 is about the actual size, and these are used to support the rod which is shown in Fig. 1. This rod I bought at a veneer shop in Birmingham, and these also are of American origin. I think the wood is birch, and the rods are about three feet long, and are turned in several sizes. You require one of half inch diameter, as its use is to hold the clip, which, when you buy it, is like Fig. 6. Simply bore the ends of the rod sufficiently to take the nose of the brackets, as in Fig. 9; then, having firmly fixed one of the brackets, and also the other, with the exception of the outer screw marked with the cross, spring into place and screw up. These brackets, of course, are affixed on the *front edge* of the board. Next, get your clothes-peg, as in Fig. 6, and file up so that it will grip the rod, as in Fig. 7. Then, with a tenon saw, cut a clean kerf, as in Fig. 8. This kerf comprises the whole tool, as two or three strings may be held by it, while the clip runs on the rod with friction; hence any position or angle may be retained. The diagram, Fig. 13, shows the relative positions of base, board proper, rod, clip, bridge, and strings being held.

Having used this handy little contrivance for many months, during which I worked some of the most complex designs, I can recommend it as of as much use as a third hand. Those who have wrestled with macramè on the flat can have no idea of the comfort with which one can work when the board is tilted to an angle of 45°, and although the entire board as here given requires space when not in use, its great solidity and practical value cannot fail to be appreciated by all who try it. Of course, the board might be made to fold up flat with its base, or the latter be dispensed with, but as this would be at the expense of stability, a prime consideration in this work, I for one shall stick to the fixture.

I may add that at first I made a pair of rollers for each end; one on the top, and the other under. These were fixed with similar brackets, but those having an *eye* instead of a *slot*. My idea was to work, say, 4 ft., and then to roll that under and work the remainder. In theory, this was fine, but practically it did not "gee." There was the difficulty about getting the foundations tight, and I discovered that it was as easy to take the work off the board, take a good grip through the pattern, near the foundations, with drugget pins, and "belay" afresh. For such, however, as may wish to try this dodge, I may say that about an inch must be cut out of each end of the board, leaving projecting lugs on which to screw the brackets, and that the latter are affixed on the face and under-side of the board, and not on the edges. With these rollers pegs are inadmissible, but bridges may still be used. A useful tip for macramè workers is: Don't bother to count the stitches; use callipers instead. With care, these will always measure to a half stitch, provided the work is evenly done.

## OUR GUIDE TO GOOD THINGS.

**** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 101.—Tolhurst's Heat-Resisting Mastic Paints.

These paints, which are highly spoken of and warmly recommended by those who have used them, are made, as their distinctive name implies, from prepared mastic, known as "Patent Mastic," and have the merit of being entirely free from white and red lead or any other poisonous ingredients. They are ground as fine as enamel, and are therefore as suitable for all kinds of decorative work within doors as they are for outside work. Further, they are specially suited for hot climates, as they will resist all action of the weather, from the intense heat of tropical climates to the vigour of the depth of winter in the Arctic and Antarctic regions. In addition to these good qualities, it is claimed for them: (1) that they are comparatively inexpensive; (2) that they possess covering and penetrating qualities to a greater extent than any lead or oxide paints; (3) that they are extremely durable, and remain, when applied to any surface, in a sound and perfect condition for many years; and (4) that, owing to their heat- and cold-resisting properties, they will not crack or blister under any circumstances. For these valuable qualities they cannot fail to commend themselves to engineers, tool-makers, boiler-makers, contractors, railway and steamship companies, ship-builders, gas and water companies, etc., for whose use, indeed, they are specially prepared. They have an especial affinity for iron, and penetrate with ease the smallest pores, thus affording complete protection against the deteriorating and oxidising influences and action of the weather. Sample tins of 1, 2, 4, 7, or 14 lbs. may be had and prices may be ascertained by application to the manufacturers, Messrs. Tolhurst & Son, whose offices are in London, and whose precise address may be obtained by reference to Kelly's London Directory. I have frequently been asked during the last ten years what paint or enamel would be most suitable for model engines in virtue of its durability and heat-resisting properties, and I have not been able to name any paint in ordinary use which would fairly answer the purpose, and present a hard and permanent surface when dry. It seems to me, however, that the difficulty may be met by the use of these paints, of the existence of which I was unaware until a short time ago, and which I am now inclined to recommend for the purpose mentioned. This firm also manufactures and supplies an equally good steam joint mastic; excellent non-poisonous mastic enamels; gasholder paints, especially prepared for submerged surfaces, and drying quickly with a fine gloss; flat paints, which also dry quickly with a perfectly dead surface, and quick drying funnel paints. Of these the non-poisonous mastic enamels must be applied with a soft, clean brush, until they have ceased to flow, and if found to be too thick for any kind of work they may be thinned with enamel thinnings. They dry quickly—so quickly, indeed, that two successive coats may be given in one and the same day—and present, when dry, a firm, hard, glazed surface, resembling the glaze on porcelain or earthenware, thus obviating any necessity for varnishing. With regard to the steam joint mastic it is pointed ont that 1 cwt. of it is equal in bulk to 1¾ cwt. of red or white lead. The directions for its use are as follows:—"Roll in the hand a piece the size required, and with the aid of a portion of hemp or twine (if considered necessary) proceed in the same manner as in making a lead joint; if possible, it should be made while hot—that is, unmade and made while working, and the pipes almost too hot to handle and wiped perfectly dry. After the joint is made put pressure on gradually." These paints and other kindred substances, into whose preparation the "Patent Mastic" enters, although they may be well known in the trades in which they are used, are not known so widely as they should be by amateurs. For example, I must confess that they were not known to me until my attention was called to them by a friend of the proprietor and patentee. Bnt to me their value is now fully apparent, and I do not hesitate to recommend them for the purposes indicated above. A card of the various colours in which the paints are made will be supplied to applicants with price list upon enquiry of the manufacturers, whose name is given above.

The Editor.

## SHOP:

### A Corner for Those who Want to Talk It.

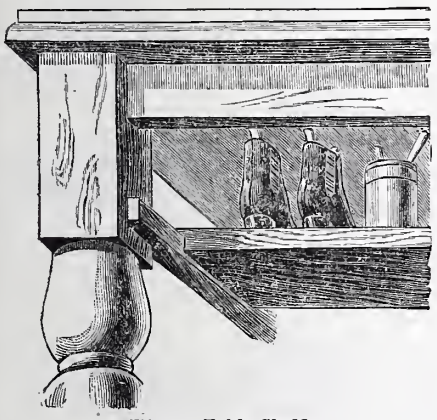
*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Testing Accuracy of Framework.**—J. C. K. (*London, W.*) writes, in sequence to J. S. and G. P. (see pp. 507 and 523):—"As we differ on a very clear matter of fact, and every process of a reliable mode of testing accuracy of square or right angles of framing, and as it is one of the simplest operations in mechanics, I am content to leave it to the judgment of those workers who have to test for squareness of their work. It is needless to repeat the same arguments; I will simply add that, if the square frame is winding, the diagonals being alike for length would prove the frame was not square at two angles. I have had to point this out to learners under me, and in surveying on uncertain levels, it would be misleading if ever attempted, and be no proof. Why Euclid is referred to I do not know. The laws of Euclid would prove my contention that same length diagonals may indicate a trapezoid. If the opposite sides of a picture-frame are equal, and the angles square, no other test is wanted for accuracy."

**Kitchen Table Shelf.**—A. B. (*Salford*) writes:—"The annexed sketch represents a shelf fixed between the legs of an ordinary kitchen table, where it will be found useful for the disposal of boots, blacking-brushes, and other articles. The bearers are notched and screwed to the table legs;



Kitchen Table Shelf.

the shelf is rebated at the ends, and rests loosely on the bearers."—[Thanks for the suggestion, which will no doubt be serviceable in its idea. Boots and blacking-brushes, however, would be replaced by some more wholesome articles in my household. —Ed.]

### II.—Questions Answered by Editor and Staff.

**Work Exhibition.**—A. M. L. (*Bedworth*).—There will be no Exhibition again for the present; but if you have any novelties, let us see them on approval for Work.

**Photography.**—G. C. (*St. Blazey*).—Always consult the indexes of Work, Vols. I. and II., when you wish to learn as to the past contents of the publication.

**Chemistry.**—H. B. H. (*Leicester*).—The best book for qualitative analysis is Clowes' "Practical Chemistry," published by J. and A. Churchill at 7s. 6d.; and for quantitative analysis, Thorpe's "Quantitative Chemical Analysis," published by Longmans, Green & Co., at 4s. 6d. The best plan is to thoroughly master qualitative analysis before starting the quantitative. If Clowes' is too expensive for you, Thorpe and Muir's "Qualitative Chemical Analysis," published by Longmans at 3s. 6d., is a good book, although I prefer Clowes'.—F. B. C.

**Brass Moulders.**—J. B. (*No Address*).—The only flux we ever use is a piece of yellow soap, say, as large as a five-shilling piece, put into an average-sized crucible, and stirred well into the metal, just before pouring into the mould.—J.

**Electric Night-Light.**—Frisky.—Lamps of 5-candle power may be had from vendors of electrical materials. In your town they may be obtained of Messrs. King, Mendham & Co., Narrow Wine Street and Fairfax Street. These lamps are made to work with current from batteries of various sizes and types, and are numbered to indicate the voltage of the current required to light them. By this system we are able to choose a lamp to suit a selected battery, or a battery to suit a selected lamp; lamps of 5-c.p. range in voltage from 5 volts to 65 volts—that is to say, their filaments offer a varying resistance, requiring these variations in the voltage of the current to light them. To light a 5-c.p. lamp we must first know the voltage required to light it, and then choose a battery giving the required voltage. Suppose we have an 8-volt 5-c.p. lamp to light with current from a battery: the battery must give a current having an E.M.F. (electro-motive force) of 8 volts. The highest E.M.F. obtainable from one cell of the bichromate or chromic acid type is 2 volts, so we shall need four such cells connected in series to form the battery of this type for our lamp. The E.M.F. of a Leclanché cell is 1·60 volts, and that of a dry cell from 1·50 to 1·55 volts. We shall therefore require six cells of either of these types to light the lamp. You will therefore see how wide your question is respecting the number of cells it would take to light a 5-c.p. lamp. Now as to the best battery for the purpose. A few months since I should have said there is only one battery suitable, and that is the chromic acid battery. I find now that there are several batteries more suitable for night-lights in the bedroom than the messy chromic acid or bichromate of potash batteries. The large size six-block agglomerate Leclanché cells are preferable, because there is no offensive odour from them, but they cost from 9s. to 10s. 6d. each cell. The ordinary Leclanché of large cells, costing 4s. 6d. per cell, has been used, and I have a correspondent who used such a battery. On the 27th of October, 1890, he discarded the Leclanché, at my suggestion, for a battery of Gassner dry cells, and he writes: "I have had no further trouble. They have not been touched since, and apparently are now as good as the day I started them. One night I left the light on by mistake. By morning the battery had run down. In twelve hours it was usable again, and in forty-eight as good as ever." The Gassner is retailed at 4s. 6d. per cell, but there are other dry cells besides this one. I have now an electric lighting night-light set, sent on approval for trial by the Electric Stores Company. This set is furnished with four E.S. dry cells and a 4-volt lamp, watch-stand, etc. The lamp will light up the face of watch and show the time on pressing an ordinary push-button. The lamps cost about 5s. each. The current can be switched on and off by an ordinary switch.—G. E. B.

**Fire-Boxes.**—J. H. (*Hunslet*).—We are gratified at the appreciation of our labours expressed in the communication of our correspondent, and have given his suggestion our careful attention and consideration. As it is our wish and endeavour to place before our readers and subscribers such information and instructions as will enable them to carry out such matters with the *ordinary* means at their disposal, we are satisfied that any instructions or information we might give on the subject referred to would be of no practical use, inasmuch as to perform work of the kind is out of the power of the general run of our readers. For instance, the following plant and tools are needed for the work: Rolls to take the buckles out of the plates; a slab on which they are trued; drills and cutters for making the holes for the rivets, stays, and tubes; screwing machine for threading the stays between the inner and outer boxes; taps for threading the holes in the plates; reamers for truing the holes for the rivets; a tube expander for tightening and fixing the tubes in the plates; a set of caulking tools for the joints; flogging and hand hammers for caulking and riveting; holding-up hammers and a "dolly" for the riveters; a rivet forge for heating the rivets; a smith's forge; a die, snap, or cup for forming the ends of the rivets, and if they are "countersunk" then there will have to be a countersink for so forming the holes; also chisels for cutting off the ends of the rivets in the old boxes, and punches or drifts for driving out the old rivets; besides many other small appliances and conveniences usually found in well-appointed boiler shops. Added to these are required the services of *skilled* workmen to set out the plates and do the work in the proper way; it would have to be done to make it a sound and *safe* job. We think from this our correspondent will be able to judge how far any instructions and information we might give would be of *utility* to our readers. That they would be *interesting* we do not doubt. We should not advise any of our readers who have not been *practically* trained in such matters to attempt to meddle in them. New fire-boxes are put in by the makers of such engines at such a reasonable price, that it would be the height of folly for anyone not qualified to attempt it, and the owner of such an engine requiring such repair should at once send it to the maker whose name and number appear on the plate attached to it. It is not our desire to lead any of our readers into trouble, or afford them facilities for getting into it.—C. E.

**Patent.**—J. B. T. (*Manchester*).—You cannot patent an *idea*. On application to the Patent Office, Chancery Lane, London, E.C., you can be supplied with printed forms.

**Clarionet Reeds.**—F. J. O'C. (*Dublin*).—You cannot do better than apply to Besson & Co., Euston Road, London.

**Prizes for Competition in Work.**—J. L. (*Bradford*).—We have already given prizes to readers of Work for bookcases, and doubtless there will be further competitions on a more extended scale.—Ed.

**Colouring Brass Work.**—J. P. (*Birmingham*), referring to a receipt given at p. 779, Vol. I., asks how I make my chloride of antimony liquor. As a matter of fact, I do not make it at all, but get it at a chemist's; but chloride, or butter, of antimony, is obtained by dissolving crude or roasted black antimony in hydrochloric acid, adding a small quantity of nitric acid. You are right in supposing that articles may be bronzed by dipping in the ordinary way. My remarks, as quoted by you, were, if I remember aright, made in reply to a query, asking how to colour the brass ferrules, etc., of fishing-rods; and I, therefore, recommended what I think the most satisfactory method.—Opifex.

**Polishing Marble.**—J. M. (*Paddington*).—The usual plan is to lay the slab flat, and first rub it down, if necessary, with a coarse grit. The rubbing is done with a flat stone and water; pounded Yorkshire paving-stone makes good grit. It is then rubbed smooth with wet sand in a similar manner. Lastly, the actual polishing is done with putty-powder, which is applied on thick felt stretched on a block of wood, and, of course, wetted. All the materials are sold by marble merchants. A little salt of sorrel used with the putty-powder brings the polish more quickly; but if the marble is black or coloured, this must be used with caution,—M. M.

**Writing-Desk.**—Cab.—Taking it for granted that the desk you require is of the form shown in Fig. 1, I will describe it. Your suggested sizes, 15 in. by 10 in. by 6 in., would answer, making the front, say, 5 in. deep; four ¼ in. boards for the sides, one ¾ in. for flap, and one for top back piece; a 1 in. bottom board, and three pieces for top gallery, besides two hardwood rails—this is the amount of wood required. Dovetail the sides together (as per instructions in back numbers), having previously shaped two or three tenons on their bottom edges; and to their tops, at the back, dowel the narrow top board, which is supposed to have been hollowed out for the reception of two ink-pots and pens. All tenons should be ½ in. deep, those at the sides fitting into ½ in. deep mortises in the bottom board, and those on the front and back lodging in clear mortises. Shape the under-side of the bottom board, at back and front, as in Fig. 2,

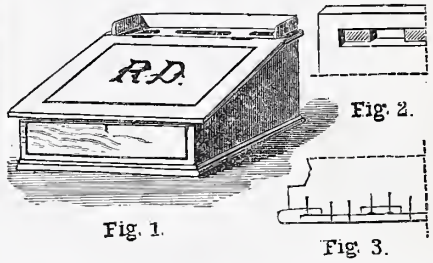


Fig. 2.

Fig. 1.

Fig. 3.

**Writing-Desk. Fig. 1.—Desk. Fig. 2.—Under side of Bottom Board (one corner). Fig. 3.—Elevation, showing Front Board tenoned to Bottom Board and secured by means of Rail.**

for ½ in. deep, in a line with the clear mortises, and insert a ½ in. hardwood rail. Thus, when the back and front sides are joined to the bottom board, their tenons will contact with the ½ in. rail, and by screwing the latter from underneath, and the bottom board to the upper boards, as shown in Fig. 3, a strong job may be made. You will see that by this arrangement a half-inch firmer hold is obtained by the screws used in connection with the bottom and upper boards than would otherwise be the case. You can dispense with these rails if you wish, merely screwing the bottom board to adjacent parts without their intervention. Stringing is done by the strings being glued into straight or curved grooves cut for the purpose in the solid wood, being pressed by the tool handle meanwhile. For the moment, I cannot say where you may obtain a catalogue containing prices of stringing; but should I eventually hear I will let you know.—J. S.

**Stove Trivets, etc.**—J. W. (*Swindon*).—To comply with your request for illustrations and designs for meat cranes, stove trivets, and flat-iron stands, I should require (to give anything of an assortment) about two pages of "Shop," which I am quite certain I should not get. Why not go to the nearest ironmonger, and ask him to show you the pattern books of the Carron Co., Stevens, McDowell and Co., and the General Ironfoundry Co.? and in them you would find a good assortment to select your patterns from. When will correspondents learn that it is impossible to give replies in "next issue?"—R. A.

**Violin—Lantern.**—H. McM. (*Bootle*).—You will find articles on the Triunial Optical Lantern in Nos. 83, 87, 91, 96, and 100 of Work; and papers on Violin Making in Nos. 105, 110, 114, and 118.

**An Invalid's Folding Adjustable Reading Stand.**—INVALID.—It is a curious fact that, upon receipt of your query for an invalid's reading stand, I was being compelled to indulge in the indolence of lying a-bed, where I had been shifting uneasily for several days, as the consequence of a slight accident I had met with. Strangely enough, I had been trying to discover how I could accelerate my professional labours by the aid of a piece of furniture; for the accident did not debar me from using my hands and arms. I had not quite designed one satisfactorily to myself when your letter was handed to me. Being in a position to sympathise with other invalids, I could the better comprehend their requirements; and I hope that the present result of my scheming will be of assistance to you. It is of very little use for me to give sizes, as in this case, more so than in many others, they are a matter of individual necessity. This article is intended to stand upon the bed, a foot being on each side of the invalid. Commence the construction by having a stout rail, the length of which will cover the distance across the invalid's body (bed-clothes included), and also allow a few inches extra at each

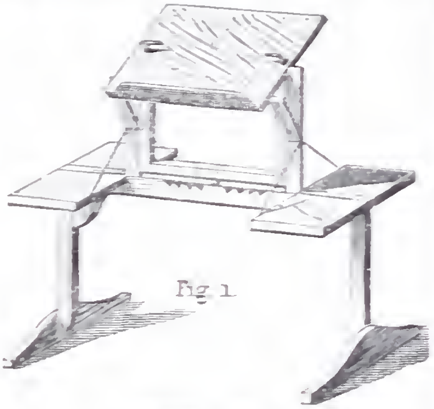

Fig. 1.

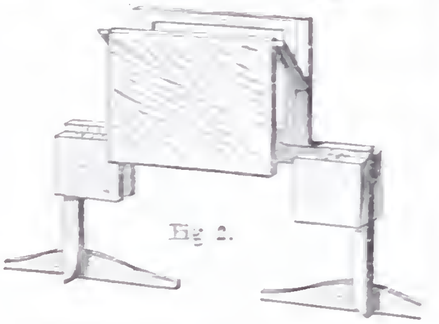

Fig. 2.

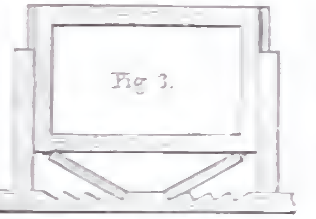

Fig. 3.

Fig. 4.

An Invalid's Folding Adjustable Reading Stand. Fig. 1.—Stand unfolded. Fig. 2.—Stand folded. Fig. 3.—Adjustable Frame for Stand. Fig. 4.—Section—A, Uprights; B, Adjustable Frame.

side. To the top of this rail should be joined two others, the distance between them being the same as the length of the desk-board. At each end of the long rail, underneath, will be joined an upright, to the bottom end of which will be hinged a long foot in such a manner that it can be adjusted as in Fig. 1, or folded, as in Fig. 2. To the two uprights should be joined, diagonally, two supports, between which the desk-board will be pivoted. Between the uprights should run a frame, as in Fig. 3, to the bottom edge of which may be hinged a pair of short rails to fit into notches in the long rail. The outside end edges of this frame should be tongued, and the inner edges of the fixed uprights grooved, of course, previous to joining together. The frame can then be easily raised, and the desk-board kept at any required angle, by permitting the short rails to fall into the notches. Fig. 4 shows section of frame and uprights. Now I have added something which you did not ask for, but which I consider, from my own bed experience, will be useful to you—viz., the shelves. A pair of small boards should be hinged to each end of the long rail. To save a lot of labour in placing supports for these, I should advise the use of a strong loop, each end of the latter being fastened to one of the shelves. If a nail or stout pin is driven into the thickness of each top upright, the string can fit over it, and thus support the shelves. It should not have a very large head; otherwise, when the loop is slipped over it, the shelves will be on the slant, instead of horizontal. Thickness for wood, you must decide. For strength, here and there fix a little bracket. You will require a narrow strip of wood to support the book, and also hooks to keep the leaves down. These hooks can be fixed on top, at the side, or at the bottom (for making, see p. 553, No. 35). You did not ask for a folding article, but I have designed it as such, for occasional convenience when not required. If, however, you would prefer it solid, you will have no difficulty in making it so. I think this article is to be preferred to one to stand by the bedside, for, by my late bed experience, I find that in bending in the bed it makes one's back and shoulders ache. I sincerely trust that but few of my readers will find it necessary to avail themselves of these suggestions.—J. S.

**Hydrogen Furnace.**—T. M. (*Liverpool*).—You could not make one of these so cheap or so satisfactorily as you could purchase one. Some very excellent furnaces are made by Thos. Fletcher & Co., Warrington. They will melt brass, copper, cast iron, and nickel, in quantities from 6 oz. to 28 lbs. The size of gas-pipes for the smallest quantity is ½ in., and range from that to 1½ in. With a chimney with a fairly good draught, they will melt copper; but for cast iron or nickel a blower is required. With a blower, they are calculated to melt a crucible of cast iron in seven minutes, steel in twelve minutes, and nickel in twenty-two minutes. If you send four stamps to the firm, they will send you their illustrated catalogue of melting furnaces, when you will see the various kinds they make. I should imagine it is one of these that is referred to in the article you name, but I have not seen it. If, after getting the catalogue, it is not what is referred to, if you send me the paper, I will try to give you some information respecting it. You will find drawings of the various kinds of furnaces in the catalogue, with prices and full particulars.—M.

**Electric Motors.**—H. C. (*Birmingham*).—Information respecting the Gassner dry battery was given in No. 53, p. 187, Vol. II.; and instructions on making and working accumulators were given in No. [illegible], p. [illegible], Vol. II.; and illustrated instructions on how to make a model electro-motor were given in No. 109, p. 71, Vol. III. of WORK. These three numbers can be forwarded to you by the publishers on receipt of 4½d. in stamps. For further information, consult back numbers.—G. E. B.

**Battery for Electric Light.**—W. B. (*Lewisham*).—The electric light battery described in "Shop," No. 131, p. [illegible], Vol. III. of WORK, in reply to F. G. (*Paddington*), cannot be re-charged with current from a dynamo. It must be re-charged by pouring away all the old spent solution, washing the plates and cells in water, and re-charging the cells with a fresh solution, made as directed in that reply. Four single-fluid batteries will maintain an electric light for about three hours; after which time the solution becomes spent or exhausted, and must be renewed.—G. E. B.

**Small Dynamo.**—LAMPLIGHTER.—I cannot advise you to attempt making the Brush dynamo. You will find those described in Nos. 88, 97, and 99 on pp. [illegible], [illegible], and [illegible], Vol. II. of WORK, much more simple in design, easier to construct, and quite as efficient for your purpose as a model Brush. Full illustrated instructions for making the Siemens, Gramme, Manchester, and Simplex dynamos are given in these numbers. No. 14 gauge copper wire is much too large for winding a model dynamo, and 65-volt 16-c.p. lamps unsuitable for such a small affair as yours. You will find full information in the articles on Model Electric Lights in WORK, Vol. II.—G. E. B.

**Universal Lathe.**—Mr. R. Prince's present address is [illegible] Stratford Road, Plaistow. It is on the Tilbury Line from Fenchurch Street Station. He is now working in his own little shop, and no longer in connection with Watt, Whitney & Co.—F. A. M.

**Horse Power to drive Dynamo.**—J. R. (*New Brompton*).—The following table will help you in determining the horse power needed to drive the Gramme dynamos:—

| Size. | Watts of Current. | C.P. | H.P. Required. |
|---|---|---|---|
| 1 | 125 | 30 | [illegible] to [illegible] |
| 2 | 250 | 60 | [illegible] to [illegible] |
| 3 | 500 | 120 | [illegible] to 1 |
| 4 | 1,600 | 475 | 2 |

Dynamos always run best when the horse power of the engine is in excess of the maximum power required to drive the machines.—G. E. B.

**Boiler Pump.**—PUMP.—I assume that the force pump is required to work in conjunction with a model engine, from the size of boiler given. You do not give the evaporation of water or other particulars from which to determine the capacity required in pump, but I think that illustrated below is about the size suitable. The figures are full size for a pump with a ½ in. diameter plunger, having 1 in. stroke. Fig. 1 is a plan of the top of pump and valve-box; Fig. 2, a vertical section of the same; and Fig. 3, a horizontal section taken on line 1—2. The cylindrical part of the plunger, A, is ½ in. diameter by 3 in. long, turned throughout; and it terminates at the top in a flat extension, having a hole-pin to receive a pin, by which the plunger is connected with a hand lever, or with a connecting rod from a crank or eccentric on an engine-shaft. The plunger should be made of iron or steel. The plunger is worked up and down, in a chamber about ¾ in. diameter, in a brass casting, B C, this chamber being on the side, B. The valve-box is formed on the side, C. It is not absolutely necessary to make the casting of brass, but for small work like this it is preferable. The general thickness of metal is ⅛ in., but where the pump-barrel and valve-box join, it is $\frac{1}{16}$ in. The top of the pump-barrel is bored out to fit the plunger, around which also fits a screw-gland, D, which screws down into a stuffing-box, O, filled with greased hemp packing, or packing of some other kind, to keep the plunger water-tight. The valve-box, C, communicates with the pump-barrel by a passage, L. The valve-box must be bored out to receive the seats of the inlet and outlet valves, K and J, which are shown as ball-valves, but may be of other form if desired. For special information on the subject of pump-valves, see WORK, Vol. I., p. 513 ("Pump Valves"). The balls sold for bicycle bearings may serve this purpose. The seats of the valves are turned so as to be a light driving fit to the valve-box. This will make them water-tight in the casing if the workmanship is good. The upper seat forms a stop for the inlet or suction valve, K, and a screw-plug, E, which closes the valve-box,

Fig. 1.

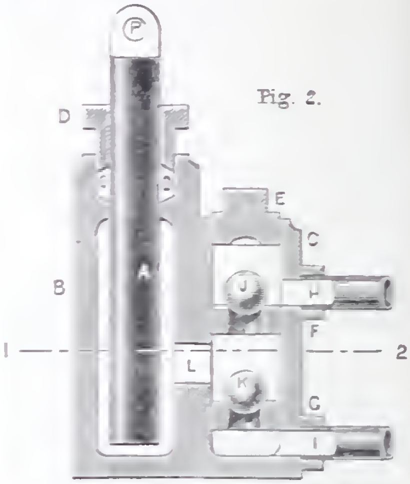

Fig. 2.

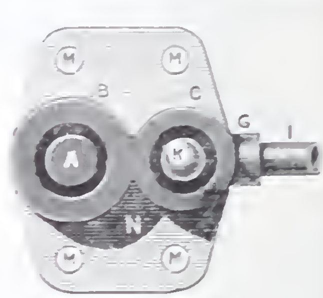

Fig. 3.

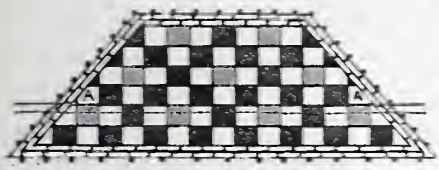
Boiler Pump and Parts.

forms also a stop to outlet valve, J. If there is any trouble to be anticipated about boring out the valve-box, it can be cast open at the bottom, and closed there by a screw-plug. The bottom seat may then be forced in from the bottom end, and the top seat from the top end of the valve-box, and a collar can be left between to secure their correct positions. I is a suction pipe and H an outlet pipe to the boiler. These pipes, about ¼ in. diameter, are screwed into sockets, G and C, in the positions shown. The bottom of the casting is extended on each side, as shown at N, to form a base-plate, with holes, M, for bolting or screwing it down to a frame. Instead of leaving a base-plate, side brackets may be cast on barrel, B, but this will depend upon the frame to which it is intended to fix the pump. At each up-stroke of the plunger a quantity of water is drawn through valve, K, and at each down-stroke a like quantity is forced through valve, J, and pipe, H, to the boiler. It will take about 200 strokes of this pump to deliver a pint of water into the boiler; so, from this *datum*, if you find the evaporation of boiler for a given speed of engine, you can calculate if the pump is sufficiently large for your boiler.—F. C.

**Jules Verne's Electric Light.**—F. M. (*Liverpool*).—Jules Verne's imagination has created a future for the electric light which seems unattainable,

and must, therefore, be regarded as pure fiction. No such lamp as that mentioned in his story, "A Journey into the Interior of the Earth," has yet been invented. It is true that luminous effects can be obtained from Geissler vacuum tubes when the secondary current from a Rhumkorff induction coil is sent through them: but these effects cannot be said to equal an electric light from incandescent lamps; nor would the light from a Geissler tube lamp be sufficient to guide an explorer's footsteps along subterraneous passages. I am not aware that such a lamp has been used for a photographer's dark room. An apparatus suitable to this purpose was described and illustrated in No. 89, p. 502, Vol. II. of WORK.—G. E. B.

**Lead Glass Work.**—S. I. W. (*Paddington*).—Below, you will find a sketch, showing about the shape, I presume, you would want one side of the top of your fern-case to be. You will find that, by the time you have bought the materials, etc., necessary to do a job of this kind, it will be a very expensive fern-case; but if expense is not so much an object as the pleasure of doing the whole thing yourself, you will accomplish what you wish with care and a little patience. I will now try to explain, by as simple a way as possible, how you can do it. First, set out on a piece of paper the exact size and shape you want: then decide and mark out the design and colours you would like. In buying your glass and leads, I should advise you to allow somewhat lavishly for waste, breakages, etc. Next, stretch your design (which, we will presume, is as the sketch below) flat on a board or bench: and, under the row of glass marked A A, lay a length of lead, opening out the grooves with a piece of hard wood, shaped to the form that suggests itself to you as being most suitable, to allow the glass to be inserted without any trouble. See that this lead is perfectly straight, and keep it in its place by a straight-edge lightly fastened below, as shown by dotted line, and some 1½ in. panel pins, driven lightly into the board or bench above, so as to keep the length of lead firmly in its position, shown by the drawing, under it. Now cut your first square of glass above this, beginning from the left-hand end, and fix it with pins driven lightly in above and on the left-hand side; next cut off a short length of



Lead Glass Work Pattern.

lead, and fit it up to the right-hand side of glass, making it sufficiently short to allow of the piece of lead coming on the top of this row to clip the glass: then follow with another piece of glass and lead, and so on to the end, drawing out very carefully any pins that may be in the way, and that were used to keep the first piece of lead in its place. Keep this row in its place by pins driven lightly on the right-hand side of last square; but draw out any that you may have put on the top of this row, and lay the next length of lead along and proceed in the same manner until the top half of the centre is complete. If you now carefully take up the straight-edge from under row A A, you can work downwards, and finish the bottom half, securing the whole with pins, as described. Next cut and fit in the corner pieces up the sides, and cut the long pieces of lead to their right length (which, by the way, should have been cut as you went along). You can now proceed with the border in the same manner, taking one side at the time: and when it is ready for soldering, it will be held together by pins all round it, as shown in sketch. Do not be afraid of putting in sufficient pins. If you now put a dot of solder over each joint, taking care that the heat of your iron does not crack the glass, you can then draw out the pins, and turn it over very carefully and solder the other side. The best iron, etc., for this I have already explained on p. 92, Vol. II.—E. D.

**Cutting Cone Patterns.**—TINNY.—My next article will deal with this subject. It is too long to properly explain in the limited space of "Shop."—R. A.

**Lantern Carrier.**—F. R. (*Gosport*) asks which is the best lantern carrier, and wants a dissolving effect with a single lantern. It is impossible to get the same effects with one lantern that can be got with two or more. By the carrier of which I give a description an instantaneous change of slides can be procured. Fig. 2 gives the carrier frame, A, in perspective, and B perpendicular section. At the lower part a piece is taken out as at *a a*—the width of the front—and sets as a saddle; the spring front pressing against it will keep it perfectly firm. Fig. 1 is the carrier proper; A gives it in perspective and B in plan. None of the Figs. are drawn to scale, and are purposely exaggerated in some points for the sake of greater clearness: but as dimensions are given, no error can be made. It will be easily understood that Fig. 1 slides in Fig. 2. At *a a* in Fig. 1 are screws which are used for the purpose of correct registration or bringing the picture in the centre. The slide is dropped in the groove from the top, when the carrier is flashed across and the slide last exhibited is removed, and a new one substituted. The carrier is now driven in the opposite direction. The one from which I have taken the copy is a home-made one: it is easily constructed, and quite as efficient as an expensive one from a dealer. I think the drawings are so plain that no further description is needed—except to say that

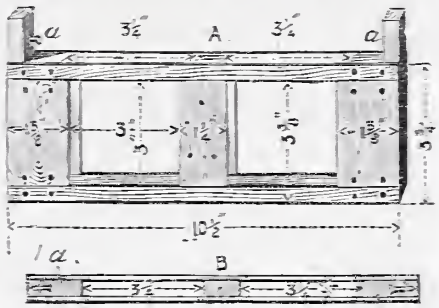


Fig. 1.

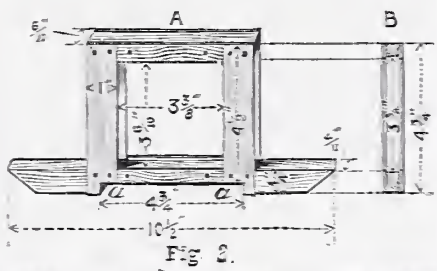

Fig. 2.

Lantern Carrier. Fig. 1.—Flash Carrier for Single Lantern. Fig. 2.—Guide Frame for Carrier: A and B, Plan and Section.

the proper width of the saddle-piece marked *a a*, in Fig. 2, must be determined by the width of the stage of the lantern; the one before me is 4⅛ in.—O. B.

**Bookshelves.**—QUARTO.—Your desire to fill a recess with bookshelves, enclosed by glass doors at the lower portion, without undertaking the labour of making a complete bookcase, is one the answer to which should commend itself to many other readers. So far as individual shelves are concerned, each might loosely lodge upon supports (A, Fig. 1), the latter being screwed to the wall as shown. If the wall is of such a nature that screws directly contacting with it are of little use, drive stout dowels, an inch or so long, into it under the end of each shelf; the object of the dowels being to accommodate the screws, thus permitting due tenacity. It is in no way compulsory to have either side or back board to the enclosed portion, as the doors can be hinged to narrow boards, which are

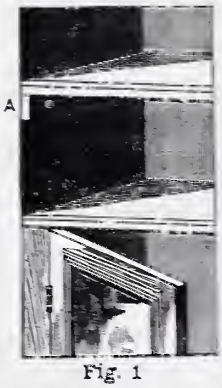

Fig. 1

Fig. 2.

Fig. 3.

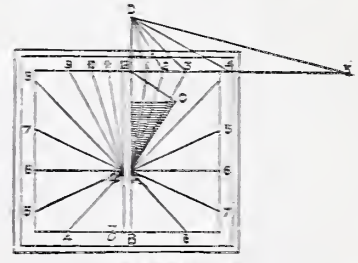
Bookshelves. Fig. 1.—End of Shelves and Top of Door. Fig. 2.—Corner of Enclosed Shelves. Fig. 3.—Pediment and Bracket for Shelves.

screwed or joined vertically between the board immediately above them, and one screwed to or near the floor. These uprights should also be screwed to any intervening shelves, the latter having their adjacent corners shaped as in Fig. 2, in order to permit this to be done. The back numbers of WORK will give you many designs of pediments and brackets suitable for adoption above and below your shelves; but perhaps those shown in Fig. 3 will assist you. The nature of the wood most suitable for you to use depends upon the appearance of your surrounding furniture, your taste, skill, and banking account. Either oak, walnut, or mahogany, pitch pine, deal, or, in fact, any wood, will equally suffice.—J. S.

**Materials for Coils.**—COMMUTATOR.—It must have been several years since you experienced such indifferent treatment at the hands of the dealer in odds and ends, as the paper you mention has ceased to exist as a separate publication. I have no cause of complaint against the person mentioned by you. The building is crammed from floor to roof with a large assortment of useful oddments, which should be seen and valued before purchase.—G. E. B.

**Accumulators.**—H. M. (*Keighley*).—Accumulators have been mentioned in "Shop" on pp. 477, 541, 749, 829, Vol. I.; on pp. 44, 206, 245, 266, 307, 622, Vol. II.; and on pp. 136, 172, 204, 285, 443, 475, Vol. III. of WORK. An illustrated article, showing how accumulators are made, appeared on p. 740, Vol. II. of WORK. The articles on Model Electric Lights were published in Nos. 76, 82, 89, 92, 94, 97, 99, 101, and 104, all in Vol. II. All back numbers and indexes are in print.—G. E. B.

**The Horizontal Dial.**—J. M. (*Aberdeen*) finds a difficulty in setting out a dial satisfactorily by the method given in WORK. It is possible that he may not have worked out the rule correctly, or fixed his dial with sufficient care. Another and perhaps simpler (though less compact) method for finding the hour-lines is, however, given below, with which, it is hoped, he may have better success. His opinion that the same hour-lines ought to serve for any place, irrespective of latitude, is not tenable: why it is not, he will see if he consults any work in which the principles of dialling are explained, as they are in most encyclopædias. *For setting out an horizontal dial for any proposed latitude*, draw the line 12 A B as the meridian or 12 o'clock line: parallel to which draw a second line (12 *a b*), at such a distance as will give a proper thickness for the gnomon. At right angles to these draw 6 *a*, A 6, for the 6 o'clock line: make the angle 12 A C equal to the latitude of the place, and from 12 let fall the perpendicular, 12 C, upon A C. Make 12 D upon A 12 prolonged, equal to 12 C. From D draw lines, D 1, D 2, D 3, etc. (to terminate in the line 12—5, perpendicular to 12 A), and to make angles, 12 D 1,



Horizontal Dial.

12 D 2, 12 D 3, etc., equal to 15°, 30°, 45°, etc. Then from the centre, A, draw A 1, A 2, A 3, A 4, and A 5 for the hour-lines of 1, 2, 3, 4, and 5 in the afternoon. Take on the other side of the meridian or substylar line, 12—11, 12—10, 12—9, etc., respectively equal to 12—1, 12—2, 12—3, etc., and from *a* draw the lines *a* 7, *a* 8, *a* 9, etc. All the hour-lines from 6 in the morning to 6 in the evening are LOW drawn, and it only remains to produce the afternoon lines, 4 A and 5 A, to give the morning lines, *a* 4 and *a* 5, and the morning lines, 7 *a* and 8 *a*, to give the evening lines, A 7 and A 8. The thickness of the gnomon has already been determined: the elevation of its style will be that of the angle 12 A C (equal to the angle of the latitude). It will be placed perpendicularly to the plane, on the space left for it with its angle, A, at *a* A, and its substyle extending towards 12.—A. Y.

**Intensity Coils.**—A. J. L. (*Gloucester*).—All instruments in which there are two coils of wire—a primary coil through which the exciting current passes, over-wound with another coil of wire in which an induced current of electricity is formed—are "induction coils." The name "intensity coils" is given to those which develop a high tension current in the secondary wire. "Medical coils" are induction coils constructed specially for medical and surgical purposes in the relief and cure of disease. The tension of the current from these is not so high as that from an intensity coil. By "ordinary coils" is meant the instruments made for and sold by opticians and dealers in electrical sundries, and advertised in the papers at low prices. These are nearly all imported from France. The ordinary coils mentioned by Dyer are the ordinary shocking coils furnished with a regulating core or a sheath to the core, to lessen or increase the inductive effects of the current. The various kinds of coils met with are all described in "Induction Coils," published by Messrs. Whittaker & Co. The principles of coil construction are given in a series of articles now in the Editor's hands, and I shall be always pleased to give you instructions in "Shop" on how to make spark coils and their accessories.—G. E. B.

**Winding Manchester Dynamo.**—W. D. (*Belfast*).—This correspondent sends me a tracing of a Manchester dynamo of the following dimensions, and asks: "About what quantity of wire will be required to wind it to give a current of three ampères at a pressure of 45 volts?" The dimensions are: yokes, 2 in. in width, 10 in. in length, ¾ in. in thickness; cores, 8½ in. in length between flanges; body, 1¼ in.

in diameter; flanges, 3 in. in diameter; armature, built of laminated Pacinotti punchings, 3 in. in diameter and 2 in. in depth. I cannot see any flaw in your excellent tracing, but think you will not be wise in reducing the thickness of the yoke from ⅝ in. to ½ in., as the heavier yoke will be an advantage in securing a steadier magnetic field. If the cores are of well-annealed cast iron, they will do equally as well as if made of wrought iron; but thinner flanges of wrought iron would be advantageous in yielding you more wire space. If you can manage to get 1½ lbs. of silk-covered No. 20 copper wire on the armature, and 6 lbs. of No. 22 on the cores, and connect the wires in shunt, you may get the current you require by driving the machine at a speed of 2,500 revolutions per minute. To get this result, the wires must be very closely and neatly wound.—G. E. B.

**Electric Lamps.**—G. W. (*Chelsea*).—I reply to your questions in order as they appear in your letter: (1) An electric lamp of 5 volts and 5-c.p. will take a current of 3 amperes, and this is a rate too rapid for a battery; 8-volt lamps are preferable. (2) All lamps, from 2½-c.p. to 20-c.p., are retailed by Mr. Bottone, Wallington. (3) A chromic acid or bichromate battery of four cells, each having a capacity of half a gallon, will supply current to an 8-volt lamp for from five to six nights with one charge of solution, if only used for three hours each night. If you only want a small night-light to see the time by night, and so on, see my reply on this subject to FRISKY, on page 683. (4) When using the current from a primary battery, such as that mentioned above, it is not necessary to employ a dynamo; but if you employ the portable secondary batteries supplied by Messrs. Cathcart, Peto and Radford, Hatton Garden, E.C., a dynamo will be needed to re-charge the cells when they are exhausted.—G. E. B.

**Marine Boiler.**—G. A. S. M. (*Birmingham*).—It is difficult to answer such a question without knowing more about your requirements. Do you want a regular marine boiler with internal tubes and smoke-box, for coal or charcoal, or do you want an externally fired one heated with spirit lamp, or a vertical one heated with coal or lamp? If you will give me an idea of your wants I will send a dimensioned sketch to suit you.—J.

**Common Sealing-Wax.**—A. W. (*Caterham Valley*).—A cheap strong wax may be made with powdered resin, 6 oz., and red lead, 4 oz., carefully melted over a slow fire. The *quality* of this may be improved (if cost is not objected to) by the addition of shellac up to 2 oz., and the *colour* by vermilion to a like weight. For sealing bottles, a sufficient wax may be made with two-thirds resin and one-third beeswax, coloured with a little venetian red.—M. M.

**Phosphor-Bronze.**—A. X. E. (*Nottingham*).—This is not really an alloy with a definite quantity of phosphorus, but a bronze which has been subjected to peculiar treatment. Bronze usually contains a quantity of cuprous oxide, which has been formed by the oxidation of some of the copper during fusion, and the presence of this oxide reduces the strength of the alloy. By adding phosphorus, the cuprous oxide is reduced to metallic copper, and a pure bronze of great strength and resistance is obtained. If the quantity of phosphorus added be the exact amount required to completely reduce the cuprous oxide, no phosphorus will be found in the resulting bronze; but, all the same, it will be still called a phosphor-bronze. Thus it is not a special alloy, but all bronzes can be converted into it. The phosphorus is added in the form of copper phosphide or tin phosphide, or some of each. Copper phosphide is made by heating a mixture of four parts superphosphate of lime, two parts granulated copper, and one part fine pulverised coal in a crucible at a moderate temperature. The melted copper phosphide, containing 14 per cent. of phosphorus, separates out at the bottom of the crucible, and should be quite black. Tin phosphide is made by placing a bar of zinc in an aqueous solution of tin chloride. The deposited tin is collected and put moist into a crucible, on the bottom of which are placed sticks of phosphorus. The tin is tightly pressed into the crucible, which is then gently heated till flames of burning phosphorus no longer issue from the crucible. The resulting tin phosphide is a coarsely crystalline mass of a tin-white colour. To convert ordinary bronze into phosphor-bronze, the alloy is melted, and small pieces of copper phosphide and tin phosphide are gradually added. The quantity added depends on the purpose for which the phosphor-bronze is required. Ordinary phosphor-bronze contains 2 per cent. or 2½ per cent. of phosphorus, and the best 3 per cent. or 4 per cent., although there is very little in the following analyses:—

| | | | |
|---|---|---|---|
| Copper | 90·34 | .. | 90·86 |
| Tin | 8·90 | .. | 8·56 |
| Phosphorus | 0·76 | .. | 0·20 |
| | 100·00 | | 99·62 |

A bronze containing 7 per cent. to 10 per cent. of tin gives a phosphor-bronze of greatest hardness, and suitable for bearings, etc.—F. B. C.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Steel Springs.**—WING writes:—"Can any reader of WORK inform me where I could procure a supply of steel springs, similar to those used for American clocks, about ⅜ in. wide, but in lengths of 22 in., and coiled to a diameter of 3 in?"

**Mounting Old Engraving.**—F. E. D. (*Bridgend*) writes:—"Will some kind reader of WORK give me a little instruction in the following? I have an old and, I think, valuable engraving, which is pasted on an old newspaper, and has been folded so many times that it is nearly in four pieces. Can someone tell me the proper way to mount on canvas stretcher previous to framing?"

**Early Riser's Friend.**—WILL writes:—"Can any reader who has made that Early Riser's Friend, described on pp. 423-425 of No. 131, Vol. III. of WORK, tell me through 'Shop' how much brass and zinc I should require to make same, where I could procure them, and at what price?"

**Photography versus Painting.**—A. B. (*Glasgow*) writes:—"Could any reader of WORK oblige me with the best method of photographing from an oil painting, if there is any special preparation put on the painting, or any special lens in the camera? I have had this tried with several first-class cameras by men experienced in copying photos, both landscape and portraits. They have always failed at the paintings, and have spent largely both in time and money in experimenting. We all think it rather strange, as the picture is quite distinct on ground glass before dark slide is put in, and the exposure has been tried at all stages; but still there was something wrong, so I am anxious for the information."

**Quick Drying Medium for Oil Colours.**—JUNIUS writes:—"Can any reader inform me as to the medium used by rapid painters (known as lightning artists) which causes the colours to dry on the canvas in less than an hour? I want a similar process for some work I have in hand to be executed on card for novelties, etc. Also what ought I to use for priming the card, which is straw-board, to prevent colours from sinking?"

**Dexter Fret Machine.**—E. W. (*Cupar, Fife*) will thank any reader for the address of the maker of this machine, or of a *depôt* where parts may be bought.

**Telephone.**—A. J. (*Lhanbryde*) writes:—"Could any reader kindly inform me where I could get directions, with an accompanying sketch of a Pulsion Telephone, whereby I could construct an instrument of that kind?"

**Roasting-Jack.**—NEWSTEAD writes:—"Will any reader kindly inform me (1) How to remove the gold from some gold blocking on leather? I want it to appear as only blind blocking. (2) How to make an inexpensive roasting-jack to work automatically, but without clock-work arrangement?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Glass Blowing.**—C. G. M. (*Penistone*) writes, in answer to SPES MEA (see p. 542, No. 138):—"By blowing glass on a small scale, I presume you mean, making such things as ignition-tubes, bulbs, T-pieces, etc., out of glass tube. This you can do with a blowpipe, but it requires perseverance."

**Water Colours.**—CHROMA writes, in reply to J. P. (*Belfast*) (see p. 574, No. 140):—"The pigments should be ground on a glass slab with a glass muller or flat-bottomed bottle, and mixed towards the end of that process with the medium; in this case a solution of gum senegal in distilled water—proportion, 1 oz. of gum ground to powder, carefully added to two fluid ounces of hot distilled water, and stirred and filtered. This should be kept in a large-necked bottle, covered, but not corked. Its keeping quality is improved by the addition of a lump of camphor. In the process of mixing with the pigment, a very little glycerine is incorporated, and it is this which keeps the colour moist. Sometimes honey is used for the latter purpose, and was invariably so. Of course, different colours require different proportions of medium, but these can only be ascertained by practical experience or experiment; but roughly speaking, the less the medium and the more the pigment the better, but always pure distilled water."

**Book on Locks.**—W. H. (*Edinburgh*) writes, in reply to J. G. (*Bloomsbury*) (see p. 478, No. 134):—"There is a book on the subject of locks, etc., in 'Weale's Series,' published by Lockwood, late Weale; the price is about 2s. 6d."

**Ivory Tablets.**—LIFEBOAT writes, in reply to SEA GULL (see p. 574, No. 140):—"Try the Endolithic Ivory Company, Limited, 61½, Fore Street, London, E.C. They make a speciality of this kind of thing; at any rate, they are largely patronised by organ and harmonium manufacturers for draw knobs."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—J. A. (*Halifax*); E. & S. (*Blackburn*); PROFESSIONAL; R. L. G. (*South Shields*); S. W. (*South Darenth*); J. A. (*Parsonstown*); W. B. MCG. (*Dumfries*); C. L. (*Beverley*); IRON FRAME; A. D. (*Sheffield*); J. W. B. (*Birmingham*); W. L. *** Advertisements should reach the Office fourteen days in advance of the date of issue.

## *SALE AND EXCHANGE.*

**Victor** Cycle Co., Grimsby, sell Mail-cart Wheels and Parts. [5 R

**Joiners' Tool List,** post free.—BOOTH BROTHERS, Dublin. [6 R

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath. 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repousse Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). [3 S

**½ h.-p. Horizontal Steam Engine,** as described in the pages of WORK by F. A. M. All the castings, forgings, and other materials required in the construction of these excellently designed Engines, may be had from H. MILNES, Ingleby Works, Bradford. Prices on application.

**The Buyers' Guide** to the best Books on Mechanical Subjects, with table of contents, price 6d. In cloth, 1s. 6d.—Published by BRITANNIA Co., Engineers, Colchester.

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of three thousand new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Machinery wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send two stamps for Register to Box 505, BRITANNIA TOOL FACTORY, Colchester. [7 R

**Try Bolton,** Burmantofts, Leeds, for Fretwork Materials. Lists free. [8 R

**For really good,** cheap, Mechanical, Electrical, Optical, Chemical, Photographic Apparatus and Models, consult CAPLATZI'S nine 2d. Catalogues.—Chenies Street, W.C. [10 R

**The Model Typewriter,** price 5s. Specimen of writing, one stamp.—WALTON, 9, Queen Anne Street, Stoke, Staffs. [1 S

**Paper Letters, Rubber Stamps, etc.**—Agents should apply for samples (free).—WILLCOX BROTHERS, 172, Blackfriars Road, London, S.E. [2 S

**Patterns** for general engineers, lathe, model makers, and electricians. Gas engines to order. Estimates given, stamp.—F. CHARLTON, 14, Starkey Street, Stockton-on-Tees. [4 S

# BEECHAM'S PILLS.

**WORTH A GUINEA A BOX.**

*A Wonderful Medicine for all Bilious & Nervous Disorders,*

SUCH AS

**Sick Headache, Constipation, Weak Stomach, Impaired Digestion, Disordered Liver, &c.**

BEECHAM'S PILLS have been before the public for half-a-century, and are to be found in every English-speaking country; they have by far the largest sale of any patent medicine in the world.

Prepared only, and sold Wholesale, by the Proprietor, THOMAS BEECHAM, St. Helens, Lancashire. Sold by all Druggists and Patent Medicine Dealers everywhere, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each. *Full directions with each box.*

COMFORT WARMTH & HEALTH IN WINTER

FOR **3/11**

We will supply you a very good Unshrinkable Flannel Shirt in pretty Greys and Fawns that will wear twice the length of time of any other shirt. Send size of neckband to **West Riding Flannel Co., Leeds.** Carriage Paid on two or more shirts. Write for patterns.

ESTABLISHED 1851.

**BIRKBECK BANK,**

Southampton Buildings, Chancery Lane, London.

THREE per CENT. INTEREST allowed on DEPOSITS, repayable on demand.

TWO per CENT. INTEREST on CURRENT ACCOUNTS calculated on the minimum monthly balances, when not drawn below £100.

STOCKS, SHARES, and ANNUITIES Purchased and Sold.

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH or A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY, as above.

The BIRKBECK ALMANACK, with full particulars, post free on application. FRANCIS RAVENSCROFT, Manager.

**GIVEN AWAY! YOUR NICKEL SILVER**

***PEN & PENCIL CASE,***

with your name in Rubber, complete, 7½d. Stamps, or for your Name or Monogram. Rubber Stamp for Marking Linen or Paper, enclose 3½d. stamps or postage, &c. Mention this paper, and address—

**Crystal Palace (John Bond's) Gold Medal Marking Ink Works, 75, Southgate Road London, N.** CAUTION: Original Patentee of the 6d. and 1s. Crystal Palace (John Bond's) Propelling Metallic Marking Ink Pencil

**THE DOUBLE-POINTED NAIL**

(*Durrans' Patent*).

**For Dowelling Joinery of all Kinds.**

INVALUABLE FOR CARPENTRY OF EVERY DESCRIPTION.

*Particularly Useful to Amateurs.*

Machine Steel cut Nails, ¾ in., 1 in., 1¼ in., 9d. per gross; 1½ in., 1s. per gross.

Sample boxes, assorted sizes, 6d.; by post, 8d.

These Nails are a perfect protection for fence tops and trellis work, preventing the ravages of trespassers and cats.

**Malleable Iron Fence Nails.**

Sizes, 2½ in., 2 in., 3 in., 4 in., 5 in., and 6 in., in 7 lb. bags, 3s. 6d.; per cwt., 55s.

***Durrans' Patent Nail Syndicate, Limited,***

43 and 44, Upper Baker Street, London, N.W.

**SILICO ENAMEL**

SAVES CLEANING & POLISHING

SILVER, PLATE, BRASS, STEEL, &c.

"SILICO" is a thin liquid enamel, finer than varnish, easily applied to all polished metals, dries in a few minutes, and forms a smooth invisible film that not only protects the metals from rust or tarnish, but preserves the brilliant appearance. It will not injure the richest metal, and can easily be removed if desired. As supplied to Government, Museums, etc.

Bottles with brush, **1s.**, from Cycle Depôts, Ironmongers, Stores, &c., or post free from

**SILICO ENAMEL CO.,**

97, HAMPSTEAD ROAD, LONDON, N.W.

(*See Notice in "Work," August 22, 1891.*)

No. 912, at 2d.

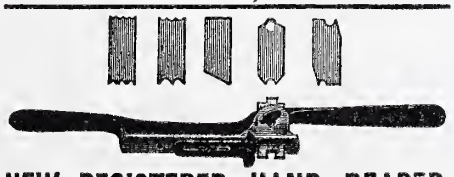
Volume V. of *The Amateur* commences with the January Part, 1892; now ready. Lists 43 and 44 of designs, wood, machines, tools, and cabinet fittings free. All goods greatly reduced in price.

**HENRY ZILLES & CO.,**

Publishers of "THE AMATEUR,"

*24 & 26, Wilson Street, Finsbury,*

LONDON, E.C.



**NEW REGISTERED HAND BEADER,**

With Six Irons, cutting Twelve different patterns in Reeds, Quirks, Rebates, Beader, Hollow Fancy Reeds. Length, 9½ in. Post free, 2s. 6d. Send for our 200-Page Catalogue, 700 Illustrations. By post, 6d.

**MOSELEY & SON, 323, High Holborn.**

MESSRS. CASSELL & COMPANY will publish in *Monthly Parts*, price *7d.*,

**The Story of Africa and its Explorers.**

By Dr. ROBERT BROWN, F.L.S., F.R.G.S., etc., assisted by eminent African travellers. Profusely Illustrated with Original Engravings.

***Part 1 ready Jan. 25.***

*** With Part 1 will be presented a Large Map of Africa (handsomely printed in Colours), showing the Routes of the Principal Explorers and European Possessions and Spheres of Influence.

*** *Prospectuses may be obtained at all Booksellers', or will be forwarded post free on application to*

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

**PAINTERS!! GRAINERS!! DECORATORS!!**

**The Art of Graining** is now complete, and contains 20 splendid plates. The finest example of graining ever published. Each plate is 18 x 13.

*Price in Parts, 36s. Bound, 42s.*

30 pages of Technical Instruction.

**Painted Wall Decoration.**

*2/6* The Christmas Number of the Journal of Decorative Art. *2/6*

A Perfect Manual of Design and Technical Instruction on

SURFACE DECORATION,

containing

10 LARGE SHEETS OF WORKING DESIGNS, BORDERS, DIAPERS, POWDERINGS, ETC. ETC.

(*Price 2s. 6d.; post free, 2s. 9d.*)

*For full particulars, see the November Number of* The Journal of Decorative Art. (7d.)

**W. G. SUTHERLAND,**

15, ST. ANN STREET, MANCHESTER.

**SIMPKIN, MARSHALL & CO., LTD.,**

317, STRAND, LONDON.

**KING'S COLLEGE.**

**ARCHITECTURE AND BUILDING CONSTRUCTION.**

Next Term commences 14th January.

The Day Lectures commence at 3 o'clock on Monday, 18th January; the Evening Lectures commence at 7 o'clock on Monday, 18th January; the Quantity Class commences at 6.30 o'clock on Friday, 15th January; the Constructional Drawing Class commences at 8 o'clock on Monday, 18th January; the Geometrical Drawing Class commences at 7 o'clock on Tuesday, 19th January; the Architectural Studio opens at 6 o'clock on Tuesday, 19th January.

Students nominated by the Worshipful Company of Carpenters pay HALF FEES.

For Prospectus, apply to the Secretary, at King's College, Strand, W.C.; or to Professor BANISTER FLETCHER, 29, New Bridge Street, Ludgate Circus, E.C.

*Post free on application.*

**Cassell's Classified Catalogue.**

**PICTURE FRAME MAKING.**

FOURTH EDITION. Enlarged and Revised.

**THE FRAME MAKER'S INSTRUCTION BOOK.**

*Diagrams, Designs, and Patterns.*

Instructions in Joining, Fitting, Mount Cutting, &c. Also Prices of Mouldings, and every requisite for the Trade. Post Free, **6 Stamps.**

**GEO. REES, 115, Strand** (Corner of Savoy St.);

***Moulding Dept.*, 41, 42, 43, Russell St., Covent Garden, London.**

***Just Published, price 3s. 6d.***

**THIS WORLD OF OURS,** a new book by H. O. ARNOLD-FORSTER, Author of "The Citizen Reader," &c., being Introductory Lessons to the Study of Geography. Fully Illustrated. Crown 8vo, 324 pages.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

CASSELL'S TIME TABLES.

# FRETWORK FOR AMATEURS

OF BOTH SEXES AND ALL AGES

The most Fascinating and Profitable of all Home Pastimes

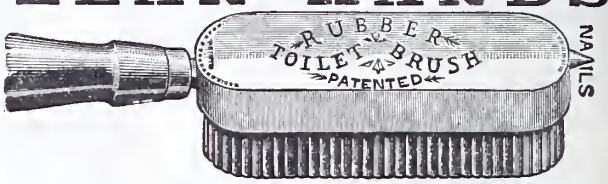
250,000 Fretwork Designs, 100,000 ft. Solid & 3-Ply Fretwood Veneers, etc., 1,000 gross Fretsaws, etc., always in Stock.

**To Beginners—A Complete Outfit, 2s. 6d., post free.** Comprising 12 in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient planed Fretwood, and full Instructions. 6 ft. assorted planed Fretwood, 2s. 6d.; 12 ft. ditto, 4s. 3d., post free. Book containing 12 sheets full-size Designs, 1s. Fretsaws, 1s. 4d. per gross.

New Catalogues of Machines, Designs, Wood, Tools, etc., with 60 pages and 600 Illustrations, and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design SENT GRATIS with each Catalogue; also a List of Designs. Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear. N.B.—All orders MUST be accompanied by remittance. Apply—**J. H. SKINNER & CO.,** Manufacturers of Fretwork Materials, W Department, **East Dereham, Norfolk.**

*Kindly mention this paper when ordering.*

# CLEAN HANDS!



*For Everyone, no matter what the Occupation.*

Nothing has ever been invented that will so thoroughly cleanse and whiten the hands as our **Rubber Brush.** Used with soap and water, it will remove all kinds of stains, **Ink, Tar, Iron Stains,** and **Paint,** yielding easily to it, without injuring the most delicate skin, as is done by using pumice stone, bristle brushes, &c.

Price 1s. Larger Size, price 2s.

We are also the makers of BAILEY'S CELEBRATED RUBBER BATH and FLESH BRUSHES, price *5s.* each; COMPLEXION BRUSHES, price *3s. 6d.* each; RUBBER TOOTH BRUSHES, price *10d.* and *1s.* each; and TEETHING RINGS, price *5d.* each.

*To be had from all Chemists and Dealers in Toilet Goods, or will be sent, post free, on receipt of price by the Manufacturers,*

DAVID MOSELEY & SONS, 14, Aldermanbury Avenue, London, E.C.
Ardwick, Manchester; and 57, Miller Street, Glasgow.

NEW VOLUME JUST COMMENCED.

*80 Pages, Monthly, price 6d.*

# THE QUIVER.

*FOR SUNDAY AND GENERAL READING.*

"There is no help for it. Without withdrawing one word written in praise of the other sixpenny magazines of this kind, we are bound to say that THE QUIVER, alike for quality and quantity, for variety of literature, and for charm of illustration, stands at the top of the poll."—*Methodist Times.*

"THE QUIVER is an amazing sixpennyworth; the illustrations are so good, and the style is so fresh and attractive, combining solid instruction with much that is entertaining and bright."—*The Rock.*

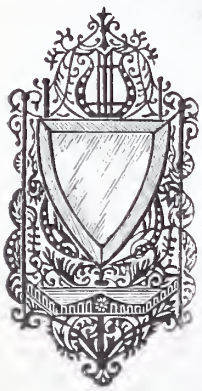
"THE QUIVER contains a rich variety of matter, religious and secular. It is unquestionably ahead of its contemporaries in its illustrations."—*Times.*

"THE QUIVER is best of all the magazines devoted to Sunday reading."—*Saturday Review.*

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London; and all Booksellers.*

# FRETWORK AND CARVING.

*Highest Award—GOLD MEDAL.*



MACHINES, DESIGNS, TOOLS, WOOD, MIRRORS, HINGES, AND VARNISH, &c.

Fretwork Outfits, 1s. 4d., 2s. 6d., 3s. 6d., and 5s. 6d. each.

*Sets of Twelve Best Carving Tools, with Boxwood Handles, 10s. free.*

All Materials and Tools supplied for Fretwork, Carving, Picture Framing, Brass, Leather, and Burnt Wood Work.

Our Catalogue, acknowledged the most complete, with 1,000 Illustrations, and all Instructions, free for six stamps.

**HARGER BROS., Settle, Yorks.**

**LEE'S ILLUSTRATED CATALOGUE OF SELECTED**

# AMERICAN TOOLS and MACHINERY.

Screw Cutting and other Lathes, Chucks, Slide-rests, Lathe Dogs, Polishing Lathes, Drilling Machines, Drills, Parallel and Instantaneous Grip Vices, Screw Stocks, Taps and Dies, Saws, Wrenches, &c., &c., specially selected from the best American Manufacturers, therefore of the very highest quality, and at low prices. *Send for Illustrated Catalogue, 150 Illustrations, price 6d., post free.*

MODEL STEAM ENGINES, and Complete Sets of Castings of same, of every description, from the smallest to powerful Engines.

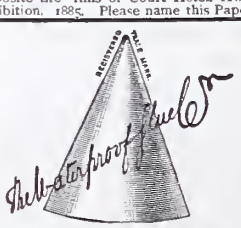
**LEE'S ILLUSTRATED CATALOGUE.**

New and Revised, Prices greatly Reduced. To Amateurs the most useful book extant, and largest and best Catalogue in the Trade. 64 pages, 110 Illustrations, price 6d., post free. Please state whether American Tool or Model Steam Engine Catalogue is required when ordering. ONLY ADDRESS— *76, 77, and 78a, HIGH HOLBORN, LONDON, W.C.*

Gateway entrance directly opposite the Inns of Court Hotel. Awarded Prize Medal International Inventions Exhibition, 1885. Please name this Paper when writing.

**FLUID**
WATER RESISTING
**GLUE**
(*Patent*)
PATENT TINS.

*Invaluable for all Out and Indoor Repairs.*



**FLUID**
WATER RESISTING
**GLUE**
(*Patent*)
PATENT TINS.

No Brush—No Boiling—Will securely join Wood, Glass, China, Metals, &c.

*By Post, 8d. and 1s. 3d. per tin. Through Ironmongers, Chemists, Chandlers, &c., 6d. and 1s. per tin.*

Manufactured only by THE WATERPROOF GLUE CO., 62, Dale St., LIVERPOOL.

PRINTED AND PUBLISHED BY CASSELL & COMPANY, LIMITED, LA BELLE SAUVAGE, LONDON, E.C.

## An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 148.] SATURDAY, JANUARY 16, 1892. [PRICE ONE PENNY.

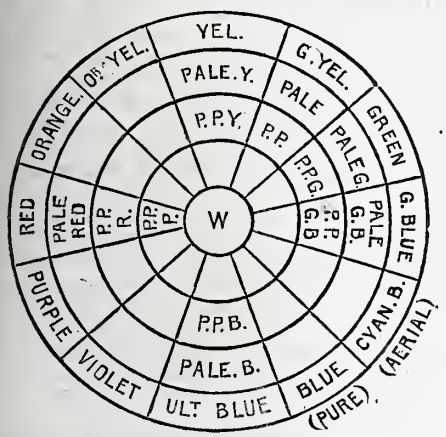

Fig. 1.—Contrasting Colours opposed in Sectors, with Corresponding Tints by addition of White. After O. N. Rood.

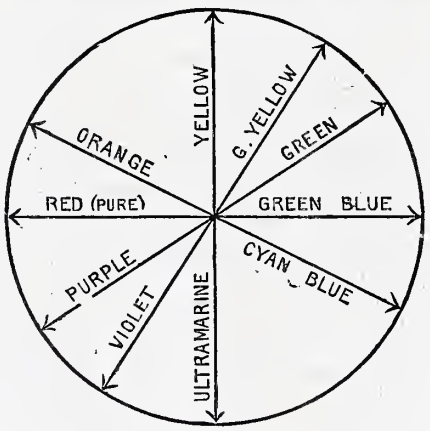

Fig. 2.—Pure Spectral Colours arranged in a Circle to show Exact Complementaries. After O. N. Rood.

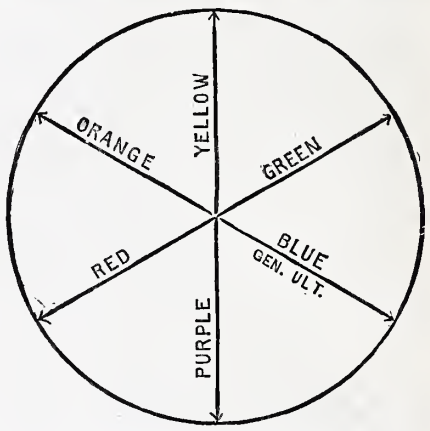

Fig. 3.—Complementary Colours of the Old Theory. After G. Field.

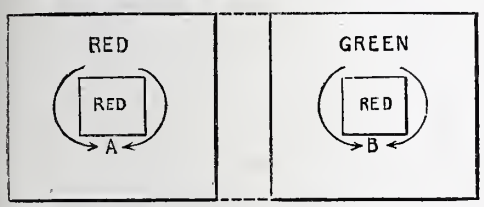

Fig. 4.—Pieces of Red and Green Paper with Red Squares placed thereon. Result—B appears brighter than A.

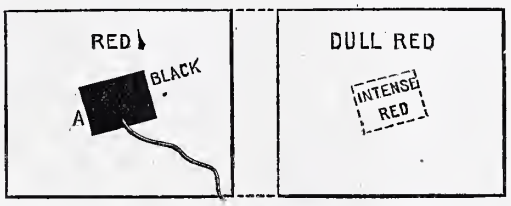

Fig. 5.—Red Paper with Black Disc. Gaze intently, draw A away, leaving Image of Brighter Red.

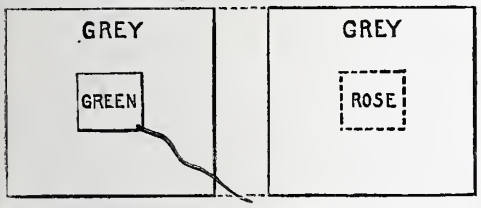

Fig. 6.—Grey Paper with Green Slip. Gaze intently, then remove, leaving Rose-tinted Image.

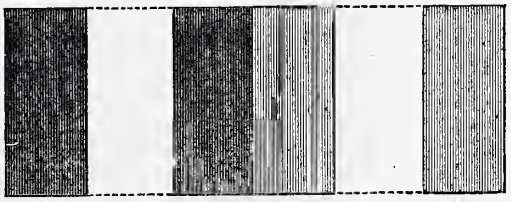

Fig. 7.—Forced Contrast of Shade. Two Tints of One Colour placed thus, the difference appears greater.

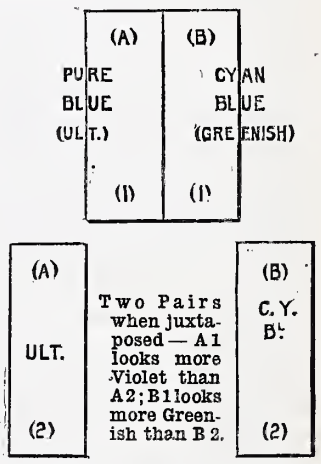

Fig. 8.—Forced Contrast of Hue or Colour Contrast.

*** Figs. 1, 2, 3, showing Complementaries, and Figs. 4—8 for Experiments with Contrast Effects, should be reproduced with properly Coloured Surfaces three or four times larger.

## COLOUR IN OUR HOMES.

BY FREDERICK PARSONS, F.S.Sc.

COLOUR—ITS PRACTICABILITY—ÆSTHETIC PROVINCE AND VALUE—SENTIMENT AND ITS EXPRESSION IN COLOUR—FOR DINING AND DRAWING ROOMS—HALL AND STAIRCASE—STUDY AND SLEEPING ROOMS—COLOUR CONTRASTS AND CONCLUSIONS.

"OF all God's gifts to the sight of man, colour is the holiest, the most divine, the most solemn."

Although a considerable period of time has elapsed since Ruskin sent forth into the world this remarkable sentence, its truth and importance are still almost unknown and unappreciated by the mass of workers. Notwithstanding the reproach that same prophet levelled against us, that as a nation we are insensible to the value of colour, has been of recent years to some extent removed, to the great majority of to-day my opening lines read more like the far-fetched outpourings of an eccentric art critic than as the simple statement of a beautiful fact. That which the art of music is through the sense of hearing—a source of pure enjoyment and elevation of the mind—so a bountiful Creator intended colour to fulfil a like mission through the medium of our vision. Were it not so, for what other reason could the fields be clothed with soothing hues of green, the ripened corn reflecting back, as it were, the glory of the golden orb of day? Why do not the ethereal vaults of illimitable space ever appear a dreary expanse of wintry grey? These and a thousand other like questions have one common answer. Their colour is to cheer and brighten the soul of man. The necessities of our present purpose, however, require that we forsake metaphysical consideration of colour for its more definite and ministering visual aspects. In this latter course we are at once confronted by various difficulties. Teaching colour without being able to appeal to the mind by the aid of samples is akin to attempting to learn a musical instrument upon a dummy keyboard. Worse, indeed, since Do. is the same on all pianos, whilst *my* "aërial blue," "old gold," or "terra cotta" may be considerably different, my reader, from *your* interpretation of these indefinite colour terms. Beyond this fact, successful application of colour demands a foundation of some practical and theoretical knowledge, and here we have but little space for considering either. Incompleteness must, therefore, characterise my paper; nevertheless, if it be the humble

means of arousing the interest of some readers to the dormant claims and pleasures of "colour in the home," to those, at least, this effort will not be unsuccessful.

*The practical utility of colour* is a consideration well worthy a few lines herein. An eminent scientific man and author of valuable works on colour, the late George Field, in answer to a query on the subject, says that colour is of *no use!* This is too sweeping an assertion for us to pass by unnoticed, for although, as he truly writes, the colours of flowers are not known to serve any real purpose, we must discriminate a little when dealing with nature's colour painting and colours applied by man. It would be worse than useless, however, to endeavour to argue this point by the aid of suppositionary deductions from a world without colour. The bare suggestion of a gloomy earth of monotone ranging but from ghastly white to a blackness "that may be felt," is depressive enough for all of us. The colours of ordinary oak-grained or marbled surfaces, the ever-durable range of "stone," "buff," "drab," and brown tones are, however, familiar to us owing to their *usefulness* more than to any considerations of beauty; whilst many of us would strongly object to an exclusive usurpation by the world's creative or purely material objects and forces of the term "useful." In its application to moulded form, as shown in a preceding paper, colour has very definite properties, and especially in the Gothic and Mauresque styles of architecture and decoration it is a form-creative power, giving results entirely beyond the effects of light and shade, or monotone.

It is for its *æsthetic value*, however, that colour must be chiefly studied and employed. As a medium for conveying the poetic sentiments of one mind to the understanding of others; as a pleasure-giving factor in this world of commercialism. This is the cause we are trying to plead. Every year finds musical powers and culture, the source of tonal harmonies, more general to all homes. The province of colour is equally as definite as music, and perhaps more widespread, for Nature gives us all lessons in colour, and evidently meant us to have pleasure therefrom.

*Sentiment* is without doubt the inward and intellectual force of outward, visible colour signs. The faculty of expressing poetic thought by the medium of colour and form does not come naturally to us all, any more than do the powers of poet and musician. Neither, from the same reason, are we alike all able to appreciate and interpret elaborately poetic or, as it is commonly termed, *harmonious* colour. Modern civilisation and scholastic training teach us to dislike harsh discords of sound and colour, but will not enable us, intuitively, to produce harmonious combinations. Even as a limited power of discrimination is common to all of us, so it must further be recognised that natural faculties or "gifts" of expressive power in either music, language, colour and form are but the happy privilege of a limited few. Study and perseverance can work wonders towards the acquiring of these powers, but it is seldom that the highest degree of excellence is reached without the co-operation of the natural, pre-existing faculties. Thus having unburdened one's mind so far as appeared necessary respecting colour "in the abstract," we may now consider it as a power of visual expression.

*Expressions* of colour is a term here used solely with respect to colour language conveyed to the brain through the medium of our vision. The sun's rays—the first cause of all colour—may be considered and analysed both from visual and chemical standpoints, the latter being only intimately concerned, for instance, with photographic and kindred processes. We will content ourselves by now broadly stating a few accepted scientific facts. (1) That white light is composed of all colours; (2) that all colour sensation or vision is caused by the stimulation of the optic nerve; (3) that light reaches the vision in infinitely small wave formations; (4) that the different colour sensations are owing to the various differences in length of these undulating waves; (5) that, with perfect vision, there exist certain colour nerves corresponding to certain colour wave-lengths; (6) that different coloured lights will in some cases produce by their union white light; (7) that coloured lights, and hence coloured surfaces—coloured light necessarily and naturally forming the basis of practical colour study—which so combine are known as complementary colours; (8) that complementary and contrasting colour combinations provide us with a scientific foundation for the principles and practice of *colour harmony*—foundation only! The successful superstructure must be the outcome of knowledge, experience, and faculty.

Having thus briefly set forth the source of colour sensations and the theoretical basis of colour harmony, so far as present considerations required of us, we will again take up the thread of our subject—colour expressions.

The "language of colour," if we may so term it, finds its elements in Nature; whilst the particular sentiments usually associated with particular colours in the ancient science and art of heraldry, and also in symbolism of colour, fully accord with our natural colour impressions. Let us consider the principal colours, commencing with *Yellow*, the nearest in position to white. Yellow immediately turns our thoughts to the source of all light, and—to quote Baron F. Portal—"the heat and brightness of the sun designate the love of God which animates the heart and the wisdom which enlightens the intellect." Heraldic distinctions further associate with it "gold," the richest and most brilliant metal; the glory of midsummer "July" and "noontide;" also "blitheness" and "force"—all of which are characterised by one vein of sentiment.

With *Red* colour we naturally associate fire and heat, or, in its milder sentiments, warmth and comfort. In ecclesiastical decoration red signifies the consuming, never-failing fire of Divine love; whilst heraldry classes with it the age of "manhood," the activity of "passion," and the virtue of "charity"—*i.e.*, love. *Blue* finds its corresponding sentiment in the expanse of the heavens speaking of illimitable space; the truths of immortality; the faith as of childhood; and in heraldry of justice, of the summer season and the element of air. The common association of blue with the cool sensation of water is owing to the sky colour being reflected in the latter; to the blue appearance of snow-clad mountain tops; and, particularly, by reason of blue being a strong and direct colour contrast to yellow and red, viz., light and heat, it follows that coolness and distance are the particular expression of all blue combinations. With *Green* we associate the cheering vegetation of spring-time. Pure green is much more scarce in Nature than we imagine. The coolness and soothing characteristics of Nature's varied green tones is due to a large admixture of cool, grey atmospheric hues. Green in heraldry is classed with "youth" and strength, but as in temper it is designated by the term *bilious*, we still get a suggestive rendering of its dangerous expression when used in a *pure* state. If for the moment we here accept the three colours, red, blue, and yellow, as being primary or source colours, and which by admixture produce every other colour, such being true *respecting pigments*, but totally *wrong in relation to colour* waves, or coloured light, it follows that their colour expression may be equally varied and combined. In addition to the foregoing, however, we must analyse the two extremes, or neutrals rather, of white and black. The sentiment of *white* is pre-eminently "purity," of the "unstained." It is associated with the "morning" of day, the "infancy" of existence; of the "beginning." In heraldry, again, its associates are the element, water; the whiteness of silver, and its floral type is the "lily." Lastly with *black*, as we all know and feel, the mind is stirred to the depressions of winter and night. Old age and decay in their natural order answer not to the colour sensations of childhood, youth, or manhood. The things of this perishable, material earth lose themselves in physical decay, and so, as with colour, the end of the course is neutrality. One point in its connection with the ancient heraldic art we must not overlook, namely, that black in connection with the virtues is consistently interpreted as "prudence."

Now for the practical value and service of the foregoing — its connection with "colour in our homes." In the first place, let us note that as white light contains all and mixes with all colour, so white bodies have the same province in using material colour, both being necessary in great proportion to the service of colour. Taking now the *drawing room* of present civilisation, what should be its colour expression? White ought to predominate either in mass or in combination as tints with other colours—and these colours? First yellow, then its contrast blue. Yellow to add richness and brilliancy, blue to relieve and enhance it—just as the "field" of blue sky in contrast to the sun. But why not pink or green sentiments, it may be asked? For these general reasons—that light, not heat, should predominate, that light and heat together are inconsistent with the sentiment of such a room, and, further, that true green is not only bilious of temper but almost fatal to mixed combinations. Next consider the *dining room*. Its modern purposes are chiefly displayed by artificial interior light, hence white plays but a humble part in its treatment. Red tones for comfort and warmth are most natural. Red also, although classed as a stationary colour, is safer in practice when toned down with black, or in positions naturally shaded. Try a mass of fiery red, then add an equal proportion of black and note the resulting sentiment, "prudent heat"—red toned with black. Again, add white to red, result—heat still too powerfully dominant. *Halls* and *staircases* are not used for living purposes, hence their colour expression may not be so arbitrarily stated. If well lighted by Nature we must restrain our hand in the positive sentiments generally; but if badly lighted, then we aim to give expression to brilliancy and cheer. In our own country, where dull and cheerless weather predominates, the warm and cheerful tones are the most successful. The *study* and *library* are open to much divergence

of colour treatment. Either of the positive colour sensations are in keeping with the use of the room; but expediency must be studied, and unless the natural light is very poor, white and yellow are "bad language." The book or the epistle is the mind's light and cheer; the surroundings, therefore, must not rival its attraction. In *sleeping apartments*, pure and simple, white must stand pre-eminent as correct expression. The pure slumber of childhood, hopeful hearts for greeting the possibility of each day, and the wished-for brightness and freshness of morning are thoughts at one with its use. Nevertheless, we wish not for either in the extremity of their force and agitation, and probably prefer the dominant white toned down with a little warmth (red), or the soft peace of truth and repose (blue); or, again, if our apartment is badly served with Nature's brilliance and strength, we may surround us with *blithe* yellow.

We have now discovered how our homes may be made pleasing *melodies* of colour—visual expression of our minds. But we have not learnt of the *harmonies*, the chords, so to express it, of poetic colouring. The little of this that can be taught by pen and ink is still far too much for this paper. The fringe of the subject we, however, must touch, in conjunction with the foregoing and this with respect to contrast. Good *contrasts* in *colour* are such opposing sensations as heighten and improve each other when juxtaposed; contrast is therefore an important feature in harmony, corresponding to the factor, *interval*, in music. If we have various sentiments of colour under one roof, we also must have satisfactory contrast between them. It has been before stated that in perfect vision there are colour nerves—nerves excited by distinct colour. If one's eyesight is minus its red colour nerves, colour blindness to red is the result; so with other colour. If we tire the red colour nerves by long-continued gazing at red, the remaining nerves which combine with red to convey to us perfectly balanced or "white" sensations have still their strength unimpaired. From this cause, when we glance rapidly from a spot of red upon a field of white to a surface of all white, the space corresponding to the former spot is tinged with the corresponding tint of the unexcited colour nerves. The simple diagrams shown on page 689 will provide experiments for the interested. The scientific aspect of colour contrast concerns us here in this much—that due allowance must be made for it in "home" colour schemes, otherwise we may be disappointed in the complete *ensemble*. For instance, colour a dining room red, of any intensity. Have the hall, or room approach, afterward coloured intense green-blue. The result will then be that the red appears doubly intense and brilliant after looking at the hall colour. Harsh or strong contrast is a matter irrespective of harmony, like a chord, *piano*, and then the same again, *forte*. We live in an age of temperance and moderation, therefore let our colour contrasts be consistent therewith; not autocratic and overbearing in sentiment, like the ancient Egyptian and Chinese colourings, nor depraved and sensuous like the Pompeian, but simple, temperate, and expressive.

For our diagrams on contrasts and complementaries we have borrowed from that invaluable little volume, "Modern Chromatics," by Ogden N. Rood. Although it may not happen that many of our readers will continue the search for colour enlightenment, which we have here endeavoured to initiate, by studying the modern works of Professors Rood and Church, we hope that these results will be found in each case—viz., a perception that untrained "taste" alone, in dealing with *colour*, is little more than an imprudent usurper of the province of study and experience; and further, that successful combinations and colour-studies require something more than a haphazard shuffle of the colour-cards or their accidental kaleidoscopic re-arrangement.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Setting Out—Halving—Dovetail Halving.

Although the two forms of joining wood already mentioned are of great importance, being so frequently used, halving and dovetail halving are of great use in many cases, especially where alterations and additional rails are to be placed in a piece of work already glued up. In such a case, mortise and tenon are out of the question. The setting out for halving is simple, but must be well done to obtain good results. A mortise gauge is not required, but a finely sharpened marking gauge. As halving, so called, need not be exactly what its name implies, the part cut away in each of the pieces may be modified as any special circumstances direct. The gauge is to be applied to the marked surfaces of the wood, cutting up to the lines when making the joint; in one case the front is cut away, and in the other the back. At exterior angles halving needs the assistance of glue or nails, etc., as, unlike dovetails or tenons, there is no retaining property in the joint itself. Nor is dovetail halving much better in this respect; but where halved or dovetail halved joints occur in other places—that is, at the end of one timber and somewhere between the ends of the other—there is a retaining power, and therefore the joint is stronger. I have seen frames for overmantels, all the joints halved and glued, and when slight inequalities of either pieces were removed, and the whole overlaid with ¼ in. walnut glued on, the rebates for glass being formed by the walnut being wider than the pieces composing the frame, a simple but strong construction results. Dovetail halving only differs from halving in the form of the tongue or end, which is cut with the reversed wedge shape which is common to dovetails; only one dovetail is, as a rule, required, and the best use of the joint is when two pieces are to be joined like the letter T. This joint also can be used for work in progress, without the unbuilding which a mortise and tenon would involve.

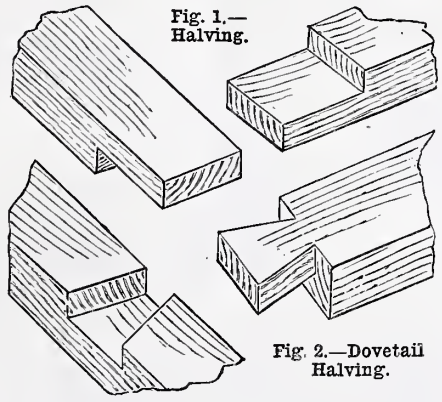

Fig. 1.—Halving.

Fig. 2.—Dovetail Halving.

It is not easy to separate the setting out of this joint from the work of doing it, because the dovetail is generally sawn by the aid of the eye and judgment of the worker, and the socket made afterwards, either by marking with the saw *in situ*, or with a fine scriber or a well-pointed pencil, on the piece of wood in which the socket is to be cut. It is best, however, to mark the intersection of each piece on the other, for such lines form part of the shoulder of the dovetail. When the pupil has mastered these joints he will be able to make a bench, and in so doing he will use each of those already mentioned. The legs will be united in pairs by mortise and tenon, while a continuous sideboard may with advantage be dovetailed at each corner. The cross pieces at the top of the legs may be halved or dovetailed, and the rails which support the top may with advantage be dovetailed or dovetail-halved into the sideboards.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

Toasting-Forks—Block for Formation of Four-Prong Forks—Three-Prong Forks—Machine for Twisting Fork Wires—Gridirons—Their Formation—Steak-Toasters—Gravy Pans, etc.—The Frames—The Hooks—Ladles—The Framework and Spring—Straightening Wires—Second Kind of Ladle—Framework, etc.

**Toasting-Forks.**—In the winter, when a blazing fire is exposed in full glare before us, and we can hear the horses' hoofs continually slipping over the icy roads outside, amidst the struggles of the unfortunate animals; when the hands and face are scorching hot, the eyes dried up, and the vision obliterated by the heat of the fire; and the toes feel cold and are covered with chilblains, while a cold shiver runs up the back now and again, travelling no one knows whither—then is the time when a slice of toast is welcomed, with a cup of tea.

Several of us, no doubt, can testify to the personal discomfort experienced when the operation of toasting is performed by means of an ordinary dinner fork. The fire *will* burn our fingers—and the toast in addition. The man who first invented toasting-forks truly deserves our gratitude. How he was accustomed to make them I cannot tell, but they are at present extensively made in the manner I am about to describe.

*Block for Formation of Four-Prong Forks.*—A wooden or metal block, with four holes drilled through its length (as represented in Fig. 158) is fixed in the vice. Two wires of the proper length are bent as in Fig. 156, their ends being level with each other. A twist is given to the top by means of a small rod (A in Fig. 159), making that part appear as in that diagram. Each of the four lengths is then passed through a hole in the block, as shown in Fig. 158. The rod A (Fig. 159) is inserted in the loop at the end and turned round and round, as in winding a clock. The wires are consequently regularly bent or twisted round each other. When they are twisted a certain distance they will be as shown in Fig. 164, the two outer ends at this point being bent outwards, as appears in Fig. 164, and the two inner ends in a similar manner. The outer ones are again bent as in Fig. 165, and the inner ones also again

as in Fig. 169. The final bending is accomplished by their being placed under a cylindrical object and the remainder of the fork bent upwards, appearing afterwards at the prong ends as in Fig. 168. A wire is then secured across the prongs for purposes of strength.

*Three-Prong Forks.*—Three-prong forks are very numerous, and can be made in a somewhat similar manner to the four-pronged articles just described. Instead of four there must in this case be three holes in the block (as in Fig. 160). And there will also be three wires of the same length as each other. One end of each wire will be bent as in Fig. 157, and all three passed over and under each other as there represented, in order to make a secure and strong job. All are, of course, pushed close together, my purpose for showing them open being to give a clear view of the manner in which they are interlaced. The wires are then placed through the holes in the block, and served in a similar way to the wires composing the four-pronged forks. The instructions given in reference to the latter will be equally applicable to those at present under consideration, with the exception that the middle wire is only bent once, and that as in the curve shown in Fig. 168.

These forks are made in a great variety of lengths. When a particular size is decided upon, a large amount of superfluous wire should be allowed to remain until the rest is twisted up, as during this latter operation, the four or three lengths of wire, as the case may be, will twist up into a much shorter length than they will originally be.

*Machine for Twisting Fork Wires.*—For the sake of expeditious manufacture an arrangement similar to that shown in the drawing could be utilised. A comparatively heavy block, such as, for instance, one made of iron, would have to be used in conjunction with it in this case. A reference to my article on "Twisting" must be made. It will there be seen that this simple contrivance corresponds in a great number of particulars to the one there shown, therefore, the remarks I make in relation to the one described in that paper can be appropriately applied where necessary to the one given herewith. The difference between the two can be seen. The arrangement fitted on the one at present requiring further description is intended to receive the loop of a toasting-fork in order that it may be turned, and thereby twist the wires, by being placed over the rod, B (Fig. 166), and the handle then revolved.

Fig. 166 shows the arrangement by itself. A is a hinged plate, shown alone partially in the same sketch. The rod, B, revolves in a socket at each end, and at the top end of it there will be a catch, as shown in Fig. 166. When about to place the fork loop on the rod, B, the latter is turned in order that the catches may be released, and the plate, A, is lifted. When the loop is upon B, all is again replaced as in Fig. 167.

It is understandable that with such a wheel as this the wires can be twisted in an exceedingly shorter period of time than by the more laborious and tedious manner just described.

The wire trade does not vary from other industries in so far as the various modes of procedure connected with it are concerned; for it may happen that several shops have different processes which they are in the habit of following for the manufacture of the same description of articles. When a master, foreman, or workman hits upon an idea for obtaining by a new method certain results in a particular direction, it is the earnest desire of all connected with that shop to keep such as a secret from outsiders: thus it happens that a description of certain work performed in a certain manner in one shop would be scorned by workmen in some other places, for the simple reason that they are used to doing things somewhat different. Sometimes it will be found that a majority of shops follow a particular method, and wonder is created as to how it is that the minority are ignorant of their fellow-workmen's procedure. Why is it? Because each shop jealously guards its acquired knowledge, and thinks that but a few possess the same information; and if it were not for the fact of workmen leaving one shop and entering another and communicating the secret to their new fellow-workmen, such trade items would still remain unknown to outsiders.

I have slipped these few notes in because it has just struck me that some wire-workers may find that many of the modes here described differ somewhat from those they may have been used to following to obtain the same results.

**Gridirons.** — The homely gridiron is a very useful article, but its brother, the steak-toaster (honoured by other names as well as this), excels it in a great measure. The first is made, like the proverbial cat is killed—in more ways than one. A few years ago a man used to parade the streets with a quantity of stout, straight wires in his possession, and when he had collected an appreciative and apparently speculative audience, he commenced work by taking a straight wire from his bundle, quickly twisting it this way and that way by the humble aid of his fingers only, and in almost as little time as it has taken me to speak of him, he had formed a gridiron similar in appearance to that shown in Fig. 145. He certainly deserved what he obtained—a ready sale for his impromptu manufactured goods.

*Their Formation.*—I am not going to ask any of my readers to perform the task in this manner, although it is really not a difficult one; it was the celerity with which the man accomplished his work which surprised his onlookers. A block, similar to that represented in Figs. 142, 143, and 144, will be required for accurate work. A straight

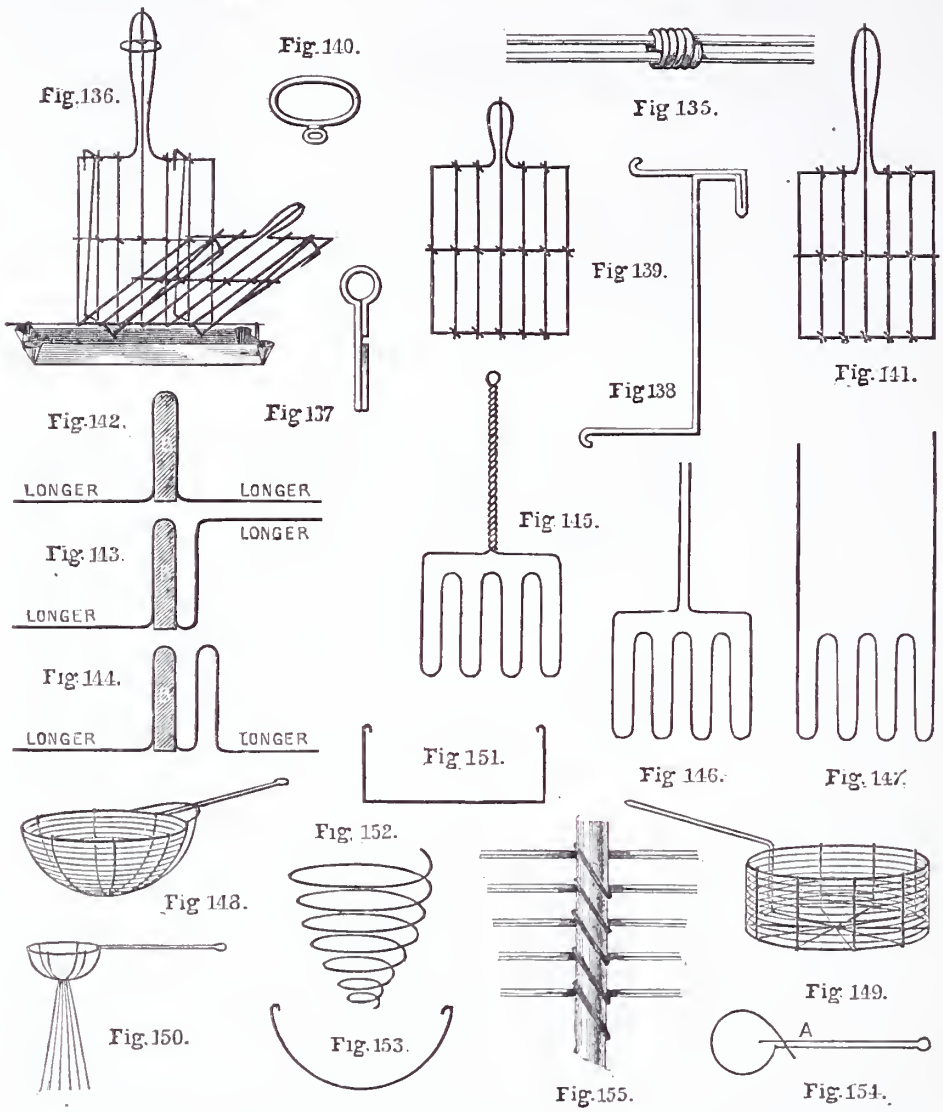

**Fig. 135.—Hinge for Steak-Toaster. Fig. 136.—Steak-Toaster. Fig. 137.—End of Gridiron Handle. Fig. 138.—Hook for Steak-Toaster: four required. Figs. 139, 141.—Frames of Steak-Toasters. Fig. 140.—Drop Catch for Toaster. Figs. 142, 143, 144, 146, 147.—Various Stages in Formation of Gridirons. Fig. 145.—Gridiron. Fig. 148.—Vegetable Ladle. Fig. 149.—Alternative Pattern for ditto. Fig. 150.—Lacing Wires hanging loosely on Handle. Figs. 151, 153.—Framework Wires of Square and Round Ladles. Fig. 152.—Ladle Spring. Fig. 154.—Ladle Handle, etc. Fig. 155.—Section of Ladle.**

wire would first be bent round it as in Fig. 142, in which diagram B is the block. The wire would then be reversed and bent round the block as in Fig. 143. Next it would again be reversed and bent, as in Fig. 144. These operations would take place until the sufficient number of bends had been accomplished. It would then appear as in Fig. 147.

Each clear portion at the sides would then be bent twice, when the shape would be as in Fig. 146. These bendings would be performed by means of a peg driven into the bench. The longer portion would then be shown in Fig. 140. The latter is attached to the wire just mentioned by means of the small eye in it. The front frame is secured to the back one by having three or four pieces of wire twisted around both, as in Fig. 135, thus forming hinges for them. When the steak or other commodity is to be cooked, it is placed between the frames, and the ring wire which travels up and down the longer handle falls over the shorter one, and retains both frames firmly together.

*Gravy Pan, etc.*—Between the frames at the bottom is placed a long loose wire, the ends of which pass through holes or staples handle inclusive, and is turned over in the usual way. Four other wires, two at each side of the long one just alluded to, are also turned over on to the frame, and duly laced, in addition to the latter. Five wires are sufficient for the front frame, and will be turned over and laced similarly to the others. Sometimes a lesser or a greater number of wire bars are used, but the number I state will be conveniently suitable. Across each frame will be a stay bar, also laced in position to strengthen the article.

*The Hooks.*—My notes on hooks in my paper on "Fire-Guards," recently published,

Fig. 168.—Side Elevation of Prong. Fig. 169.—Completion of Figs. 164, 165.**

again bent round a large peg or small block, as in Fig. 137, the further end of it being so placed that it may be parallel to the longest part of the remainder of the wire. The shaft would then be held firmly together by means of a wire twisted around it, or by a strip of tin being similarly twisted.

**Steak-Toasters.**—Let us take steak-toasters—pardon me, dear reader, should the pronunciation of these words result in a slip of the tongue. These articles are made in two separate movable frames, opening from the bottom similar to a book, the handle of one frame being much shorter than that of its fellow frame. Between the wire forming the longer handle runs a straight wire, upon which travels a ring of the shape in a tin tray or gravy-catcher. On each frame are two hooks, their purpose being to hold the toaster to the bars of the grate at which the delicious morsel within is to be cooked.

*The Frames.*—The shape of the front and back frames respectively are shown in Figs. 139 and 141. The wire composing each is bent round pegs to the required pattern, the handle being formed either round a block or by the aid of the pliers. It matters little at which point the ends of the wires finish to form these frames, but the corner I show will be as suitable as any. Then, both ends are either twisted around each other or simply hooked. A middle wire in the back frame traverses the whole length of it, will give all particulars necessary to the formation of the hooks which are required for steak-toasters, the difference between the two patterns being that the latter are much longer, have no intermediate eye-holes, and have a longer bottom bent portion, in contrast to the former. When they are fixed by having their ends squeezed down over the bottom and top wires of the frames respectively, the lower parts of them project and are the means of keeping the toaster's frames away from the bars of a grate.

**Ladles.**—Two of the commonest forms of ladles used for various purposes in connection with vegetables are shown in Figs. 148 and 149. I will take the form represented in Fig. 148 for our first consideration.

The frame of it is shown in Fig. 150. The handle, etc., are made from one length of wire, so bent that the ends of it meet at a point near the part marked A in Fig. 154, where they are secured in the usual manner. To the circular portion of it are then attached two, three, or more nearly half-circular wires, so fastened that the knuckles of them are inwards.

*The Framework and Spring.*—Each loop or bend is so fixed that it crosses the others at a point terminating in the bottom of the article; and between each pair of knuckles the space must be exactly the same. The inside consists of a spiral spring (Fig. 152). I must ask my readers to refer to my article on "The Worm Block" in another number for particulars of the procedure adopted in producing spiral springs. As I there say, the spring will be extended in width. In fixing it to the ladle frame the lower end of it is tied or squeezed over the junction of the hoops, while the other part of it is placed properly within these hoops; and the top end, when cut at the right spot, bent over on to the circular top of the framework. It requires a little care to fix the spring neatly and accurately; but the operation cannot be said to be at all a difficult one to accomplish.

The spring has to be laced in position. It is usually the case that the necessary number of lacing wires are tied to the junction at the bottom of the ladle preparatory to their being finally secured. Each one is then worked along that portion of the ladle frame to which it is adjacent, and fastened off properly to the top of the frame. The second, third, and so on, are afterwards similarly treated, but each one is completely finished off before another is commenced; otherwise the lacing will not be done satisfactorily.

*Strengthening Wires.*—To give strength to the article, there are generally three extra wires attached; one passing from the handle to the bottom of the ladle, and each of the remaining two joined respectively to the straight and circular portions. The under one is sometimes straight.

*Second Kind of Ladles.*—The second form of ladle is perhaps the best for most purposes, on account of its having a flat bottom, thus enabling the user of it to rest it upon anything without fear of its toppling over, or the contents of it tumbling out, which would always be the chance if the round-bottomed ones are used. The remark that was made by Handy Andy concerning soda-water bottles, which he was pleased to say had no bottoms because they would not stand up, has just struck me; and I feel that I ought to follow the example of such a curious authority, and not allow myself to term any part of the first ladle as *round-bottomed*; and in truth there is something philosophical in Andy's ideas, for whoever would dream of speaking of the *bottom* of the world? But there! one must have names for things and parts of things, although a still higher authority has said, "What's in a name?" therefore I term them round-bottomed.

*Framework, etc.*—For the ladle shown in Fig. 149, a frame of the pattern there shown is necessary. My notes upon the round-bottomed articles can be applied to the construction of the flat-bottomed ones in every respect, with the exception that the under parts are shaped as in Fig. 151, and the handle sometimes bent as in Fig. 149. A spring is fitted within in a similar manner, the proper portion of it being flattened against the bottom of the ladle. The lacing will also be the same. Here I might remark that in Fig. 155 I have shown a section of a ladle when laced.

## A USEFUL METAL LATHE.

BY SELF-HELPER.

Preparing Hand-Rest—T's—Fly-Nuts—Bed—Fly-Wheel—Crank—Pitman—Treadle—Driving Band—Conclusion.

The *Hand-rest* casting may now be taken in hand, and is usually found to contain a good deal of sand and grit in the T-slot.

This should be cleaned out as well as possible, and the head of a half-inch bolt filed so that it could run easily from end to end. Sometimes little knobs of metal are found in castings, and if one of them is in the slot, it might cause a great deal of trouble, and should be now removed with a file. The sole of the rest must be made true, either with a file, or, what I find very efficient, a good grindstone. Of course, if it could be planed or milled, so much the better. The hole for the shank of the T-rest may now be bored. It is important that it should be at right angles with the sole, and to secure this the best plan is, I think, to clamp the rest against the face-plate of the working lathe, and bore the hole with a drill pressed forward by the back centre, or held in the slide-rest. A light cut taken off with an inside tool would true it still farther. A 6 in. centre lathe, or one swinging so much in the gap, would be required for this; but those who cannot get the use of such a tool may make a very good job by drilling the hole to a smaller size, and then enlarging it with a reamer. The hole, when finished, may be $\frac{7}{8}$ in. or $\frac{7}{8}$ in. in diameter; preferably the latter, if the shanks of the T's will turn up to that size. A little hole, $\frac{3}{8}$ in. in diameter, may now be drilled in the projection *b* (Fig. 10, page 453), and tapped to take a steel set-screw with a hardened point. Better arrangements for clamping the T-rest are sometimes employed, but this plan will do for all practical purposes.

T's.—With regard to the T's themselves, it is not easy sometimes to turn their stems, owing to the absence of a centre at the upper end; but if the amateur himself makes the patterns, he has it in his power to leave a projection which will take the centre during the turning, and can afterwards be removed. I turned a set of wrought-iron T's once by cutting a channel across a piece of wood screwed to the face-plate into which the top of the T went, the other end being supported by the back centre. This channel will not be across the centre of the wood, but will deviate more or less, according to the forward cant of the T. Some makers of cheap lathes have solved the difficulty of fitting the hand-rest by putting a cored hole in the support, and casting the T-stalk small enough to fit into it; the only fitting then necessary is the set-screw, which is one of the square-headed sort, at so much a gross. As we are not makers of cheap lathes, such a proceeding would be unworthy of us; but the suggestion may be worth something to a man whose spare time is limited.

With regard to the *set-screw*, it would be well to have its head spherical, with a hole across for a tommy; and if a fixed tommy, like a vice handle, were put in, it would be found very convenient.

*Fly-Nuts.*—At this stage the *fly-nuts* will be prepared. Holes must be bored in the bosses for tapping—$\frac{1}{2}$ in. for the hand-rest and $\frac{5}{8}$ in. for the poppet. If, however, the poppet is attached by means of a nut overhead, the fly-nut for the hand-rest only is required.

The hole being bored and tapped, it would be well to take a cut off the upper surface of the boss. This may be done by running it on the tap, or on a mandrel screwed for the purpose, and putting the latter between the centres of the working lathe. The surface so treated should not be quite flat, but slightly spherical, the centre thus bearing first upon the clamping-plate. It is scarcely necessary for me to say that the clamping-plate should have a hole made in it large enough to let the bolt pass freely through.

*Mounting.*—The heads of a lathe are of little service without being mounted, and so the bed, fly-wheel, treadle, and crank next demand our attention.

The character of the mounting may be determined by the success or non-success of the work so far completed. If the heads are worthy of it, a planed bed and turned fly-wheel may be got from some of the lathe-makers who advertise in the pages of this Magazine; whereas, if the heads have been put together in any sort of a way, and it is questionable whether they will ever work at all, the roughest wooden bed and fly-wheel may laugh them to scorn.

*Bed.*—A wooden bed is not by any means to be despised. If a piece of beech or mahogany, 2 in. thick and 4 in. or 5 in. wide, well seasoned and straight in the grain, can be got, it will make a very good bed. The top would be the better of being plated with iron $\frac{1}{4}$ in. thick, which could afterwards be filed smooth and bright; or T or L iron might be used, and a good strong section will serve well. In any case, the upper surfaces and inner edges should be as nearly straight and true as possible. A reference to my former papers on lathes in Vol. I. of Work will teach a good deal as to the mounting of these heads.

*Fly-Wheel.*—It would be a distinct advantage to have a fly-wheel with several steps, as a piece of work of small diameter ought to be driven much faster than a larger piece. Such wheels can now be procured either cast in the rough, from 4s. or 5s. each, or turned, bored, and key-wayed, from £1 to 30s. The last-named run much smoother, and are well worth the difference in price.

A wheel about 26 in. in diameter at the largest step would get up a good speed, and if there was a small step of about a foot in diameter, a considerable amount of metal-turning could be successfully accomplished in this lathe.

*Crank.*—The crank best suited to a wood-turning lathe would, I think, run on centres passing through the legs, as such a plan produces very little friction. The centres of the crank should, however, be bushed with hard steel, as otherwise the points on which they run are apt to produce distorted holes.

The crank should be turned, at least where the fly-wheel comes, and, if appearance is aimed at, all over. A part very important, but usually neglected, is where the hook of the pitman goes. If this cannot be turned, and it is not easy to do so without some special apparatus, it should be filed with the aid of a semi-circular template, cut from a piece of tin or sheet iron to the size of the part on which the hook goes.

The bearing part should be about an inch long, and the hook of the pitman made of flat steel turned over to fit, tempered and hardened. The entire pitman need not be steel, a chain or piece of bent $\frac{3}{8}$ in. iron doing nicely for the lower part.

*Treadle.*—The treadle could well be a

light frame of iron, pivoted, like the crank, to the back part of the legs, or attached with hinges to a bar running from leg to leg, as I formerly described.

A wooden footboard would be attached to the front of the treadle, to take the pressure of the foot during pedalling. The throw of the crank is an important item in small lathes. It should not be more than 2½ in. from centre to centre, which will cause the foot to move 9 in. or 10 in. A higher stroke than this is unpleasant, and causes the lathe to jar.

*Driving Band.*—The best driving band for any high-class lathe is certainly gut, which is secured with hooks and eyes at the ends. It may be shortened or lengthened by twisting the gut more or less. The hooks and eyes are screwed into the ends, and if a portion protrudes into the eye, it is charred off with a hot iron.

*Conclusion.*—If any of my readers make this lathe as it should be made, they will have a tool which will be a credit to them, and do work during their whole life.

I will be most happy to answer any questions on lathe building, or supply any details which I may have overlooked, through the medium of "Shop."

## PHOTOGRAPHY AS A MEANS OF HOUSEHOLD DECORATION.

BY WALTER E. WOODBURY.

### Transparencies.

According to a statement in a contemporary, there are at present upwards of 20,000 amateur photographers in the United Kingdom. When one considers, however, the pleasures to be derived from the art, the figures do not seem so startling. During my life I have met with many hundreds of persons who have taken up with photography as a pastime, and it has often struck me that there are few—a very few indeed—who ever try to turn their work to any useful account. They go through a lot of trials and inconveniences to master the art, and this done, their only desire seems to be to make a lot of silver prints of inferior quality, and stick them in an album. This album usually becomes the terror of their friends, as they are usually compelled to look through it upon each occasion of their visit, and have recounted to them by the amateur scores of hair-breadth escapes and awful and appalling difficulties which had to be encountered—usually told as apologies for the defects which are so plainly visible. I have been a victim of this kind several times, and having some slight knowledge of photography, have often smiled to myself at the awful crams of the "dreadful amateur photographer."

Now, there are so many ways nowadays that photography can be employed for really useful and ornamental purposes, that it really seems a pity that the amateur does not turn his attention to some of them; then, instead of being a nuisance to his better half (if he is fortunate enough to have one, of course) with his "nasty messy chemicals," he will be able to assist her in the ornamentation of the home. In order to be healthy and happy it is necessary that we be surrounded by beautiful things. If we are not fortunate enough to live in a part of the world where we can have trees, flowers, and beautiful scenery, we can at least have representations of them.

Now, in my opinion there is no pastime which affords so much pleasure and genuine satisfaction as that which leaves permanent records of ingenuity and skill. Every time we glance at some useful or pretty object, the construction of which has employed our leisure hours, the pleasure is revived. We recollect the difficulties we encountered and the energy with which we vanquished them, and thus gratification and delight are kept ever green. When, too, a friend rapturously admires some work of art over which we have spent days or weeks of time, with what pardonable pride and self-gratification is the heart filled when we remark in a cool, off-hand manner, "Oh yes, I made that myself," so that the friend will be led to imagine that to you the thing was a very simple task.

I do not think there is any art which lends itself as readily to so many applications. A member of our royal family has already discerned this. H.R.H. the Princess of Wales is an ardent amateur photographer, and has recently had constructed for her a china tea service decorated with views of Scotland made by herself. It is not, of course, possible that every reader of this Magazine is in a position to have 100-guinea tea services made with their photographs; it is my intention, therefore, to show how photography may be used in decorating the house, adding pretty ornaments, or converting unsightly objects into attractive ones, and all this without any very expensive outlay.

The first things we require are good and suitable negatives. Sometimes by scientific treatment indifferent negatives may be made to yield passable results, but it is always best to start with a firm and perfect base. The negative is the foundation, and, provided it be good, it will not be difficult to make almost anything we require from it. Let the amateur select, then, the best negatives he has in his possession.

*Transparencies.*—The first process we will consider is the manufacture of transparencies or positives on glass. There are many processes by which these can be made, the simplest being the exposure of an ordinary bromide dry plate under a negative to a gas flame, and developing with the pyrogallic or ferrous oxalate developer, the former giving brown tones, and the latter black. About the best plates for this purpose are the Paget Prize Plate Co.'s XXX plates. Chloride of silver emulsion plates, specially manufactured for lantern slides and transparencies, will be found to give better results than ordinary bromide plates. A great deal depends upon the colour of the transparency, and this is usually dependent upon the developing agent. To get warm black tones, use the following:—Solution I.: Potassium citrate, 200 grs.; potassium oxalate, 60 grs.; potassium bromide, ½ gr.; distilled water, 1 oz. Solution II.: Ferrous sulphate, 80 grs.; sulphuric acid, 1 minim; distilled water, 1 oz. Add these two solutions in equal parts before required for use. Another developer that gives very nice warm tones is this:—Solution I.: Magnesium carbonate, 76 grs.; citric acid, 120 grs.; common salt, 2 grs.; distilled water, 1 oz. Solution II.: Ferrous sulphate, 140 grs.; sulphuric acid, 1 minim; distilled water, 1 oz. In exposing the plate it should be laid on a printing frame behind the negative, and held about one or two feet from a gas burner. The exposure can be tested with pieces of emulsion paper usually sent out with the plates. No rule for it can, of course, be given, as it varies according to the quality of the negative, the rapidity of the plate, the strength of the illuminant, and the distance from it.

Perhaps the finest method of making glass transparencies is by the carbon or autotype process. This process is based upon the peculiar action of gelatine mixed with an alkaline bichromate to become insoluble when exposed to the light. Sheets of paper coated with gelatine containing a suitable pigment are required. These are obtained from the Autotype Company, and may be had either plain or sensitised. If purchased ready sensitised it should be used as soon as possible, as it does not retain its good qualities for any great length of time. It is better to purchase unsensitised carbon tissue for transparencies, and sensitise it in small quantities as required. This is done by immersing it for two minutes in hot and three minutes in cold weather, in: Potassium dichromate, 1 oz.; liquor ammonia sp. g. ·880, 5 drops; distilled water, 20 oz. It is then dried and preserved in an air and damp-tight box. In printing, pieces are cut to the required size and laid behind the negative on the printing frame. The action of the light being invisible, an actinometer will be necessary to judge of the right exposure. It will be necessary to print much deeper than for ordinary carbon prints, as the images are to be viewed by transmitted light. While the printing operation is taking place the glass to receive the picture can be prepared. This should be of good quality, colourless, and free from bubbles and defects of any kind. It is first well cleaned, and all trace of greasiness removed. It is then coated with a solution made as follows:—Soak one ounce of Nelson's gelatine in one pint of cold water, and when thoroughly swelled, place the vessel containing it in a pan of hot water, and gently dissolve it. Next add sufficient potassium dichromate to give it a golden sherry colour, vigorously stirring the solution the whole time the addition is being made. While warm the glass plates are coated with it and dried in the daylight. We have now the exposed tissue and the prepared glass. These are both placed under water. The tissue, after it has curled up, and again become flat, is laid face downwards upon the gelatine surface of the glass, and the two are withdrawn from the dish. The tissue is then pressed well into contact with the glass by the aid of an indiarubber squeegee. They are then placed between blotting boards for a few minutes, and afterwards immersed in a bath of hot water raised to a temperature of about 105 deg. Fahr. When the pigmented gelatine begins to ooze out from the edges it will be found possible to strip away the paper which had supported the gelatine, leaving most of the latter upon the glass plate. By next laving the warm water on the glass plate all the soluble parts of the coloured gelatine may be washed away, leaving an insoluble picture firmly attached to the glass. It may be found necessary to increase the temperature of the water slightly, especially if the tissue has been somewhat over-exposed. As soon as development is complete, or, in other words, as soon as all the soluble gelatine has been washed away, leaving the image perfect and clear, the plate is thoroughly rinsed under the cold water tap and placed in a bath of: Powdered alum, 1 oz.; water, 20 oz. This has the double effect of hardening the gelatine and discharging the yellow colour produced by the dichromate salt. This glass plate, with the image, is now well washed in cold water, and, when dried, is ready for mounting. This is done by first procuring a piece of ground glass and binding the two together with thin black

gummed paper. Small thin strips of cardboard should be fixed round the edges to prevent the two surfaces from touching.

Transparencies produced by any of these processes can be fitted into neat brass frames made for the purpose, and, if hung in a window, form a very pleasant relief to the eye. Indeed, the windows offer a very large and attractive field for decoration. If a room is nicely and tastefully furnished, the blank left by the window is in many cases a shock to the eye unless it looks out upon a lovely and pleasing scene. In order to relieve this, a framed transparency hung in the window often acts like a charm. Fig. 1 will give some idea of the appearance of a transparency framed complete.

Fig. 2.

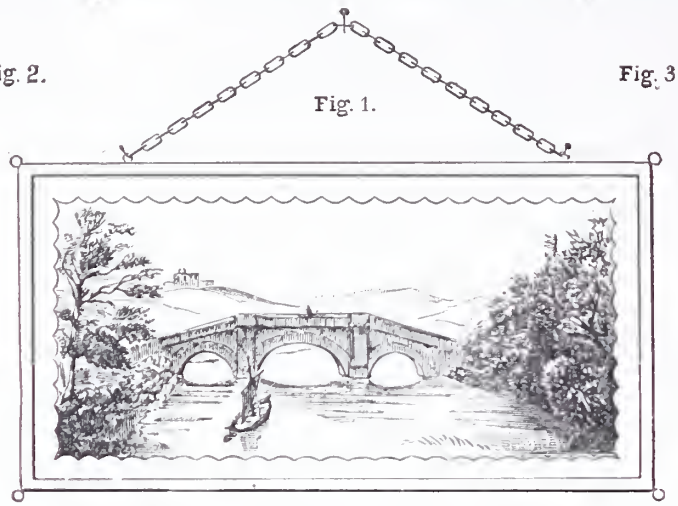

Fig. 1.

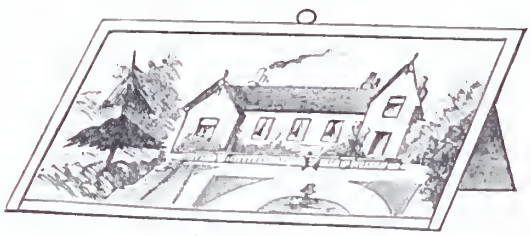

Fig. 6.

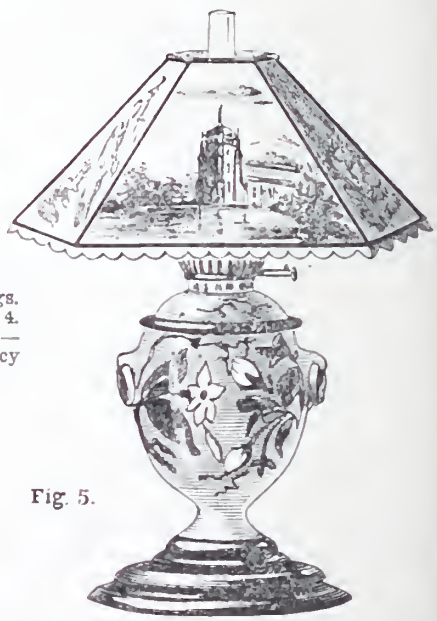

Fig. 5.

Fig. 1.—Framed Transparency to hang in Window. Figs. 2, 3.—Window Sashes treated as Transparencies. Fig. 4.—Hanging Lamp formed of Transparencies. Fig. 5.—Lamp Shade of Transparencies. Fig. 6.—Transparency framed with Sap.

There are few, I fear, who have the good fortune to dwell in a house the windows of which all have pleasant outlooks. In London we are often driven to gaze for ever upon extensive and decidedly unpicturesque views of tiled roofs, smoking chimney-pots, etc., occasionally relieved by the appearance of a few stray cats in search of a convenient place to hold their nightly concerts. These unsightly windows are often filled in with coloured glass or transparent paper, which, unless of superior and costly quality, rarely present any very pleasing effect. Much superior is the photographic transparency. By inserting positive transparencies produced by any of the methods previously described, and fixed in with putty, the distasteful view of chimney-pots entirely disappears without the light being obstructed to any very serious extent. Figs. 2 and 3 will give some idea of a window before and after this treatment.

There are a variety of other uses to which these transparencies may be put. The ordinary hall lamp will rarely suffer by the removal of the glass panes and the insertion of artistic glass views. Fig. 4 will give some idea of a lamp thus decorated, or a very effective lamp shade for an ordinary lamp may be made with a little ingenuity. Any brass-worker will construct the framework, when the transparencies have only to be cut to the required size (see Fig. 5). Smaller shades can be made, and are very effective for a card table or reading candles.

There is one special point to be noted in the manufacture of these ornaments which are subjected to heat—the glass used must be of a good quality and free from air-bubbles; and, further, it must not be made to fit too tightly in the framework, otherwise the expansion by heat will crack it.

I am fully aware that I have not yet enumerated one-half of the uses to which these transparencies may be put for household decoration, but the ones I have given will, no doubt, suggest many others to the reader.

We will now pass on to the uses of ordinary silver prints for our purpose. Every amateur knows how to make these, so no instructions will be necessary. Silver prints, however, even when mounted on cardboard and rolled or burnished, do not form a very attractive ornament. They soon curl and twist about into all sorts of shapes, and appear also to collect all the dust and dirt that is possible. A very effective way of showing off photographs is to mount them in optical contact with glass. The bevelled glass, with backing of leatherette paper leg to stand upon, with a ring to hang to the wall, can be purchased complete, it only being necessary to mount the print. This is done in the following manner:—After the prints have been toned, fixed, and well washed, the superfluous water is blotted off and they are placed between blotting-boards under pressure to dry. Now soak about 2 oz. of gelatine in cold water until it is all swollen, then add sufficient boiling water to make a thickish solution. When all the gelatine is dissolved, filter the solution through a piece of fine muslin or flannel into a porcelain dish standing in a hot-water bath, the temperature of the gelatine solution being kept by this means at about 100 deg. Fahr. The glasses are thoroughly cleaned, all trace of greasiness removed, and the gelatine solution carefully skimmed to remove all bubbles and scum. A print is now laid in the gelatine solution, avoiding the formation of bubbles, and when quite soaked it is removed and laid quickly on to the glass plate. With an indiarubber squeegee it is next pressed well into contact with the glass, and then allowed to dry. The prints should be cut slightly larger than the glass plates, so that after they are dry they can easily be trimmed with a sharp knife to the exact size of the glass. The pictures are made more effective if vignetted or masked, so as

to leave a white margin all round the edge of the glass. When the protective backing has been pasted on they form very artistic ornaments for the mantelshelf or sideboard (see Fig. 6). This method of mounting the print adds considerable brilliancy to it, and also serves to protect it from dirt or atmospheric influences.

## SOMETHING MORE ABOUT SUSSEX "TRUGS."

BY "CHOPSTICK."

INTRODUCTION—KIND OF WOOD REQUIRED—THE WALKING-STICK "TRUG"—THE "CAUL" OR WOOD "TRUG"—THE STABLE OR FEEDING BASKET—THE COAL BASKET—THE LADIES' WORK BASKET—DO., WITH FOLDING HANDLES—THE PARCEL-POST BASKET—FLOWER POT—DOLLS' CRADLES—BUTCHERS' TRAYS, ETC. ETC.—CONCLUDING REMARKS.

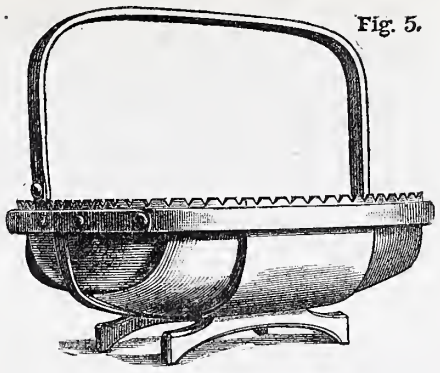
*Introduction.*—The number of letters and inquiries I have received since my previous paper on Sussex "Trugs" appeared in WORK (see No. 85), encourages me to think that the readers of that paper take some interest in the subject, and as I have reason to believe there has been, or will shortly be, several manufacturers starting in the business, I will endeavour to describe some other very useful, and also some very ornamental, forms of the "trug."

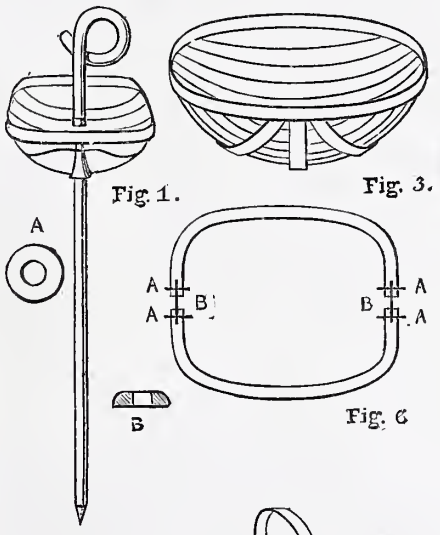
*The Kind of Wood Required.*—In my former paper I mentioned chestnut, and ash for the rims and handles, and "sallow" for the boards, but these seem to be difficult kinds of wood to obtain in some parts of the country; or, at any rate, the chestnut and sallow are. The ash, I should think, could be obtained anywhere. I have been asked by several correspondents to mention a substitute, but that is rather a difficult matter to do, though I think that alder might answer; but, again, I am afraid that would be as difficult to procuro as sallow.

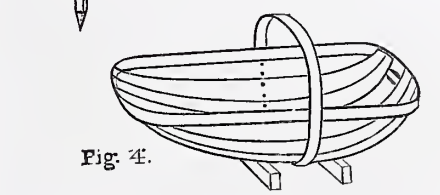
I mentioned the American bass or white wood to one of my correspondents, though whether that would cleave or not, I do not know. If my readers can find no wood suitable, I would advise them to get the toughest wood they can find, and get it sawn into boards as thin as possible. This will require more care in putting the boards in, but otherwise I do not see why it would not answer as well as the cleft boards.

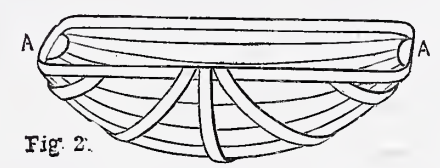
*The Walking-Stick Basket* (Fig. 1).—This, I think, is one of the latest novelties brought out in the "trug" line. Visitors to the Edinburgh Exhibition will remember it at once, as it was exhibited there. It is simply a combination of the trug with a walking-stick, and is very simple to make. First make the trug part, as per instructions in my former paper; only make it about 8 in. in diameter each way. Then make the stick, which is a straight piece of ash with the crook on the top, formed by steaming and bending in the same way as the rims and handles; then cut a hole in the bottom of trug, so as the stick will just go through; but before fixing the stick in, get from a turner's (if you cannot turn them yourself) two collars, as shown in Fig. 1, A (plan), and Fig. 1, B (elevation). Fix one of these on the stick, about 6 in. below the crook; then place the stick through the hole in bottom, so that the collar fits in the trug; then slip the other collar on the point of stick, and fix up close with a small nail, and the walking-stick is complete.

And now a few words as to its use. It is sold very largely in places frequented by tourists, who use it for fern and flower gathering, etc.; by geologists, for collecting specimens; by ladies, for fruit picking; and for many other uses too numerous to mention.









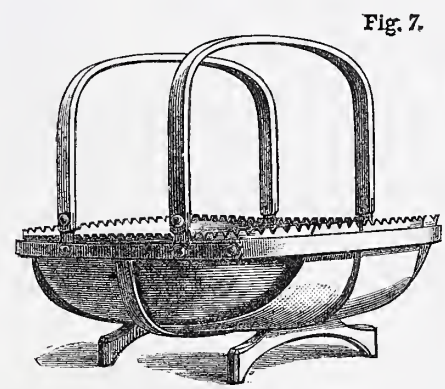


**Fig. 1.—Walking-Stick Basket—A, Collar; B, Section of ditto. Fig. 2.—"Caul" or Wood Basket. Fig. 3.—Stable or Feeding Basket. Fig. 4.—Coal Basket. Fig. 5.—Ladies' Work Basket with One Handle. Fig. 6.—Detail of Folding Handles—A, A, Rivets; B, B, Small Pieces of Tin to form Hinge. Fig. 7.—Ladies' Work Basket with Two Handles.**

*The "Caul" or Wood Basket* (Fig. 2).—This very useful basket I need say but very little about, as far as instructions for making are concerned, as it may be described as a trug of the common kind, only of larger growth. It is made from 3½ ft. to 5 ft. long; and as this would be a very unwieldy burden for one to carry, the handle is dispensed with, and instead a hand-hole is cut at each end, just under the rim (A, Fig. 2). This enables one person to take a firm hold of each end, and carry a considerable load of firewood or coal, or whatever it is being used for. You will notice that it has a rim the same as an ordinary trug, and instead of the handle going over the top, it stops at the rim, to which it is nailed. There are also two other rims (or rather braces, as they are called) on each side. The boards are thus nailed in five different places, which makes it very strong and durable.

*The Stable or Feeding Basket* (Fig. 3).—This form of trug has, I believe, been sold in thousands since its introduction a few years ago. It is, as its name implies, for the purpose of feeding cattle and horses in their stables, and is largely used by the army. I think this fact will convince anyone of its usefulness. It is made in the same way as the trug, except that it is quite round, and about 20 in. in diameter, the framework consisting of the rim and three braces, as shown in the figure. Further instructions are, I think, unnecessary, so I will pass to—

*The Coal Basket* (Fig. 4).—This is very similar to the common trug, except that it is made smaller at one end than the other, and the handle is placed closest to the wide end. A hole is also made under the rim at the wide end, in the same way as in the caul basket. This makes it very convenient for the purpose it is intended for—viz., to throw the coal on the fire, and thus dispense with the ordinary coal-scuttle and shovel. As this basket is made the same as the common ones, instruction is unnecessary.

*The Ladies' Work Basket* (Fig. 5).—These very handsome baskets are in great demand wherever shown, and are also used for many purposes, as well as the one mentioned. They are made in various sizes, ranging from 5 in. in diameter to 15 in., and are ornamented in various ways. I think, perhaps, I cannot do better than give a few detailed instructions for the making of these. The rims and handles are made on blocks in the same way as the common variety, but, of course, more care must be taken with the work, and they must be made much lighter. The boards also must be shaved as thin as possible, and a good finish is given to the basket by nailing them together with silvered upholsterer's nails. After the boards are put in, they should be trimmed round, about ⅛ in. above the rim, and then small notches cut with the knife. This gives the basket an ornamental appearance, without requiring much time to be spent on it. A good effect is also given by staining each alternate board a different colour. Needless to say, this must be done before the boards are nailed in.

These baskets are much improved by making the handles to revolve, or, more properly speaking, to fold down. This is effected by cutting the handle asunder, just above the rim, and inserting a piece of tin about an inch long, half of it in each part, with a tin-tack through each, which forms a hinge for the handle, and allows it to fold easily.

If I have not made it quite plain, Fig. 6 will explain it clearly. B, B, are the pieces of tin, and A, A, A, A, are the rivets. Figs. 5 and 7 are photos of these baskets, showing them with one and two handles respectively.

*The Parcel-Post Basket.*—This I need say but very little about, as its use is not so general as the other kinds, though for those who send game or fruit, or anything in that way, by parcel-post, it will be found useful. It is simply two ordinary baskets without handles, hung together at one end by the rims, so that, when folded together, they form a box. The rims can be tied together at the other end, which makes all secure. The chief recommendation of this article is its lightness, which saves postage, and its strength, which secures the contents from harm.

*The Flower Pot.*—Very handsome flower pots can be made out of the same materials, and in the same way as the trugs, though, perhaps, they can hardly be called trugs. To make them, first make an octagon out of ½ in. deal, of the size that the inside of the flower pot is wanted: this will form the bottom of the pot. Then make a rim of the same size: this is to fix the boards to at the top. Then prepare eight boards, if a small pot, or sixteen, if a large one, and proceed to nail them, first to the bottom, and then to the rim, with silvered nails; then trim off, and ornament in the same way as I mentioned for ladies' work baskets; and when you see the effect, you will buy no more ornamental flower pots. These can be used either as standing or hanging pots, and can be finished off with enamel, which gives a very pretty effect.

*Dolls' Cradles.*—These can also be made of the same materials, but the trug maker will now have gained such an experience that this and many other useful articles will suggest themselves to his mind; and to take up space in describing the process of making, would only be to waste both my time and the reader's as well, and the same will also apply to the last article on my list—

*The Butcher's Tray*, which is so exceedingly simple to make, that I will leave it in your hands, and pass on to my

*Concluding Remarks*, which will be very few.—In the first place, I wish to mention that, soon after my first article appeared, I received a letter from a firm in the trade, whose intention, I have no doubt, was to get a free advertisement; but if this should meet their eye, they will see that I have mentioned no names, as it would be very unfair to the others in the trade for one to be mentioned and not the others. The firm in question very much wished to know where I got my knowledge, and for their benefit I beg to inform them that I have been through not only their own works, but I believe every other one in the trade. This statement should also give my readers confidence that I know what I am writing about. I have said all I can say about "trugs," but I will repeat what I have said before—that I shall be pleased to answer any queries that may be put to me through the columns of "Shop"; and if this paper brings me as many letters as my former one did, I shall be satisfied that my efforts are, at any rate, appreciated by the readers of Work.

Those who have not yet gained experience in the work by actual manufacture, will note that if the cradle is to rock it will be necessary to put curved rockers under the tray itself, instead of the straight pieces of wood that are generally added to it as feet.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

### 102.—Hodgson's Registered Draught Excluder.

I may begin by saying that ventilation is one thing and draught altogether another, and that although it is imperative to promote and find proper means for securing the former, it is equally incumbent on us to guard against the latter and all the ill-effects which arise from it. A simple and apparently effective appliance for stopping draughts is to be found in "Hodgson's Registered Draught Excluder," the nature of which may be easily recognised from the accompanying illustrations, in one of which—namely, Fig. 1—it is shown in position when attached to a door and the door is closed, and in Fig. 2 when the door is in course of opening. From these it will be noted that the Draught Excluder consists of two mouldings, one of which is attached to the door-frame and the other to the door itself, and as both are fastened to the *outside* of the door, there is no unsightly addition within the room, and the use of curtains or portières, which are often in the way, is rendered unnecessary. It will be seen from the sectional views of the mouldings, which are not very far short of full size, that the one which is affixed to the frame or stop, which forms the uppermost member of the frame, has a hollow taken out along the inner edge or side, and the other has a bead run along the inner edge of the upper surface, which fits closely and with exactness into the hollow in the edge of the first moulding. It is fixed up the sides and on the top, but it is not available for the draught which comes under the door, and which must be cured in some other way. The mouldings, it may be pointed out, are effectual in keeping out dust as well as draught, and are applicable for outside as well as for inside doors and windows. There are no springs, and nothing to get out of order, thus the mouldings are as simple as they are strong and durable. They are easily fixed, and as they are inexpensive, they are within the reach of the poorer sections of society as well as the richer. To fix them, it is first necessary to close the door, and then attach the mouldings to the hinged side, adjusting the same with care, so that it does not rub or bind in any way on the other, and then apply them to the top and opening side in the same way. They have been used by many persons in Settle, Yorkshire, where they were first introduced, and are spoken of by those who have tried them in terms of the highest commendation.

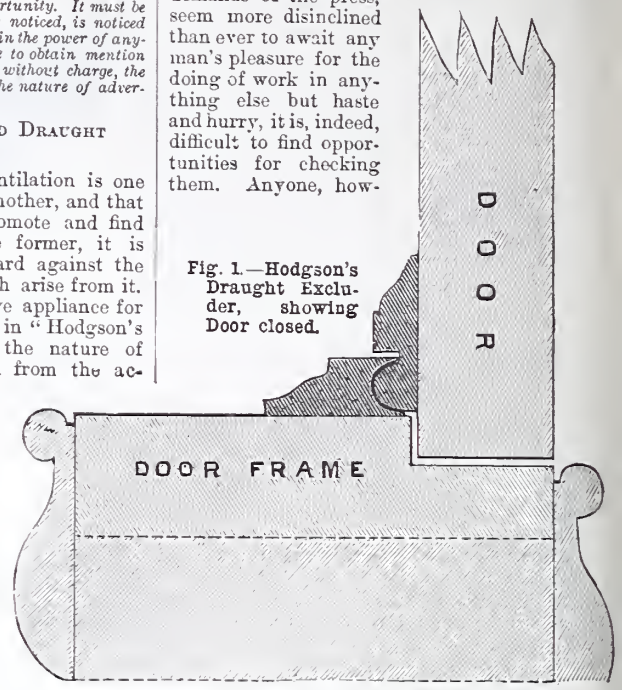

Fig. 1.—Hodgson's Draught Excluder, showing Door closed.

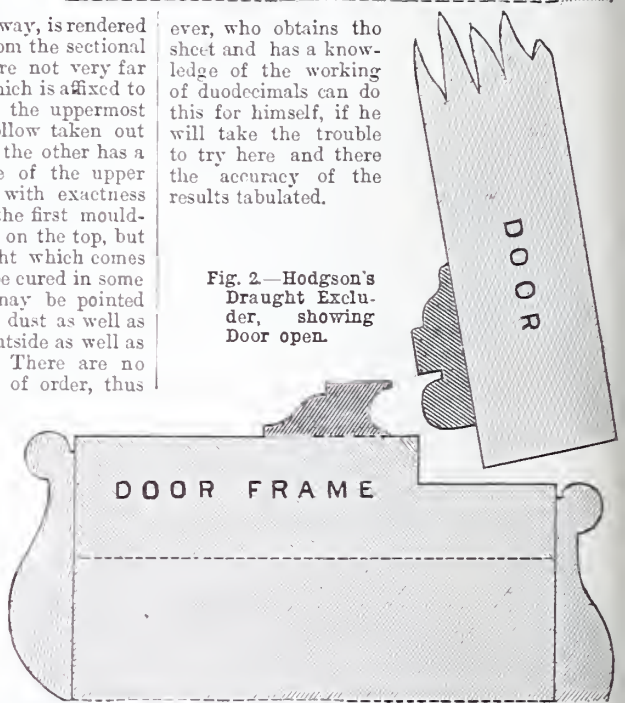

Fig. 2.—Hodgson's Draught Excluder, showing Door open.

### 103.—Tables for Ascertaining Area of Superficies.

In a recent number of Work, a Bradford correspondent inquired for joiners' and builders' tables showing the number of superficial feet in any given measurement of wood or glass. It is a feature that, if carried out at all in trade reckoners, has not been extended hitherto so far as to render the tables in which the matter is dealt with of any great use except in one instance, and that is in a broadsheet issued at a comparatively low price by "The Licensed Victuallers' and Hotel Keepers' Glass and Supply Company, Limited," which is somewhat inconvenient to use, although it is undoubtedly a step in the right direction. The correctness of the calculations given therein I cannot undertake to vouch for, and in the present day, when time and tide and, may I add, the imperative demands of the press, seem more disinclined than ever to await any man's pleasure for the doing of work in anything else but haste and hurry, it is, indeed, difficult to find opportunities for checking them. Anyone, however, who obtains the sheet and has a knowledge of the working of duodecimals can do this for himself, if he will take the trouble to try here and there the accuracy of the results tabulated.

### 104.—"The Amateur."

I have to acknowledge the receipt of various trade journals whose names have been already mentioned in these pages. Among these, attention may be specially directed to "The Amateur." This useful publication, whose utility lies chiefly in its suggestions for the ornamental work that may be so easily done at home in making objects and appliances for its adornment, is still published by Mr. Henry Zilles. It still deals in, and with, subjects for the fret-worker, wood-carver, painter, inlayer, poker-worker, and other work suitable for persons of the class after whom the serial is named, and still holds its own against all comers set on foot to deal with these matters.

The Editor.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Hydrostatic Clock.**—C. W. C. (*Stockton*) writes:—"I here give a brief description and sketch of a clock which I saw at an exhibition at Darlington a number of years ago. I think your readers will not fail to understand it. It was driven by the weight of water in a cylinder which had a spindle through it—each end of the spindle being suspended by thin cord. The cylinder was divided into a number of divisions, each division having a small hole to allow the water to pass from one to the other as the cylinder unwound itself from the suspending cords. So far as I can remember it had to be wound up every twelve hours."—[This idea is no

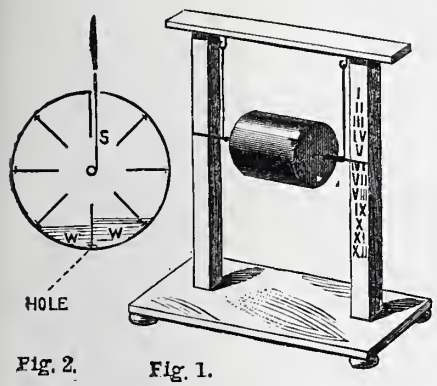

Fig. 2. Fig. 1.

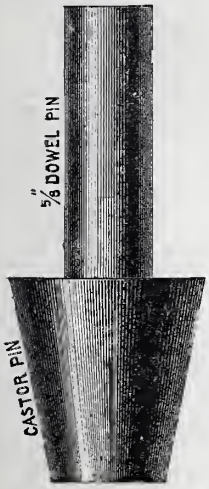
**Fig. 1.—Water Clock Diagram. Fig. 2.—Section of Cylinder, showing Divisions and small Holes in each; also the Water and String (W S).**

doubt ingenious, and the arrangement of the water in the cylinder is curious and interesting; therefore, publicity is given to it in "Shop." As a clock, however, it can only be classed as a "fad." It might tell the time for a week or more, but the winding it up and collecting the water at the right spot, in order to start it at the right point, would be, we should think, a great difficulty. The holes might corrode or get blocked up, and then where would the time be? If a clock of an out-of-the-way kind be desired, a large sand glass would probably be a more correct time keeper. But why go so far into the wilderness when every market is deluged with Walthams and Waterburys?—ED.]



Castor-Pin.

**Worn-out Castor-Pin.**—A. X. E. (*Nottingham*) writes:—"To repair a chair or table leg having a broken or worn-out castor-pin, the following is a good way: Take a piece of birch, beech, or oak, about 4 in. long by 1½ in. by 1½ in., and turn it to fit the castor cup, with ½ in., ⅝ in., or ¾ in. dowel-pin, according to size of leg to be repaired; a ⅝ in. dowel-pin would be suitable for an ordinary easy chair leg. Cut off old castor-pin level with shoulder on bottom of leg; then bore a hole in the centre of leg with a dowel-bit, the same size as dowel-pin, taking care to bore quite true; now fit new pin and glue into leg, then refix castor, and the job is finished. If done carefully the leg will be as sound as when new."

### II.—Questions Answered by Editor and Staff.

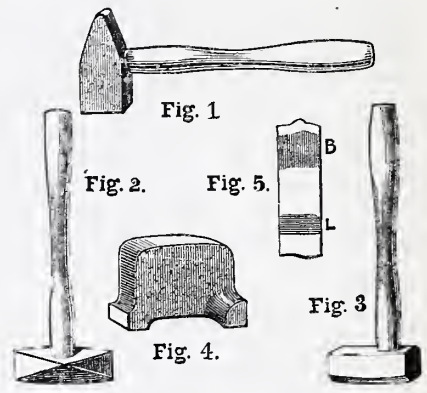
**Driers.**—E. S. (*Manchester*).—"Terebine" is the name given to a drying liquid, which, I believe, was so termed by the original maker, Powers, of Coventry. Every colour and varnish manufacturer, however, now makes a terebine or liquid drier, and its drying strength is usually that of 1 oz. to the lb. of paint, under favourable conditions. Terebine combines far more satisfactorily with linseed oil for drying than does japan gold size, a similar mixture. The latter is most useful in compounding "flatting" and quick-drying paints for varnishing upon. I am unaware of any reliable recipe for making this useful painters' commodity having previously been published; but, through the kindness of Messrs. Mathieson Bros. (Colour Manufacturers, Ardrossan, N.B.), I am able to contribute a simple but thoroughly reliable recipe, which I am further confident will prove very useful and valuable to many professional painters: Take 2 lbs. ground litharge, 2 lbs. red lead, 1 lb. sulphate of manganese, ½ lb. sugar of lead; put all these into a pot, and mix with them four or five gills of pale Japan gold size, until the lot can be easily stirred. Then add about ½ gal. of American turpentine. Now leave the whole to stand, with occasional stirring, for a few days (not less than three), and its materials will act without heat. After the expiration of the few days, the clear resultant liquid—terebine—may be taken off, and more "turps" put on the materials, for the *second* and *third time*, with equally satisfactory results. Half proportions of these component articles may be used with equally good results. Those subscribers, and professional painters especially, who desire to avail themselves of this recipe, cannot do better than write to Messrs. Mathieson for the dry articles named, from which firm all readers of WORK will receive courteous and prompt attention.—F. P.

**Shellac Varnish.**—W. L. C. (*New Cross*).—The subjoined recipe for making a reliable shellac or "spirit" varnish is one coming from a most reliable source, and which, should you determine to act upon it, ought to work out as well as it reads. Take 3½ lbs. orange shellac, ½ lb. gum benzoin, 1 gal. methylated spirits; put all these (or in same proportions for larger or smaller quantities) into a closed stoneware or earthenware vessel. Shake the mixture occasionally, or, if the varnish is required at somewhat short notice, the lac, etc., will dissolve more quickly by slightly heating. The fluid ought then to stand in an open vessel for a few days before being used, and requires, finally, straining through a piece of strong fine muslin or fine wire cloth. "For a cheap varnish for fretwork brackets" you might be satisfied with "Patent Knotting"—or knotting varnish—thinned down, if required, with naphtha or spirits. This gives a good and hard gloss, and dries almost immediately. The recipe above given gives a spirit varnish much favoured by cabinet-makers and fiddle-makers. The small proportion of gum gives a better surface, and also allows more time for working it.—F. P.

**Ox-Gall in Marbling.**—NO NAME.—Our querist on this matter should have stated more particulars, and what marbling process he means, whether on wall-paper, book edges, or painted walls. The subjoined may, however, aid him: *Ox-gall*, when mixed with water colours and pigments, acts as a binding vehicle, but is chiefly noted for the property which enables us, by its addition, to manipulate water mixtures upon polished or greasy working surfaces. *Borax* has the same property, however, and, for many purposes, is preferable to ox-gall. Oils and varnish may be mixed with water more readily by the aid of borax. I conclude you must refer to bookbinders' work.—F. P.

**Velocity.**—KNARF.—Air will flow into a vacuum at the rate of about 1,829 feet per second when the temperature is 60° Fahr. and the pressure 15 lbs. per square inch. I am not aware that this has been directly estimated, but it can be reckoned from the known absolute velocity of a molecule of hydrogen at 32° Fahr., and 29·92 in. Bar., which is 6,097 ft. per second. The velocities of the molecules of gases vary inversely as the square root of their specific gravities. Oxygen is sixteen times as heavy as hydrogen; hence the velocity of the oxygen molecule, for the same temperature and pressure, would be $\frac{1}{\sqrt{16}} = \frac{1}{4}$ that of the hydrogen molecule, or 1,524 ft. per second. Similarly the velocity of the nitrogen molecule, which is fourteen times as heavy as hydrogen, would be 1,836 ft. per second. Taking air as consisting of four parts of nitrogen to one of oxygen, the velocity of air molecules will be 1,774 feet per second at 32° Fahr. and 29·92 in. (= 760 mm.) Bar. You do not say what is the temperature and pressure of the air you are working with. If different to the above, you can reckon out the velocity from the general formula which applies to all gases—viz., $v^2 = 3\frac{p}{d}$ where $p$ is the pressure and $d$ the density of the gas; but the same fundamental units must be used for both $p$ and $d$. At 60° Fahr. and 2,160 lbs. per square foot (= 15 lbs. per square inch) pressure, the density of hydrogen is 0·00528275 lbs. in a cubic foot. Hence $\frac{p}{d} = \frac{2160}{0{\cdot}00528275} = 408{,}878$ in gravitation units, and if the intensity of gravity be taken as 32·2, then $v^2 = 3\frac{p}{d} = 1{,}226{,}634 \times 32{\cdot}2 = 39{,}497{,}615$, and therefore $v = 6{,}284{\cdot}7$. At ordinary temperature (60° Fahr.) and pressure (15 lbs. per square inch) the velocity of the hydrogen molecules will be 6,284·7 feet per second. Using this figure in place of 6,097 as above, we find that the velocity with which air will flow into a vacuum is 1,829 ft. per second at 60° Fahr., and 15 lbs. per square inch pressure.—F. B. C.

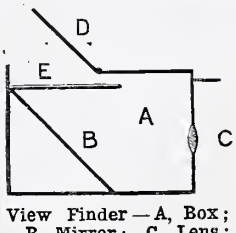
**Saw Hammers.**—A. C. R. (*Cardiff*).—It is a pleasure to me to give a description of tools required for saw hammering. I have given rough sketches of the three hammers and anvil used for the purpose. Fig. 1 represents the long cross-face hammer The face parallel with the handle is the long face, and the other the cross face. The faces are at right angles one to the other, so that the operator may strike blows that will be lengthways in one direction, as in Fig. 5 (L), and by turning the other face, as in Fig. 5, at B. Both faces of this hammer are rounded across the width and a little in the length. The amount of roundness regulates the hammer marks. The roundness of the faces of this hammer should not be so much as that in a hammer used for hammering saws after they have been ground, so that the marks may not be so plainly seen or be so deep in the plate. Fig. 2 represents a twisted



**Saw Hammers and Anvil.**

face hammer which is used for straightening saws and hammering plates that are thick, and long, and of greater diameter. The reason of this hammer being used on long and stout plates is that when a man is hammering a short saw, or one the diameter of which is not very great, he can stand close to the part he is hammering, and bend his elbow and see his work. When a long plate is to be hammered the end has to be held with the left hand, and being far from the anvil the twisted face hammer has to be used; then the operator can reach his arm straight out to reach his work, and by turning the twist hammer over he can vary the direction of the blow as with the long cross-face hammer. It will be understood that these hammers are used for straightening the plate. Fig. 3 represents a dog-head hammer, the face of which is rounded. This hammer is used to equalise the tension, as a blow struck with the dog-head will have equal effect Fig. 4 represents the anvil on which the saws are to be hammered, the face of which should be hard and slightly convex, so that the plate may have a solid bearing on the anvil. If the plate does not lay dead or solid on the anvil, the blow from the hammer will indent the plate, and the blows will not have their desired effect. I might say that, as a rule, the cross-faced and the dog-head hammers are the only hammers required outside of the smithy, or works where the saws are being made, and that the average weight of these hammers is about 3 lbs. The blows delivered should be regulated according to the thickness of the plate.—A R.

**View Finder.**—T. M. (*Liverpool*).—There are several kinds of view finders: those attached to the camera and forming part of it, and those entirely separate. The simplest kind is a double concave lens, mounted in a frame with an oblong opening of the same proportions as the plates to be used. This is either held in the hand or fixed on the top of the camera; the view will be seen in miniature in looking through it. Another is practically a small camera with the view reflected on the ground glass of the same proportion as the plate used, and may be carried as separate instruments or attached to the camera as in the usual hand cameras. The best is when two lenses of equal foci are used, as in the artist's camera, which is neither more nor less than a double camera, one for viewing the image, and the other for taking it. A useful finder may be made of a small box about 3 in. long, 2 in. wide, and 2 in. deep, with a simple double convex lens, of 2½ in. focus, arranged in the manner shown above.—D.



**View Finder—A, Box; B, Mirror; C, Lens; D, Shade; E, Ground Glass.**

**Grinding Stone.**—J. B. (*Castle Eden*).—You can procure a stone from John Dove & Co., St. Nicholas'

Buildings, Newcastle-on-Tyne. You must give them the size and say what you want it for. As it will most likely be a small one, they may not have it in stock, but will be able to get one for you. Do you think a stone will be suitable for razors? I should think a buff wheel—that is, a wooden wheel covered with leather on the edge, and sprinkled with fine emery—would be more suitable.—M.

**Slate Slab.**—G. A. W. (*Holloway*).—Draw a line on the slab at both sides where you wish to cut it, then take a joiner's tenon saw, about 12 in. long, and saw to the line. You must be careful to start the saw square, and have the slab firmly fixed. As 6 ft. is rather a long cut, you may have to sharpen the saw before you get through; but you will find it cut very well. I have sawn several in this manner. —M.

**Finishing Stove Grate.**—DOGIREM.—There is no method by which you can finish an ordinary mantel sham in the manner referred to, except by first grinding and glazing. You can, however, improve it in the following manner: Go carefully over the whole surface, and file level all projections: then take a piece of sandstone with a level face, and scour the whole surface, using circular strokes, till you get a fairly smooth surface, and finish with emery-powder and water, laid on with a level piece of wood; clean off and dry, and give a coat of paint. When the paint is quite dry, rub down with fine glass-paper stretched on a piece of board, and keep on painting and rubbing down till you get a satisfactory surface, when you can finish in any colour you wish. The paint should be of the best quality, and if you are not able to judge the quality of the ingredients yourself, you had best get a practical painter to mix it for you, telling him for what purpose you require it; as although you may know what ingredients to mix, if you cannot judge between good and inferior materials, your work may crack or blister. You will find a good deal of information on painting in Vol. I. of WORK, which, if you have not read, I should advise you to procure.—M.

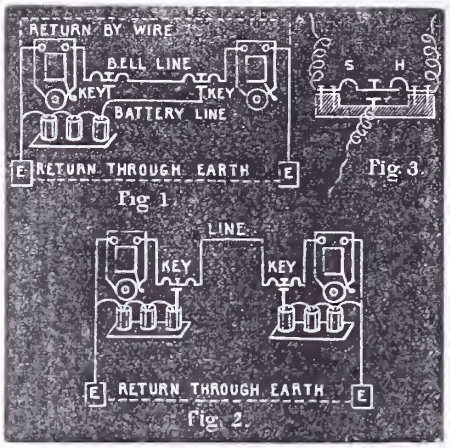
**Model Electric Lights.**—W. G. B. (*Wolverhampton*).—The series of articles on "Model Electric Lights" appeared in Nos. 76, 82, 89, 92, 94, 97, 99, 101, and 104 nine numbers; the whole set can be obtained post free from Messrs. Cassell & Co. for 1s. 1½d., or through your newsagent at the usual price of 1d. per number. In ordering from the office, always enclose an extra halfpenny stamp for each number, to cover postage; thus four numbers will cost 6d. This series of articles covers the whole ground of electric lighting likely to be taken up by amateurs. The first two treat of the principles governing electric lighting; the third gives instruction on lighting by battery power; the next four give detailed instructions for making four types of dynamos; the next deals with accumulators; and the last gives illustrations of the fittings required in an installation.—G. E. B.

**Electric Light Battery.**—G. J. S. H. (*Coventry*). —Always mix sulphuric acid with water by adding the acid *to* the water in a thin stream. If you do the contrary, and add water to the acid, the mixture will boil and spurt some of the hot fluid over the sides of the vessel. This will scald the skin if dropped on it, and will also destroy clothing. First make a solution of 3 ozs. of chromic acid in one pint of water, and add 3 fluid ozs. or a wineglassful of sulphuric acid *to* this mixture. If the connecting strips of copper are the thickness of two sheets of writing-paper, and half an inch in width, they will convey all the current you will get from four cells. The shape of the lamp is of very little consequence. A far more important factor, and the probable cause of failure, is the resistance of the carbon filament in the bulb. A lamp to be worked with four chromic acid cells must be an 8-volt lamp, as this represents the right resistance of the carbon filament. If a 6-volt lamp is used, it will probably burn up with a flash. If a lamp of 9 or 10 volts is used, it will not light at all, because the resistance of the carbon will be too great. If the filament is broken you cannot get a light from it.—G. E. B.

**Electric Light Dynamo.**—OSCAMAW (*Battersea*).—Get Nos. 92, 94, 97, and 99, back numbers of WORK, obtainable for 4d. from a newsagent, or for 6d. direct from the office. In these you will find full illustrated details of four different types of electric light dynamos. To get at the horse-power required to drive any of these, multiply the ampères by the volts, and divide 746 by the product. On p. 614, in No. 92, the No. 2 Siemens may be driven by a ¼-h.p. engine. In No. 97, p. 726, the No. 1 Gramme will serve your purpose. In No. 99, on p. 758, either the No. 2 Manchester or Simplex will come nearest to your requirements. If you take the Manchester type, kindly note that in the diagram 59, on p. 757, there is a slight error. The wire should be shown at the back of the core on the right, going from right to left instead of from left to right. As you are an engineer, you will understand how to make a dynamo by aid of these articles, which were written for amateurs.—G. E. B.

**Design of Small Dynamo.**—T. E. W. FIX.—I have not seen such a machine as that shown in your sketch, or cannot say what power you may expect from it, but should surmise that the results obtained from it as a dynamo would be equal to those got from it as a motor—that is, "very faint" indeed. Why waste time on such an unbeard-of type when good castings of tried machines can be had at low prices? You will find full information on dynamo making in Nos. 92, 97, and 99 of WORK, and will find therein some designs of four useful types.—G. E. B.

**Electric Bell Lines.**—J. M. (*Derby*).—You cannot ring two bells at two opposite stations with one battery working through a single wire. There must be a return wire on the circuit of each bell. Two bells can be rung with current from one battery if two wires and an earth connection be made, or three wires are employed together with special automatic switches or keys, as shown in the annexed diagram; or the two bells may be rung over a single line and earth, if special keys and two batteries are employed as shown in the second diagram. A diagram of the key employed in these arrangements is shown at Fig. 3. It may be made out of a few scraps of spring brass or German



Electric Bell Lines. **Fig. 1.—Diagram of two Electric Bells and one Battery, showing how to work the Bells through three Line Wires, or through two Line Wires and an Earth Return. Fig. 2.—Diagram of two Electric Bells and two Batteries, showing how to work the Bells through one Line Wire and one Earth Return. Fig. 3.—Sectional Diagram of Key employed in the above Electric Bell Systems.**

silver, bent to the form shown on the diagram, and fastened by screws to a wood base. All points of contact should be guarded with platinum. When the key is at rest, the long spring, S, is in contact with the hook, H. When the key is depressed the spring, S, comes into contact with the T-shaped piece below it, and thus connects the battery with the bell we desire to ring. When the key is at rest the home bell can be rung from the distant station, and thus a system of call and answer can be established. This system is more fully explained by me in "Electric Bells, and all about them."—G. E. B.

**Shield and Monogram.**—F. C. (*Belfast*).—Here is the shield and monogram you desire for fret cutting. To make the design a little more complete, some ornament has been introduced suitable for

J. D. B. Monogram for Fret Cutting.

metal or wood-work. Are you now convinced that we don't "think less of correspondents who live in 'Ould Ireland' than of English and Scotch ones?"

**Hour Globes.**—G. H. (*Leith*).—I do not know of any maker, and have been trying to find an importer who makes a speciality of them, but cannot do so; and I can only advise you to try the tool shops: say Haswell & Sons, 49, Spencer Street, Clerkenwell; or Grimshaw & Co., Goswell Road, Clerkenwell. Either of these, I feel sure, will supply you if you will give them the size, etc., you require. —A. B. C.

**Ploughs.**—F. W. G. (*Glasgow*).—I am very sorry if I have given the wrong address of the maker of ploughs, but the man I named had his place of business there when I was an apprentice in Glasgow, and I have ordered ploughs from him not *very* many years ago. In Glasgow you should not have much difficulty in getting what you want; any cabinet-maker can make them. But if you write to George Royle & Sons, Paternoster Row, London, you will get as many ploughs as you care to buy.—G. C.

**Band-Saw.**—AGRICOLA.—You say that you intend to fit up a band-saw. Do you mean a band-sawing machine? You should have stated the kind of work you intend to do with it, and by what power you intend to drive it. If by hand, my advice to you is to abandon all thoughts of fitting up such a machine, unless it is to do particularly light work. But if you have other than hand power to drive it, the machine may be very useful to you, and I hope you will succeed in your undertaking. To secure the satisfactory working of a band-saw, the pulleys or wheels over which the saw runs should be light, with consistent strength. The top wheel should be, say, one-third lighter than the bottom wheel. This is to prevent the top wheel overrunning the bottom wheel, and to lessen the breakage of saws. The wheels should be covered with indiarubber, to form an elastic bed for the saw. The top wheel should be so arranged that it may be raised or lowered so as to take saws of different lengths. There should also be an arrangement for canting the top wheel, so that the saw may be made to run on any part of its circumference. The last-named arrangement is of great advantage. Sometimes a saw may be shorter on the back edge than on the tooth edge, or *vice versâ*, when the strain will be greatest on the shortest edge; consequently, the saw soon breaks. By canting the top wheel the strain may be equalised on the width of the saw, and to some extent prevent breakage. The frame of your machine should be sufficiently strong to prevent vibration. The diameter of saw wheels should not be less than 24 in. Saws worked on wheels less in diameter as a rule do not give satisfaction. At the back of the saw, just above the cut and below the table, there should be a revolving disc to receive the back thrust. Be sure not to let the discs get deeply cut or grooved, or you will get frequent breakage of saws. Just above the cut and below the table there should be wooden guides on either side of the saw, to guide it as it enters and leaves the wood which is being sawn. In reference to joining a band-saw, except by brazing, there is a method, but it is not to be relied upon. In one end of the saw make two tongues, and in the other end make two corresponding openings; introduce the tongues into the openings, then press the ends together laterally, so as to cause the snugs on the tongues to hook on the bevelled edges in the openings. When the ends are in this position it will require a good strain lengthways to separate them. If you wish to disconnect the ends of the saw, separate the hooked and bevelled edges by applying lateral pressure, and at the same time draw the ends apart in the opposite direction. The only reliable way of joining a band-saw is to braze it, which process I presume you are acquainted with; if not, write again, or on any other point you wish made clear to you, and I will endeavour to help you. I might say that if you have not got Vol. I. of WORK, you can get it ready bound for 7s. 6d., wherein you will get some valuable information on saw repairing.—A. R.

**Gold Blocking.**—N. (*Finsbury Park*).—To remove gold blocking from leather may be done by washing carefully with paste water. If the leather is morocco or other grained leather, a clothes-brush may be used. Wash and brush over the gilded parts. Some parts will be more difficult to remove than others, but a little care will accomplish it. You will have to varnish the leather over with shellac varnish, which will make it look fresh again.—G. C.

**Phonograph.**—W. R. P. (*Hampstead*).—I cannot make out much from the sketch of your mouth-piece for above, so cannot tell you whether you have made it right. The cylinder of blotting-paper and candle-grease may be all right as an original dodge, but I do not wonder if you cannot get good results. Look up back numbers, and try something which has been already tried by others.—W. D.

**What Emery Wheels are Made of.**—T. P. (*St. Leonards*).—Made of an infinite variety of compounds, such as gum arabic, shellac, glue, bitumen, etc., to bind the particles together. Other kinds depend upon vitrification at high temperatures for binding the grains of emery. Vulcanite and tanite are also used, and these wheels are perhaps the safest from the danger of bursting. Every manufacturer has his own particular methods, which are not intended to be known. A simple emery grinder for an unusual shape, such as the inside of paring gouges, can be easily made by turning up a piece of wood to the correct sweep or sweeps to fit the inside of the gouges; then glue it quickly all over, and roll it in emery-powder. With

this the gouges can be ground in the lathe by dipping them constantly in water, to prevent overheating.—F. A. M.

**Work Volume.**—B. H. H. (*New Cross*).—Each year's weekly numbers of WORK are sold, bound in a cloth volume, price 7s. 6d. These and No. 4 of the "Popular Educator" are obtainable of Messrs. Cassell & Co., Limited, London, E.C., or of any bookseller.

**Rubber Stamps.**— COOKE.— Full instructions for making rubber stamps are given in Vol. I. of WORK, Nos. 38 and 40, pp. 594 and 630.—QUI VIVE.

**Stringing the Zither.**—H. R. (*Blackpool*).—Addresses of writers cannot be disclosed. Any stamped and sealed letter shall be forwarded.—ED.

**Rubber Foot.**—E. B. (*Dartmouth*).—I have too much sympathy with you in your affliction to willingly throw cold water on your proposals in this connection, but I am obliged to say that some of your suggestions are impracticable. (1) The sample of rubber sent is a good sample of vulcanised sheet rubber, but cannot be worked up again by you with advantage. (2) Solutions of rubber contain too little rubber to be of any use for your purpose. (3) Carving from a solid block offers a better chance of success, the only tool required being a sharp knife with a somewhat rough edge, moistened frequently with cold water. (4) Home-made vulcanisers would not suit the work, and a suitable one would be too expensive for use to recommend you to purchase one. "Rubber sponge" can be purchased at about 12s. per lb., and is very light; but I do not think it would be found elastic enough for you. May I suggest an alternative? If so, I would say, try cork instead of rubber. It is light, elastic enough for your purpose, and very easy to work—a knife, a half round bastard-cut file, and a sheet of glass-paper, being all that are required; it is also cheap. If thought desirable, a pad composed of, say, ten thicknesses of the sheet rubber of which you send a sample, might be placed between the wood and cork composing the foot. This would be even better if formed into a wedge, of which the thick end would be placed at the heel and the thin end at the toe end of the wooden part of the foot. On the whole, however, I would advise you to dispense entirely with indiarubber, and use cork as freely as possible.—QUI VIVE.

**Printers' Ink.**—A READER OF "WORK."—Printers' ink is not adapted for use with rubber stamps, which it would quickly spoil.—QUI VIVE.

**Induction Coils.**—T. E. W. FIX.—Dyer's book on "Intensity Coils" gives a few experiments to be performed with an induction coil and vacuum tubes; but I do not know of any book exclusively devoted to the subject.—G. E. B.

**Induction Coil.**—W. G. (*Long Lane, E.C.*).—The core should be made of iron wires annealed soft, and dipped in hot melted paraffin wax, to insulate the wires from each other. If for a small spark coil, this core may be enveloped in two or three folds of paraffined paper, and the primary wire wound on this direct. If for a medical coil with sliding regulating tube, the core must be fixed in the body of a bobbin, the tube made to slide over the core, and the primary wound on over the body of the bobbin. In the former case the paraffined paper insulates the wire from the core; in the latter case the body of the bobbin is the insulator. The wire must be insulated from the core. The quantity of silk-covered wire to be used in the primary must depend upon the size of the coil and its intended use. Just tell me the length of spark you wish to get from your coil, and I shall have pleasure in giving you dimensions, length, and size of wire, and other particulars. A wire goes from one terminal to the foot of break spring, and one end of the primary is connected to the break pillar. The ends of the secondary wire go to the handles. For further particulars, see my articles on "Induction Coils" when they appear in WORK. The battery of Leclanchè cells will work a coil giving an inch spark or more.—G. E. B.

**Castings of Dynamo.**—R. T. (*Paisley*).—Castings for the small Siemens dynamo, shown on p. 644, Vol. II., of WORK, can always be obtained from Mr. S. Bottone. The castings may not be as exactly as shown at Fig. 16 on that page, but will serve the same purpose. I think Mr. Bottone has introduced improvements favourable to the amateur since the sketches for those drawings were made. The castings sold by Mr. G. Bowron, Praed Street, London, for the same class of dynamo, differ in form from any of those shown on the page above mentioned, but may still be regarded as Siemens' dynamo castings. If you write to either of those gentlemen, they will send price lists.—G. E. B.

**Astronomical Telescope.**—A. G. (*Newcastle-on-Tyne*).—There seems, as you say, a mystery about telescope making; but it is only because the average man is quite ignorant of the art. The mystery begins to disappear as you get an acquaintance with the subject. The telescope you speak of as costing £5 would not show you planetary and lunar detail as they are shown in the average popular astronomy. Those engravings are carefully and exquisitely drawn by observers who have the use of the most powerful instruments. I tell you this because too often a would-be astronomer, fired with a desire to see for himself wonderful lunar and planetary pictures, full of the exquisitely delicate detail such as he sees depicted in the pages of text-books, pays £5 down for a popular telescope, and then is so grievously disappointed at the result of his star-gazing, that he gives up astronomy altogether. Yet a great deal that is wonderful and beautiful can be seen with a small glass, when you learn how to use its power to proper advantage; and even if this were not so, I shall show you that there is no reason why you should not finally possess a very powerful instrument. You have discovered the great obstacle to the possession of an astronomical telescope when you say that it is difficult for a workman to obtain one "without going to a very great expense." Now, there are two reasons why a good astronomical telescope is so very expensive. One reason is that the chief item in the production of a large telescope is the cost of the skilled labour required to prepare the lenses; and from this the other reason follows naturally, because, the instruments being so dear, there is a comparatively small demand for them. Telescopes are of two kinds—*refracting* and *reflecting*. The reflecting telescope is seldom seen outside the astronomical observatory. It is comparatively easy to make, and, with one or two exceptions, all the great reflecting telescope makers have begun as amateurs. But this is not the case with the refracting telescope, where four or more surfaces have to be ground and polished instead of one, and where many severe obstacles to perfection have to be overcome. It is well within your power to make a reflecting telescope, *grinding and polishing your own lenses for it*; but if you want to make a refracting telescope, you will have to buy the lenses ready made. The outside cost of the rough glass for the chief mirror of a 9 in. *reflector*—that is, a reflector with a mirror 9 in. in diameter—would be about 5s.; the market price of the finished mirror—*without any*

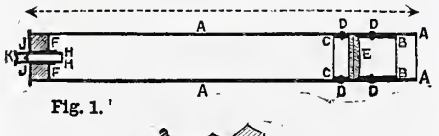


Fig. 1.

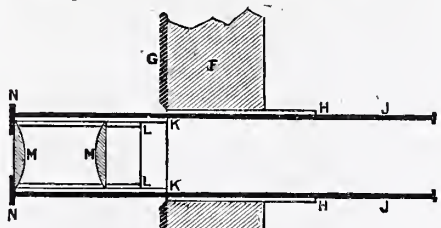

Fig. 2.

**Astronomical Telescope. Fig. 1.—Diagram for Refractor. Fig. 2.—Diagram of Eye-Piece.**

*mounting*—is, at a first-class optician's, about fifteen guineas. The difference in the price is the payment for skilled hand labour, no tools, properly so called, being necessary for its manufacture. But the cost of the rough glass for a lens of similar diameter for a *refractor* is about £25, and the market price of the finished lens, without any mounting but its brass cell, is £200. Here, also, the difference is in skilled hand labour. But you may see how much easier it is to make a reflecting telescope than it is to make a refractor. If you decide to make the reflector, you must watch the replies I am giving elsewhere in "Shop." You will get guidance there, and you must come to the Editor when you get into any difficulty. But if you decide to make a small refractor to go on with, above is a diagram to work from. I assume that you will purchase a 2½ in. achromatic object lens of, say, 36 in. focus. The price of this will vary from 30s. or less to £3, according to its quality. Then: A A A A is a piece of stout drawn brass tubing; B B and C C are rings cut from a smaller size tube, and fitting accurately inside A A, and turned or filed quite true at the edges. If they be true, and are stood on edge on a flat surface, the sides will be at right angles with that surface. The smaller ring, C C, should be slipped in, and fastened with the small screws, D, D. This forms a ledge for the support of the lens, E, which is then placed in position, and secured by sliding and screwing into position the ring, B B. At the other end of A is F F, a disc of wood turned to fit inside A, and pierced with a central hole, which receives a piece of smaller tubing, H H, which carries the eye-piece, as in Fig. 2. F F may be faced with a disc of brass, G, for appearance sake, if it be intended to polish the finished instrument. Required: Two plano-convex lenses, ⅞ in. in diameter and 1 in. in focus. Cost, about 1s. each; tubing, K K, into which the lenses will exactly fit. Fix them as shown by means of the smaller size tubing, L L. The lenses will require to be two-thirds of their focal (not joint focal) length apart, in this case two-thirds of an inch. The focal lens is kept in place by a pierced brass disc, N, soldered or screwed to K. It will be observed that the finished eye-piece, K N, slides into the longer tube, J, which in turn slides to and fro in tube H, fixed to F. By this means the eye-piece can be pushed towards or pulled from the object-glass to get the proper definition. This eye-piece is called the Ramsden eye-piece. The completed telescope will require to be mounted on a firm ordinary telescope stand, which I have not space left to describe here. It will be seen that I have chosen the simplest possible form of mounting—a form which entirely obviates the necessity for screw cutting. There are other methods and other eye-pieces, but this form contains all the essentials. The magnifying power could be increased by using an eye-piece made on the same principle, but with lenses of shorter focus. Finally, the cost of the whole instrument could be lessened by the use of an ordinary uncorrected single lens for the object-glass. Such a lens would cost about 2s. 6d. or 3s. 6d., but, of course, the object under examination would not appear clearly defined or free from colour.—E. A. F.

**Vulcanite Tubing.**—C. C. (*Clapham Road*).—This can be obtained of most of the manufacturers of rubber goods, of which there are several in London, and can be united by means of a thick solution of rubber in mineral naphtha or bisulphide of carbon, or by a solution of shellac in methylated spirit. Vulcanite can also be moulded when softened just sufficiently by gentle heat to enable it to take the requisite shape under considerable pressure.—QUI VIVE.

**Staining Xylonite.**—W. J. H. (*Reading*).—An address where xylonite can be bought was given in "Shop," p. 556 (No. 139). Xylonite, celluloid, parkesine, or ivorine, are practically the same, and mostly made in France and America. I am using some now which bears the impress, Celluloid Manufacturing Company, U.S.A., which, being white and used mostly for musical instruments, is obtained from wholesale dealers in musical fittings. Much information and useful hints on xylonite will be found in WORK, No. 101, p. 787, "Xylonite: its Nature and Use;" and in No. 113, p. 130, "Xylonite as a Material for Fret Sawyers." I have found the aniline dyes as sold by chemists and drysalters in packets and tubes a good staining medium. The chemical stains as used for ivory are in most cases impracticable in use, and should in all cases be used with caution, as owing to the acids and camphor used in the manufacture of xylonite, an opposite effect to that required might be given. As the material can be bought ready dyed in self and fancy colours, also in imitation of pearl, marble, and tortoiseshell, etc., you will see there is little need to use the stains oneself, unless you, as a stick-maker, require to finish your stick handles, engraved, or incised and coloured, as sometimes seen. In that case, the pattern is mostly incised and the inner portion stained; the incisions are then useful, as they prevent the stains from running. Pigments or oil colours will not do, as in the process of polishing by means of pumice powder, or tripoli and benzoline, they would be rubbed off again. After the polishing the incisions are generally finished gilt, which gives a pretty finish.—LIFEBOAT.

**Puzzle Purses.**—A POLE.—It would not be worth your while to follow this up. The possible profits to be derived from your idea are of a most slender kind.

**Canoe.**—B. B. (*No Address*).—If you have only a few joiners' tools it is hardly likely that you will succeed in building a canoe for that "large pond" near your house. You had better be less ambitious, and in your desire to be mechanical, make some experiments first with a small boat or other model.—ED.

**Ship Models.**—R. J. B. (*Whitby*).—It would occupy too much valuable space to give illustrations of the vessels you ask for as models; but any definite question you may ask shall be answered.

**Voltaic Battery.**—F. M. (*Thornton*).—In the first place, it would be better to test your cell currents by an *ammeter:* the ammonium sulphate test is rather delicate, and applied to a cell of so low a voltage as the Leclauché, may mislead anyone not accustomed to its use. In your "Fuller's Patent" cell you seem to have omitted the mercury, which should be placed in the bottom of the cell. You should remember that the zinc element is that which is used up—burnt, as it were—and also that the best of commercial cast zinc is impure, and therefore *local currents* are set up when the circuit is broken. To prevent this, amalgamation is resorted to, and the mercury in the "Fuller" cell preserves the zinc from local currents, because it keeps the zinc amalgamated. You seem to take a great interest in this matter. I should advise you to study the polarisation of low-power cells, with zinc and copper couples, with a view to arrange a *perfectly constant* battery. If you write again, I shall be glad to give any advice I can.—F. C.

**Ventilating Tunnels.**—D. D. (*Edinburgh*).—Your proposal is quite practicable, but unfortunately it is not new. It was proposed a good many years since. There are several practical difficulties in the way of its adoption, and unless a very large tube were used, it would only be suitable on lines worked by engines which exhaust into the tender or into a condenser. Your experiment does not include the effect of the powerful exhaust blast from a locomotive chimney.—F. C.

**Iron-work Book.**—J. S. W. (*West Bromwich*).—Working drawings are rather difficult matters to treat in a book. A good many are given in Humber's "Treatise on Iron Bridges," but that is a very costly work. There is a very simply written book showing how to calculate and design the details of iron bridges from which to make working drawings. Its title is "Materials and Construction," by F. Campin, published by Messrs. Lockwood & Co., London.—F. C.

**Delta Metal.**—IGNORANT.—I cannot answer your question, for the simple reason that Delta metal is a patented invention, and beyond the fact that certain materials are used in its composition, the general public know nothing of Mr. Dick's methods, which are the result of many years' experiments. The methods and proportions can be so greatly varied that Delta metal of any required grade, both cast and forged, is obtainable. You could not make it, even if you posscssed the secret of its preparation, because it is patented. If you write to the Delta Metal Company, Limited, 110, Cannon Street, E.C., and ask for their pamphlet on "Delta Metal," you will obtain from it nearly all the information available on this useful alloy.—J.

**Polishing and Upholstering Chairs.**—A. T. (*Canonbury, N.*).—Much has been given in the present volume on the subject of French polishing. Consult "Shop" and the indexes. You omit to tell us how you were going to buy the frames, whether in the *white*—*i.e.*, unstained or unpolished—or in the natural woods—*i.e.*, walnut or mahogany. Presuming that you buy them in the natural woods, ample instructions have been already given; on the other hand, if in the white, it will be necessary to first stain them, walnut or mahogany being the usual finish. In that case, I cannot do better than refer you to a reply given in "Shop" ("Staining and Polishing Cheap Furniture"), p. 476, No. 134. For a walnut stain, refer to "Means, Modes, and Methods," p. 439, No. 132. As regards the upholstering, you have set yourself a difficult task in desiring to take your first lesson on saddle-bag upholstery. Without in any way desiring to dishearten you, I should have thought it best to practise first at plain work. To give only a fair idea of how it is done, the materials required, and tools to use, would take up at least a whole page of WORK. You would do well to procure the second volume of WORK, or at least Nos. 78 and 100, in which will be found articles on "An Armchair: How to Make the Frame and Upholster it." I need hardly remind you that all necessary staining and polishing are done previous to upholstering.—LIFEBOAT.

**Painting and Graining.**—W. W. (*Nelson*).—A useful little manual for amateurs can be obtained from Brodie & Middleton, Long Acre, London, price 2s. Vol. I. of WORK contains much useful information on the first-named branch, and the present volume will eventually contain the required knowledge for studying graining. If you haven't Vol. I., *get it quickly*, its value will increase with each issue. As a practical worker, acquainted with all classes of technical literature, I look upon it as a wonderful collection of information and instruction, worth its cost a dozen times over.—F. P.

**Potash Solution.**—P. P. (*London*).—To make a saturated solution of any salt, the salt, as chlorate of potash, is added to and stirred up with water, until the water will dissolve no more. Hot water will dissolve more of most salts than cold; thus, boiling water will dissolve ten times as much chlorate of potash as cold will, and a convenient way to make a saturated solution is to dissolve as much of the salt as you can in boiling water. On cooling, the excess of salt will crystallise out, leaving a cold saturated solution.—F. B. C.

**Varnishes.**—KING BRUCE.—You do justice to your *nom de plume*, and we hope will now attain the desired success. I must confess your requirements of a varnish "which must not soften on exposure to dampness nor blister with heat," appear to the writer as two points which could scarcely be guaranteed by the most experienced of varnish makers. According to my promise in a previous answer, I have, however, consulted an authority more experienced in making varnishes than the undersigned, and append herewith the advice and recipe. With the fullest confidence in the source from which it is obtained, I commend it to you: Stained Varnish: 2 lbs. gum benzoin, 2 lbs. orange shellac, 1 gallon methylated spirits; put all in a stone vessel, and shake them occasionally until dissolved; then stand in an open vessel for a few days before using, and also strain through a fine strainer. The desired colours can be obtained by adding aniline colours to the desired shade. This varnish should be used in a warm atmosphere. For making the "white" varnish, use white shellac instead of the orange. The gum above specified is the real basis of the varnish; the shellac may be varied from 50 to 100 per cent.; but this I would not advise you to experiment with until you have succeeded with the proportions given and the colours you require for the various kinds of pipes. For the gums, etc., write to Mathieson Bros., Ardrossan, N.B., and watch the advertisement columns of WORK.—F. P.

**Wire Bird-Cages.** — RUFUS.—An article has already appeared on making wire bird-cages. (See Nos. 54 and 80 of WORK.)

**Wire-Work (Bending Tube for Surrounding).**—R. J. (*Burdett Road, E.*).—If you want to bend only one or two tubes for surrounding wire-work, the following method will answer: Select a tube composed of as thin metal as compatible with the desired strength, and secure it to the bench by means of small screwed blocks on each side, touching, but in no other way being connected to it. Pass a stick, as tight-fitting as possible, along the interior of the tube. Lever the tube by hammering a chisel through its upper surface, taking care that each cut is in a direct line with the previous one. When cut its whole length, withdraw the stick. Secure a hard wood or metal block to the bench, the outline of it corresponding to the desired curve to be given to the tube. If the latter is not too strong, you can bend it round the block by the assistance of your hands only; but it may chance that it will need to be hammered, which should be done with some soft material intervening, to prevent bruises. Begin bending at the middle; or if the tube is too strong for this, staple one end against the block, further securing it with an end nail, and then progress with it. Use nippers to squeeze the tube, thus split and bent, over the wire-work.—J. S.

**Cabinet Design.**—SCHEMER.—Thanks; but your designs are hardly up to WORK standard.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**False Hand.**—INDIARUBBER writes:—"I venture to ask if any reader of WORK could give the address of an indiarubber firm where I could get a false hand made, as I have had the misfortune to lose part of my hand and three fingers. If I made a model in plaster, could I get it cast in indiarubber with hollow fingers, to be as light as possible, but at the same time stiff—much the same as indiarubber dolls are made?"

**Asbestos.**—YENWILL writes:—"Will any reader of WORK kindly say if asbestos can be woven into a cloth or kind of tape without any foreign substance being mixed with it? I have a specimen of asbestos-woven cloth, but it appears to have a mixture of some sort, and I wish to get some without if I can. Also what is about the price of raw material?"

**Double Flageolet.**—S. (*Bristol*) writes:—"Can any of your readers inform me where I can procure a double flagcolet, and what would be the price, or give me information as to the making of one?"

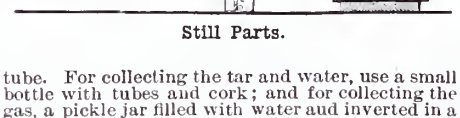
**Whip Handles.**—E. E. S. (*Bickington*) writes:—"Where could I get leather handles for driving whips? I have asked in shops about here, but they can't tell me. I know they are to be had, and I should say probably at Birmingham."

**Paper-Making.**—J. W. (*Plumstead*) writes:—"I shall be glad if any reader could give me information as to addresses of paper-mills, or aid me to find out prices paid for rags, bones, etc."

**Breeding Cage.**—GAMMA writes:—"I am about to make a breeding cage, introducing some fret-work and painted glass; the size I proposed making it to be 20 in. by 17 in. by 10 in. My idea was to make three of the sides of ¼ in. wood, with fret-cut windows, having tracery something in the cathedral window style; the windows to be afterwards glazed and painted like stained glass. Could any of your correspondents suggest a design for the cage—something in the Gothic style?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Still for Wood.**—H. B. S. (*Liverpool*) writes, in reply to LONDON (see p. 542, No. 138):—"If you want to distil the wood on an experimental scale, get a piece of iron pipe about a foot long and about an inch wide, with a screw plug to fit one end; to the other end fit a cork with hole bored, and bent glass



Still Parts.

tube. For collecting the tar and water, use a small bottle with tubes and cork; and for collecting the gas, a pickle jar filled with water and inverted in a tin or other bowl partly filled with water: heat the iron tube in a fire or over a burner up to about 2 in. from the cork. On the large scale wood is distilled in retorts similar to those used in the manufacture of coal gas, made of cast iron, and heated in a furnace suitably constructed."

**Cardboard Models.**—A. H. (*Woolwich*) writes, in reply to C. W. S. (*Northallerton*) (see p. 574, No. 140):—"You would be able to obtain them from Clarke & Sons, Hatton Garden, London, or by ordering them from any large newsagent in your town."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—CELL; J. B. (*Dalton-in-Furness*); B. J. (*King's Lynn*); B. R. (*Sandbach*); W. H. (*Brinscall*); LUDO VICUS; G. (*Sydenham*); T. W. (*Kendal*); R. W. (*Bold Heath*); W. B. (*North Woolwich*); BEGINNER; P. L. (*Selly Oak*); J. A. B. (*Camberwell*); W. S. (*Stourbridge*); R. C. (*Battersea*); E. H. J. (*Bishopston*); F. H. (*Battersea*); A. M. B. (*Dublin*); OLD BOAT; E. A. (*Sheffield*); F. H. (*Finchley*); R. S. (*London, E.C.*); F. S. (*Leek*); S. A. (*York*); N. M. (*Sheffield*); G. C. (*Stratford-on-Avon*); M. F. (*Oldham*); P. H. (*Bristol*); HOT WATER; M. W. (*Manchester*); P. D. (*Lincoln*); S. R. (*Newry*); T. W. B. (*Faversham*); W. H. E. (*Crewe*); H. M. (*Manchester*); EDNIFRA; C. W. L. (*Newcastle-on-Tyne*); W. W. (*Stalcybridge*); W. H. (*Egham*); GAS LIGHTER; RALPHO; J. W. & CO. (*London, W.C.*); LEISURE TIME WORKER; W. T. L. ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

# WORK

## An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 149.] SATURDAY, JANUARY 23, 1892. [PRICE ONE PENNY.

### A SMALL PORTABLE FORGE FOR AMATEURS' WORKSHOPS.

BY "CYCLOPS."

THERE are many operations required to be performed in an amateur's workshop which necessitate the use of a smith's hearth, and where this useful appliance is not possessed by the workman it becomes necessary to put work out, entailing loss of both time and money.

It is my purpose in this article to describe a simple smith's hearth or forge, which has two distinct advantages. First, of being easily made by the average amateur iron-worker; and, secondly, of great portability. The latter is of considerable moment in the amateur's workshop, which is generally rather cramped. The appliance consists of a wrought-iron frame, on the top of which is the tray, or hearth proper; and underneath the hearth, the bellows and blowing arrangement for the draught. A general idea of this may be gained from a glance at Fig. 1.

*Framework, etc.*—The framework consists of four legs, A, A, A, A (Fig. 1), braced to-

Fig. 14.

Fig. 1.—Hearth complete. Fig. 2.—Front and Side Elevation of Legs. Fig. 3.—Plan and Side View of Bottom Stays. Fig. 4.—Plan and Side View of Guide-Stay for Bellows. Fig. 5.—Sheet Iron cut to form Side of Tray. Fig. 6.—Section and Under View of Bellows. Fig. 7.—Guide-Pin for Bellows. Fig. 8.—Nozzle and Bellows Connection. Fig. 9.—Spindle. Fig. 10.—Bellows Links. Fig. 11.—Bracket. Fig. 12.—Crank on end of Spindle. Fig. 13.—Lever on end of Spindle. Fig. 14.—Links and Crank Connection.

gether by the cross-stays, B, B, two above and two below the bellows. The two stays above the bellows are not shown in the drawing, being hidden by the tray, etc. They are of the same form and dimensions as the bottom pair, except at the centre, where they cross each other, one of them being cranked down to allow the other to cross it at its own level, and thus make a level bed for the hearth-tray to rest on. One of the legs A, A, A, A, is shown separately in front and side elevation in Fig. 2.

The whole of the framework is made of 1 in. by $\frac{3}{8}$ in. square iron bar, and is riveted together by $\frac{3}{4}$ in. by $\frac{7}{8}$ in., and $\frac{3}{8}$ in. by $1\frac{1}{4}$ in. iron rivets, the holes being bored to allow the rivets to fit in rather tight. The dimensions of the various members of the framework being all marked in the drawings, it will not be necessary to mention them here.

The various parts of the framework should first be forged and cut to dimensions given in drawings, and fitted against one another to make sure that they are all exact before marking out for drilling. The two cross-stays, B, B (Fig. 1), are riveted together where they cross in the centre of the frame as shown. The ring, D (Fig. 1), is placed round the outside of frame at the points where the cross-stays are riveted to the legs, and the rivets pass through the ring, D, legs, A, A, A, A, and cross-stays, B, B, binding them all securely together.

*The Hearth.*—The hearth consists of a flat, round plate of iron, which should be a good thickness to withstand the heat; or, if a little extra expense is not objected to, it might be made of thinner material and a circular fireclay brick bottom placed on it. This would make a much more serviceable job.

The hearth-plate rests on the top pair of cross-stays, and is riveted to them by four rivets, two in each stay. The circular band, I, surrounding the hearth is cut out of $\frac{3}{16}$ in. sheet iron to the plan shown at Fig. 5; the hole A is for the introduction of the air-nozzle, J, from the bellows. The band is riveted to the top of each leg by two rivets, as shown at P, P (Fig. 1), and is also riveted together at its two ends, as shown at O (Fig. 1), by four rivets. The hearth-plate before-mentioned is cut to exactly fit inside the band, I, and to rest on the top pair of cross-stays.

*Bellows Fittings.*—The bellows work next occupies our attention. It consists of a spindle of $\frac{3}{4}$ in. round iron, working in two brackets, shown at K (Fig. 1), the form of which is better shown in Fig. 11, the dimensions being marked to it. These brackets are riveted, one to each of two opposite legs, by two rivets in each as shown in Fig. 1. The spindle is shown at H (Fig. 1), and also in Fig. 9, the ends, Q, being squared to fit the small cranks, L (Fig. 1), and the long lever, M (Fig. 1). These cranks are shown in plan and elevation in Fig. 12, and the long lever in Fig. 13. As will be seen from Fig. 9, the ends of the lever are squared and screwed. The dimensions marked for the square part is $\frac{3}{4}$ in. This is, of course, for the end carrying the long lever, as well as the crank; the other end, which carries only a crank, will have the squared part only $\frac{1}{2}$ in. in length.

The cross-stay, C (Fig. 1), is simply to act as a guide to ensure the top chamber of the bellows rising and falling perpendicularly. It is secured to one pair of legs by rivets as the cross-stays are; it is made of 1 in. by $\frac{3}{8}$ in. iron bar, swelled out and bored in the centre, as shown at Fig. 4, to allow the guide-rod, F (Fig. 1), to slide easily through it. The upright guide-rod and square plate are shown in Fig. 7. The rod is of $\frac{1}{2}$ in. round iron rod, and the plate is countersunk for four screws, with which to attach it to the top board of the bellows, the rod being riveted into the square plate. The bellows, E (Fig. 1), are fastened to the frame by four stout wood screws, one through each leg. Between the legs and the centre board of bellows are placed four pieces of $\frac{1}{2}$ in. iron pipe, about 1 in. long; the four screws pass through the legs into these pieces of pipe, and are driven home into the centre-board of bellows, holding them quite securely.

The bottom chamber of the bellows is supported by four links, shown at G, G, G, G (Fig. 1).

Each end of these links is swelled out and bored (as shown in Fig. 10) at the bottom ends to fit on the round ends of two flat bars running across the bottom board of bellows (shown in Fig. 6), and at the top ends for the reception of the $\frac{3}{8}$ in. bolts, which connect them to the short crank, L (Fig. 1.) This arrangement is better seen at Fig. 14, L being the short crank, G, G the links, and Z the $\frac{3}{8}$ in. bolt and nut.

The flat bars just mentioned, and shown at Fig. 6, are made of 1 in. by $\frac{3}{8}$ in. iron bar, and are drawn out to a round section at the ends, and screwed for nuts, which keep the links in their place. They are fastened to the bellows' bottom board by three screws in each, passing through holes drilled and countersunk to receive them.

*The Bellows.*—We must now consider the construction of the bellows proper. These are composed of three circular boards of inch stuff, $14\frac{1}{2}$ in. in diameter. The middle and bottom boards are provided with valves, one in each opening upwards. These are made by drilling a hole, 2 in. in diameter, in the centre of each of the two boards. Over each of these holes is placed a flat, circular piece of leather nailed to the board at one side, so as to be free to move up and down for the passage of the air. A piece of wood is glued on the top of the leathers, to ensure dropping down flat and closing the valve when the air is within.

A wire stop, S (Fig. 6), is driven into the board, to prevent the wood valves turning completely over, in which case they would not again close when required. The top drawing in Fig. 6 shows a cross section of valves and bellows.

The middle board has a block of wood fastened to it, as shown in Fig. 6. This is for the reception of the screwed end of the pipe conveying the blast from the bellows to the hearth.

The three boards are fastened together by a piece of leather 14 in. wide, which goes all round them, and is securely nailed to their edges by 1 in. clout nails, placed in two rows, and as near together as possible. A strip of leather, 1 in. in width, is placed round the edge of each board over the leather covering, and the clout nails are driven through this and the leather covering into the boards. Before fixing the leather on to the boards, we shall have to insert four iron rings, made of $\frac{1}{4}$ in. round iron bar, $14\frac{1}{2}$ in. diameter outside, two in each chamber. These are to keep the leather stretched outward, and to ensure it forming even creases when opening and closing. The two ends of the circular band of leather covering the bellows should be joined with copper rivets and washers, such as are used for leather hose. These should be put as near together as possible.

The pipe leading the blast from the bellows to hearth is of $\frac{3}{4}$ in. iron tube, and is shown in section, with its fittings, in Fig. 8. It is screwed at the bottom into the wood block, T, and at the top into the air-nozzle, J, through the iron band encircling the hearth, with a back nut and washer to keep it secure. The air-nozzle should be of very thick wrought iron, and tapped to receive the end of the $\frac{3}{4}$ in. tube as shown.

The leather of the bellows covering should be of thorough good quality, and may be obtained at any currier's. It is scarcely likely that a piece will be obtained sufficiently large to make it in one piece, so that it will have to be joined with copper washers as described.

Our forge is now complete, and it only remains to regulate the flow of air by putting weights on the top board of bellows. Weights should also be suspended from the bottom boards sufficient to draw the lever up when pressed down. We shall now have a thoroughly substantial hearth if the above directions have been faithfully followed. Of course, the measurements may be varied to suit the maker, and it could even be made of lighter material; but, owing to the great amount of knocking about such a hearth will have to sustain, it will be best to keep as near as possible to the dimensions given.

Should any further help be required, the writer will be glad to give it through the medium of "Shop."

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

### The Feed-Pump and Governor—Conclusion.

Why Pumps will not Work—How a Feed-Pump should Not be Made—Spanners and Nuts—The Governor, Bracket, Sleeve, and Mitre-Wheels—Turning the Bolts—Fitting Arms—Throttle-Valve and Case—Adjusting Spring and Sizing Driving Pulleys—Stauffer Lubricators—Lagging of Cylinder—Making Steam Joints—Foundation of Engine—Driving Belt.

A word needs to be said as to the design of the pump. Many pumps fail, or give trouble, on account of the presence of air inside. When the plunger is drawn up this air expands, but no water rises into the barrel; when the plunger comes back the air contracts again.

Several drawings of feed-pumps have been recommended in mechanical publications, which are open to such an objection: Fig. 57 will make this quite plain. Here the plunger is much smaller than the pump-barrel, leaving a wide annular space round it; when air gets into the pump—as it is sure to do with the water—it will, of course, rise to the top, and the upper part of the barrel at *b* will be full of air, whilst any water there may be will lie at the bottom, as seen in the sketch. Now, when the plunger is raised the air will expand, and the exhaustion will be so little that it will be insufficient to raise the suction-valve and the column of water beneath it, and the consequence is the pump will not "draw." The usual remedy for this is to place a pet-cock at *a* to let out the air, but the proper course would surely be to place the passage to the delivery-valve at *a*, because then the air would be the first to leave the pump; also the superfluous space at *b* should be filled up. Turning now to our pump, it will be seen the delivery-valve is

on the highest point of the inside of the pump, so that the air may be got rid of first. If anyone wishes to know where the air comes from, let him place a glass of water under the receiver of an air-pump, when he will quickly discover it comes from the water, being held in solution at atmospheric pressure, and boiling out as soon as the pressure is diminished. The valves are arranged to have a lift of $\frac{1}{16}$ in. When a valve of this sort lifts a distance equal to a quarter of its diameter, then the annular space opened under its edge is equal to the area of the valve. By this rule the lift of the smallest valve should be $\frac{1}{64}$ more than $\frac{1}{16}$ in., but it is well to allow a small lift; in the case of the upper valve, which must of necessity be of larger diameter, there is sure to be sufficient passage, and the lift might be rather less than $\frac{1}{16}$, which will diminish the shock and noise at each closure. Water confined in a pump or pipe is so incompressible that it must be considered almost as a solid; were the plunger of the pump to meet in the middle of its stroke a solid piece of heavy metal, there would be a thump and a shock; just such a shock may be expected in a force-pump, when the plunger, having filled up the empty space left in the body of the pump after the up-stroke, meets the column of water in the feed-pipe, and drives it a few inches further on. To prevent this shock, a cushion of air is provided in an air-vessel, and, instead of mounting a separate air-vessel on the top of the valve-box, the valve-box itself is prolonged upwards a little way, so as to imprison a small quantity of air above the delivery branch, which, by its elasticity, acts like the spring of a buffer to prevent a sudden shock to the passengers.

*Spanners and Nuts.*—With Fig. 5 (page 260) are shown two double-ended spanners; the larger one has an octagonal jaw at the large end, and it is intended to fit both the piston-rod and pump plunger-glands to tighten them up. The smaller end of this same spanner is hexagonal, and is intended to fit the gland of the slide-valve rod and the union-nut on the delivery branch of the pump, as also the hexagon upon the cap of pump valve-box. The smaller spanner fits all the other nuts about the engine except one; there are two sizes of them, for screws of $\frac{1}{4}$ in. diameter and $\frac{3}{16}$ in. The nuts, if made at home, should be carefully kept to the same size; and if bought, they should be obtained, all of them, from the same firm. They would be best of steel, hardened, as also the spanners, and spring-tempered, or let down to a blue, or simply "blazed off"—that is, hardened in oil; and then, while the oil is upon them, held in the flame till the oil "flashes," and then quenched. This leaves them hard enough, yet tough. This hardening will leave them black, but they will look very well so, forming a pleasing contrast with the bright work. The spanners may be made as steel forgings by the nearest smith. Saw out a pattern of fret-wood for him to work to. File up a tin template for gauging the large one, to get it the exact size; file the small one to fit the nuts, then harden and temper them both.

We may now undertake the construction of the governor. It appears in Fig. 4 and Fig. 6, but the details are best seen in Fig. 24 (page 328). The old Watt governor, as in old engines and text-books, has six joints; this one has but two. The newer forms of governors have a spring on the spindle or shaft, and some of them scarcely look like governors at all. The form here given has something of the orthodox look without the troublesome six joints; it will work as it is, or may have springs attached if desired. The only difficulty connected with this form of construction is the tubular spindle, $3\frac{1}{2}$ in. long, $\frac{1}{4}$ in. diameter, with a $\frac{1}{8}$ in. hole through it. This may be made from a bit of round steel, bored through, and then turned true with the bore; but steel tubing of this size can be obtained.

We will begin with the main bracket by bolting it upon the angle-plate upon its side, and after boring it through with a $\frac{1}{4}$ in. drill, turn the recess in the top which holds the oil and the rounded bead on the edge. Now turn the casting round upon the angle-plate and bore the long boss, also with a $\frac{1}{4}$ in. drill, and face the end. Take the brass casting for the body or sleeve of the governor, with the two arms on it; hold it in a universal chuck, and bore it with a $\frac{1}{4}$ in. hole. Now take the steel tube and put it between the centres of the lathe to get it perfectly straight by bending; when it runs quite true, try it into the standard or body, and reduce it by turning or simply by filing till you can drive it firmly in; then it will not need the little round pin, seen at the top, for securing the two together. Now turn the outside of the body, and then reduce still further the lower half of the tube till it will turn easily in the bracket, carefully squaring up and smoothing the bottom surface of the brass body where it rests and turns upon the top of the standard.

The little mitre-wheel underneath will be the next to fix. The under-side of the hole in the bracket would be first filed up square for the wheel to work against, and then the wheel may be fixed by the pin, as shown. This pin cannot go through the middle, because of the little $\frac{1}{8}$ in. rod which slides inside the tube. The wheel may be keyed if that be thought easier, or it might be fixed with a pinching-screw. These mitre-wheels can be bought ready-made for one shilling each.

Now take the governor-balls, 1 in. in diameter; fix a bit of sheet metal into a wood chuck, and bore an inch hole in it; then cut it in two, and it will serve as a template to guide you in turning up the balls. The template should be so cut that it will give you one exact half-circle. If these balls were for ball-valves, we should have to be most particular in turning them, and it would be necessary to make a special tool, but in this case we may proceed as follows:—Chuck the balls by driving them into a recess in a hard wood chuck till very slightly more than the half diameter projects; turn the projecting part to an exact half-sphere, using the template to test it; then bore a hole in the middle of the ball, and tap it ready to screw on to the arm. When both the balls have been treated so, alter the chuck so that you can fix them in the opposite way up to the shoulder left by the turning, so that exactly the half-sphere will now be contained within the chuck; now turn the projecting portion true to the template; if the template is exactly the half circle, and you are tolerably careful, you will not be far wrong. Of course you can re-chuck the balls at different angles and reduce the error, but I think for this purpose it would be unnecessary. There should be a small hole through the back of the wood chuck to drive the balls out by, and a little screw may be made on any bit of steel held in the lathe, on which to mount the balls to polish the whole of the outside. Now take the arms on which the balls hang, centre them and turn them up, cutting the screws to fit into the balls. The shoulder against which the balls screw is a collar $\frac{1}{4}$ in. in diameter, and that is just the thickness of the joint at the other end. File the flat of the joint parallel with the arms, laying them down sideways on the face-plate to try it, and file out the slot which forms the joint in the arms of the body of the governor. The file can be passed through both arms (see Fig. 27), so that it is easy to file out these two joints and make a perfect fit. The arms of the governor carry small levers at an angle of 120° with the longer part of the arms, which short arms or levers meet in the centre, in the slot of the brass piece which forms the top of the governors, and are halved together in that slot. The shape of one of these small levers is seen projected above (Fig. 24), and the top piece with slot at Fig. 26. This little piece is pinned on to a $\frac{1}{8}$ in. steel wire, which passes down the centre of the governor and revolves with it, but can be raised up or down $\frac{3}{8}$ in., according as the balls are hanging down or flying out. Upon the lower end of this steel wire is pinned another piece of brass in which is turned a deep groove; in this groove enters the forked end of a small lever, clearly seen in Fig. 25, which lever is also shown projected above; it is secured to a piece of $\frac{1}{8}$ in. brass wire, which passes straight through the gland of the throttle-valve (see also Fig. 28). The lever might have upon it an arm, as dotted, with an adjustable weight for regulating the speed at which the governors would control the engine within small limits. But if our engine is simply required for driving a lathe, etc., in an amateur's workshop, a high degree of regularity will not be required.

The wire which controls the throttle-valve is made of brass, because, like the pump and its plunger, it would be liable to rust if it were of iron, and that would cause unnecessary friction in the stuffing-box. This stuffing-box is clearly seen in section in Fig. 25. It requires to be carefully packed and screwed up as lightly as may be, only just enough to prevent the escape of steam. It would be very easy to screw it so tight that the governor could not rise at all, and would have no control whatever over the engine.

Coming now to the throttle-valve and its case, shown separately at Fig. 28, it may be held in a universal while the oval flange is faced; then the holes for the bolt might be made through this flange, and then it could be clamped by the flange upon a face-plate, the hole inside bored out true and smooth, the screw-thread cut (gas thread) to fit the stop-valve, the shoulder faced, and the edge turned bright. It is supposed that a stop-valve would be bought, and not made. It will cost about four shillings. A $\frac{3}{8}$ in. stop-valve is large enough for this engine, and $\frac{3}{8}$ in. piping for the steam-pipe; but $\frac{1}{2}$ in. would be better for the exhaust. That being the case, it will be simpler to have both steam and exhaust $\frac{1}{2}$ in. bore, and then the stop-valve must be $\frac{1}{2}$ in. too. A $\frac{1}{2}$ in. stop-valve is shown at Fig. 4. There will be required a $\frac{1}{2}$ in. "nipple" to connect the stop-valve with the standard, since both these have female threads. A "nipple" is a short ferrule of pipe with threads on the outside; it would be screwed firmly into the standard, and the stop-valve would screw upon that. The throttle-valve case, or standard, may be mounted upon the angle-plate chuck to bore and tap the stuffing-box, which is to be done at an angle of 45° with the flange. The casting for the throttle-valve itself appears at Fig. 29. It will be

centred and turned till it will fit into the bored hole in the standard. The hole for the brass wire which carries and controls it may, perhaps, best be bored by placing the valve in position in the case or standard, and then passing the drill in through the stuffing-box and gland. Next, the governor standard would be fixed and screwed down in position, and the hole for the other end of the brass wire bored through the arm of the bracket made to sustain it, when the wire would be put through that arm and the stuffing-box of the throttle-valve standard, while the latter was placed in position on the valve-box. Thus arranged, the holes through the oval flange could be correctly marked upon the steam-chest. The stems cast on the throttle-valve to aid in turning it may now be cut off, and the hole through valve and wire drilled, and the little brass pin, seen in Fig. 28, inserted. All that is required now to complete the connection between the governor and the throttle-valve is to make the little lever which embraces the grooved piece at the bottom of the small rod which passes down the centre of the governor. Now fit the shaft in the long boss, bore the small pulley which receives the band, drive it on at one end, and turn it up in position; bore and fix the little mitre-wheel at the other end, adjusting it to gear to the correct depth, and fixing it with a key or a pin driven right through.

It must not be supposed that the throttle-valve will stop the steam without any leakage: it could not do so fitted in this way; the stop-valve will do that; but the throttle-valve will stop nearly all passage of steam, and when closed by the governor there should not be sufficient leakage to work the engine. The parts of the governor are so proportioned as to allow the engine to run at about 100 revolutions per minute. The pulley on the horizontal driving shaft is the same size as the groove in the boss of the eccentric, so that both engine and governor would run at the same rate. If it were desired to make the engine run twice as fast, that could be done by replacing the pulley on the horizontal shaft by one of twice the diameter, so that the governor would still turn at the same speed, while the engine was going twice as fast. It would increase the power of the governor to work the throttle-valve, if it were allowed to run at 200 revolutions whilst the engine made 100; to do this we might make a brass or hard-wood pulley of 3 in. diameter, and key it upon the boss of the eccentric, over the present groove; then a spring or weight would have to be so arranged as to bring down the arms of the governor, when making 200 revolutions, to their normal, or midway, position—the one they now occupy when revolving at 100 revolutions. A weight could be arranged as shown dotted in Fig. 25; and springs might be applied as shown sketched at Figs. 58 and 59. It is not proposed to show how to calculate the spring or the weight, because it is a very easy thing to test the governor by spinning it, counting the revolutions, and then making the pulleys to the correct size. In Fig. 58 it is supposed that four small eyes are screwed into the centre of the balls on both sides, so that a couple of springs can be fixed to draw the balls together. A neater plan is shown at Fig. 52; here two notches (*n*, *n*) are filed in the knuckle of the governor arms, into which enter the ends of the bow spring (*s*); these ends are kept in place, sideways, by the slot in which the arms move, whilst the middle of the bow is pierced with a small hole, and passes over a small pin (*p*) screwed into the lower part of the little ball, the upper part of which has been cut away. Supposing it be decided to use a spring, a little flat one of this kind would be very easy to make and apply; the pulley on the horizontal shaft of the governor could be driven off a groove on a chuck in the lathe, then the governor could be spun till the arms took up their midway position, when the revolutions would be counted; if the rate were evidently too great, the spring would be taken off, and weakened by grinding it a little thinner. When the arms of the governor come to the mean position at about 250 revolutions, the adjustment would be correct. It would be

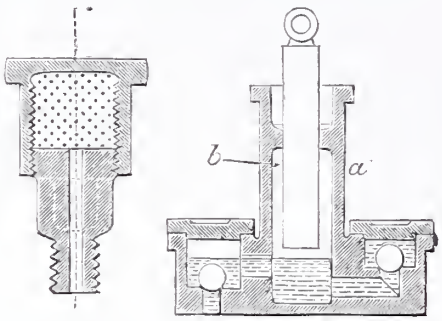

Fig. 60. Fig. 57.

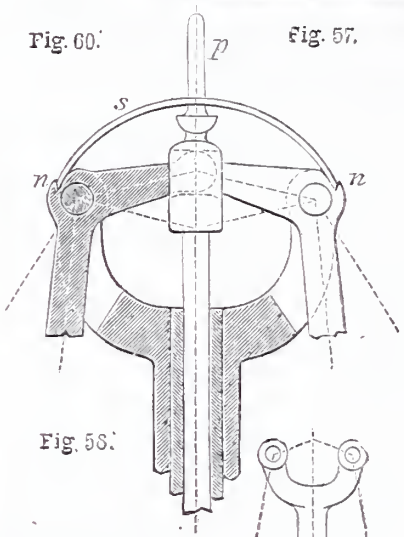

Fig. 58.

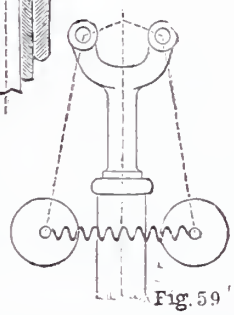

Fig. 59.

Fig. 57.—How a Feed-Pump should not be made. Figs. 58, 59.—Two Methods of applying Springs to Governor. Fig. 60. — Section of Stauffer Lubricator.

well also to ascertain what speed is required to raise the arms to their highest point and close the throttle-valve, and, again, at what speed the arms begin to rise; we might expect to find 240 revolutions would raise the arms, 250 bring them half-way up, and 260 raise them to the highest point; then, if the engine is speeded to run at half the revolutions of the governor, it may vary in speed from 121 to 130 revolutions per minute, but would not in practice vary more than ten revolutions, except under exceptional circumstances. It might be impossible to count the revolutions of the governor, but it would be easy to count the lathe mandrel, and the groove on the chuck could be made twice or three times the size of the pulley on the governor shaft.

I cannot say, certainly, that our engine with such a governor as we have now described would be sufficiently steady to drive a dynamo: I think it would; and with a good boiler, large enough to run the engine at 200 revolutions, I am led to believe it would light about six lamps of 10 candle-power.

*Lubricators.*—Something must now be said about the lubricators. These, it will have been noticed, are not of the usual kind; should anyone wish to use the common kind of oil cup, they can of course do so, or they can do without any cups. The ordinary oil cup, however, requires to be set in a vertical position, which these do not. The lubricators shown in our engine are the smallest size of Stauffer's patent lubricator, and cost one shilling each. They are filled with a kind of grease which looks like yellow cold-cream. A section of one of the lubricators is seen in Fig. 60. It consists of two parts: a cap, which is filled with the grease, is screwed down upon the other part till the grease is forced down the small hole into the bearing; as the shaft revolves it distributes the grease, which soon begins to ooze out at the sides of the brasses; the bearing is then ready for work, and will require no further attention for a day or so, or even, perhaps, for a week; even when a fresh supply of grease is required, it is only necessary to give the cap about half a turn with the fingers, so as to force out a little more grease into the bearing; when the cap has been screwed quite down it must be re-filled. No oil runs or drops about to make a mess, and nothing could be cleaner or more convenient. This form of lubricator can be used in any position: it may be horizontal, as on the eccentric and connecting-rod; it may force grease into several rubbing surfaces at once, as that on the top of the cross-head; it may be placed upside down, or it may revolve with the boss of a loose pulley. No lubricator has been provided for the slide-valve and piston, because when working at moderate pressures the water contained by the steam lubricates sufficiently. A simple way to lubricate both slide-valve and piston at once is to arrange an oil cup so that it may deliver into the steam-pipe; by thus lubricating the steam-pipe, the oil is carried to all the rubbing surfaces inside.

The exhaust-pipe is supposed to be simply screwed into the cylinder casting: it leads downwards, to carry off the water; it may be led down towards a drain and a hole made at the lowest point there, to allow the water to escape; after which it may turn upwards to carry the bulk of the exhaust steam into the air.

Cylinder cocks are shown to carry off the condensed steam from the cylinder; they are opened at first starting the engine, when the cold metal of the cylinder condenses a good deal of steam; they are both moved by one handle. These taps cannot really be considered necessary on such a small engine, especially with a descending exhaust.

All drips or leakage about the engine should be prevented as far as possible. Engines are often seen working without the slightest whiff of steam appearing even at the stuffing-boxes. It would be very undesirable in an amateur's workshop to have an escape of steam, as it would be liable to rust the bright work about the lathe, tools, etc. The stuffing-box of the stop-valve is liable to leak, and this valve-cock should be screwed on the right way up—that is, in such a way that when closed the steam should be shut off from the stuffing-box. A little tin tray may be hung by a wire under each stuffing-box gland, so as to catch any

drops that may fall; the pump gland is one especially liable to drop and make a mess.

*Lagging of the Cylinder.*—The "lagging" or wood casing surrounding the cylinder appears in Figs. 4, 5, 7, and 25; it is useful in two ways: first, it prevents loss of heat from the cylinder, and consequent loss of power; and secondly, it prevents the engine from unduly heating the apartment in which it works; also it looks well if nicely fitted, the wood polished, and the brass bands kept bright. The cylinder would first be clothed with felt or, say, part of an old blanket; then the wood lagging in strips of mahogany; and then the brass hoops secured as seen in Fig. 7; or, otherwise, instead of the hoops there might be a piece of thin sheet metal bent round the wood and painted.

*Steam Joints.*—Making the steam joints is a very simple thing. Buy a little red-lead powder and some white lead (in paste) from the ironmonger or colourman; mix a little red-lead powder into some white lead just to stiffen it, work it well together, and rub this on to the threads of the screws of the pipes before screwing up. It is usual to spread some of this same cement between the flat surface joints, such as those of the cylinder cover, valve-chest, etc., but I have used a piece of red blotting-paper with complete success. It was cut out with holes for the bolts, and when cut round the edge of the joint, looked as if it were a red-lead joint, with the advantages that you could take it apart as often as you wished, whilst none of it squeezed out of the joint into the inside of the cylinder. It would be an advantage to oil the blotting-paper before screwing up the joint.

*Foundation.*—There are three lugs provided on the bed-plate, by means of which the engine can be bolted down upon a foundation. The foundation may be a frame of wood made so as to raise the engine high enough to allow the fly-wheel to run clear of the floor; or it might be a stone, the foundation bolts being fastened in with lead. It is convenient and suitable to have the engine raised above the floor, at any rate as high as a chair, because it is more easily got at. When not at work, it should be carefully covered with a cloth or piece of green baize, to keep it from dust and damp, remembering that dust and grit, and above all emery-dust, must not be allowed to get on to the sliding guide nor into the bearings.

*Driving Belt.*—The fly-wheel, being 16 in. in diameter, a flat belt round this wheel should transmit all the power the engine is capable of exerting without being unduly tightened. It is well to arrange for the belt to run upwards, because then it may relieve the bearings of most of the weight of the fly-wheel; and it is better, if the belt must be inclined upwards, to arrange it to incline forwards, from the engine, not backwards, towards and over the engine; because, in the first case, the pull of the belt would tend to cause wear upon the middle of the upper brass of the crank shaft bearing, which wear can be taken up by tightening the cap of the bearing; but in the second case the wear would come upon the sides of the brasses, where they are divided, and here the wear cannot be taken up.

I will now take leave of my readers, heartily wishing them good success.

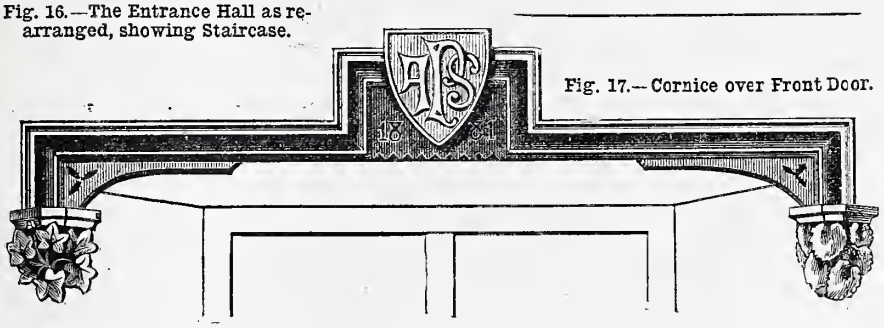

Fig. 17.—Cornice over Front Door.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

THE ENTRANCE HALL—THE STAIRCASE—THE FRONT DOOR—THE STUDY DOOR—THE WALLS.

*The Entrance Hall.*—All those among us who find pleasure in the tasteful arrangements of our homes are, I believe, of one mind as to the desirability of having an entrance hall deserving of that name, and one which can properly be called by it. Comparatively few, however, of those who, like myself, are not born to fortune, can indulge in the luxury, for the majority of small houses have, instead, nothing better than a miserable passage. Fortunately, in my house I found a real hall, though but of small dimensions. It was not passage-shaped, but almost square, viz., 12 ft. by 11 ft. On each side of it was a door—westward to the public street, northward to the study, southward to the dining-room, and eastward to a parlour (for it seems absurd to dignify this little apartment, scarcely more than 12 ft. square, with the title of "drawing-room"). The stairs also rose from it, and, indeed, much of the northern side was occupied by the lower part of the staircase.

*The Staircase.*—When I entered upon the house this same staircase was by no means a sightly feature. It was, in its lower part, completely enclosed; at its side it was shut in by a lath-and-plaster partition, and at its foot by a door. It thus detracted from the apparent size of the hall, and prevented its giving a due impression of its shape. As for the stairs themselves, they were of bare elm board, strong, certainly, and sound, but bleached with the soft soap and scrubbings of a long course of years. They looked unpromising, but elm is always a hopeful kind of wood: under proper treatment it will generally develop a pleasing grain and a good colour. Accordingly I brushed them over with hot boiled oil, so far as they would not be covered when carpeted, and polished them with beeswax and turpentine. I found that they repaid my trouble.

The door at the stair-foot I cleared away, and removed all traces of it. A reference to Fig. 16 will show in what manner I dealt with the partition at its side. To have removed this partition bodily, and substituted a balustrade, would have been too serious an undertaking for me, nor did I see any pressing necessity for so doing. Among other wreckage of "restored" churches, I had secured a set of discarded communion rails, which were good solid oak-work of the seventeenth century. I cut out a portion of the partition, as shown in Fig. 16, and in the opening inserted a length of this railing. For the remaining portions I found employment as balustrades on the landings of the two upper storeys, where some shabby painted deal rails had to be removed. Of the alteration in the

entrance hall, I may say that it sufficiently lights the previously dark stairs, and throws the staircase open to view; moreover, its quaint and unusual appearance renders it, to my thinking, more pleasing than a regular balustrade could have been.

As with the new arrangement the post at the stair-foot had a somewhat bald appearance, I looked through my stock of old oak carvings, and found two demi-figures, which I nailed upon it in the manner shown in Fig. 16.

Beneath the staircase was a closet opening from the hall by a shabby painted door. This door I also took away, and substituted for it that which appears in the illustration (Fig. 16). The carving seen upon it is of the same kind as that on the dado of the study, though of a different pattern, and is my own work. The door itself is of old oak panelling of the time of James I. The view of the staircase in its present form (Fig. 16) is as it appears through the open door of the dining-room.

*The Front Door.*—The opening to the street door as seen from within was by no means pleasing. It was of considerable width, the walls, which were very thick, being splayed away inwards; and I had to consider how, whilst improving its appearance, I might also arrange for the hanging of a heavy curtain during the winter months. Fig. 17 will give some idea of the plan adopted. The cornice there shown is made from a bold steam-struck moulding (of which it will be presently seen I used more elsewhere), and which, like the board to which it is attached, is ebonised. On the scutcheon in the centre I emblazoned my monogram on an azure ground. The curtain itself is not there, nor is the rod shown by which it may be hung. This is another fragment of the wreck of the four-poster, on which it once figured as the foot-rod. Like its fellows in the "den," it is enamelled vermilion. The cornice is made to rest on two corbels, which were cut by me from the soft stone of the country (white lias), and which are let into the wall for that purpose.

*The Study Door.*—I have mentioned that the study had old-fashioned ledger doors—doors of plain boards nailed upon cross-pieces—and as the other doors which opened from the hall were panelled, that to the study, which was close by the stair-foot, looked out of keeping in its original state. Accordingly, with some strips of narrow moulding, I marked out two panels; throughout their length I carefully puttied up the central chink, and upon them I painted in monochrome a sort of conventional foliage scroll, as shown in the illustration. The panels are of a Pompeian red; the other parts of this and the other doors black.

*The Walls.*—These I contented myself with papering with a dado paper; and, in the absence of any other cornice round the ceiling, I fixed up one of ebonised moulding similar to that in the study, namely 1½ in. deep; but, as will be seen from the illustrations, I arranged no frieze here.

My entrance hall being thus reorganised, I furnished it with a small, dark, carved oak table, and two ancient carved chairs, one of which shows in Fig. 16. Its walls were now no unsuitable place round which to hang antique weapons, scraps of carving, fragments of armour, and such like curios which men of the tastes of its owner ever find delight in accumulating, and which are as appropriate in this position as old china, bits of bric-à-brac, and Japanese fans, and screens and other fanciful means of ornamentation are in the drawing-room.

## PRACTICAL PAPERS FOR SMITHS.

BY J. H.

TEMPERING MIXTURES: WATER—MEDICAMENTS—OILS AND FATS—LEAD BATHS—HARDENING BETWEEN COLD METAL—FICTION *v.* FACT—EXTREMES OF TEMPER—EXAMPLES—TAPS—DIES—DRILLS—MILLING CUTTERS—AXES—MILL PICKS—SPRINGS.

My remarks in this article will have reference to the different kinds of tempering mixtures used, and the special treatment adapted to various tempered articles. Owing to pressure of business I have not been able to send in these "Practical Papers for Smiths" as quickly as I could wish; I shall, however, do my best to complete the section of my subject selected for treatment in the present volume of WORK in two more short papers.

*Tempering Mixtures: Water.*—Water is the commonest medium used for quenching steel, and hard water is not so suitable for tempering as soft or rain water. Moreover, smiths do not change the water in their tempering tanks, but simply add fresh in sufficient quantity to make up for waste. They have an opinion that water which has been long used is preferable to fresh water. It is supposed that the virtue attributed by smiths to that which has been long in use may be due to this: that the frequent warming of the water by red-hot metal has driven off the air contained in it, and allows the fluid to come into more intimate contact with the surface of the steel than when normally impregnated with air. The belief that boiling the water is beneficial may be explained in the same way.

Pure cold water is very commonly used for ordinary tools, such as chisels and drills; but for other and more difficult work, warm water, or water medicated with various substances, is found more suitable.

*Medicaments.*—Thus, a good tempering bath is made by adding half a pint of common salt to a gallon of soft water, and brine of various degrees of saltness is one of the most favourite mediums employed for quenching tools. But many other salts are also extensively employed. The salts of potassium, ammonia, mercury, and boron are in much request. Ferro-cyanide of potassium is frequently used in tempering baths, along with salt and borax. About half a pound each of potash and borax, and about six ounces of salt, pulverised and dissolved in ten gallons of water, make a good bath.

But the hardening effect of water is too intense for many classes of articles, for which oils and fats are better adapted.

*Oils and Fats.*—Linseed oil is very suitable for tempering small springs and other articles in. Beef suet, grease of various kinds, refuse of fats and oils, used alone, or mixed with pitch and resin in various proportions, are also used for spring steel.

*Lead Baths.*—A bath of molten lead is a good heating agent for many articles up to the temperature for tempering. In it also articles of unequal thickness can be heated uniformly. The lead is prevented from oxidation by covering its surface with powdered charcoal.

The temperature of a bath of pure lead is of course uniform, but by making alloys of lead and tin in various proportions, an extensive range of temperature is obtainable, suitable for work of different classes. The following table, taken from Dr. Percy's "Metallurgy of Iron and Steel" (p. 854), will serve to show what can be done by means of such tempering baths of alloy:—

TABLE OF THE COMPOSITION OF METALLIC BATHS FOR THE USE OF WORKING CUTLERS.

| *No.* | | *Composition of the Bath.* | | *Temp.* |
|---|---|---|---|---|
| | | *Lead.* | *Tin.* | *Fah.* |
| 1 | Lancets ... .. ... ... | 7 | 4 | 420° |
| 2 | Other surgical instruments ... | 7½ | 4 | 430° |

*Hardening between Cold Metal.*—It is not even necessary that hardening should always be done in liquid. If a thin heated plate is placed between two pieces of cold metal, it will become hardened as effectually as if in water or oil. This is often done, because it tends to lessen risk of warping of the plate.

*Fiction v Fact.*—It may be suspected that many of the various medicaments employed in hardening mixtures, and the use of so many different proportions of oils and fats, are more fanciful than valuable—more of the nature of supposed trade secrets than of vital importance. This may be the case in some instances, but I doubt if it is often so. A workman finds that he can obtain certain excellent results by the use of such and such compounds, which he cannot, or does not, obtain by the use of any others. That man is always working in that line, and surely ought to know what is best. Tool makers often keep their knowledge to themselves, thereby giving the best possible proof of their belief in its value. It is also certain that a knowledge of the relative conductivity of many of the mixtures employed often fully bears out the wisdom of the smith's practice. Mr. Godwin Austin referred to this matter in an address delivered before the British Association in 1889. He remarked: "But cold water was far too simple a material for many a sixteenth century artificer to employ, as is shown by the quaint recipes contained in one of the earliest books of trade secrets, which, by its title, showed the existence of the belief that the 'right use of alchemy' was to bring chemical knowledge to bear upon industry. The earliest edition was published in 1531, and the first English translation in 1583, from which the following extracts may be of interest:—'Take snayles, and first drawne water of a red die, of which water being taken in the two firste moneths of harvest when it raynes; boil it with the snayles, then heat your iron red hote and quench it therein, and it shall be hard as steele. Ye may do the like with the blood of a man of xxx. yeres of age, and of sanguine complexion, being of a merry nature and pleasaunt . . . distilled in the middst of May.' This may seem trivial enough, but the belief in the efficacy of such solutions survived into the present century, for I find in a work published in 1810 that the artist is prettily directed to 'take the root of blue lillies, infuse it in wine, and quench the steel in it,' and the steel will be hard. On the other hand, he is told that if he 'takes the juice or water of common beans and quenches iron or steel in it, it will be soft as lead.' I am at a loss to explain the

confusion which has arisen from this source. As must always be the case when the practice of an art is purely empirical, such procedure was often fantastic, but it is by no means obsolete, for probably at the present day there is hardly a workshop in which some artifice could not be found with a claim to possess a quaint nostrum for hardening steel. Even the use of absurdly compounded baths to which I have referred was supported by theoretical views. Otto Tachen, for instance, writing of steel in about the year 1666, says that steel when it is 'quenched in water acquires strength, because the light alcaly in the water is a true comforter of the light acid in the iron, and cutlers do strength it with the alcaly of animals;' hence the use of snails. Again, Lemery explains in much the same way the production of steel by heating iron in the presence of horns of animals." How much are modern theories nearer the mark?

But the belief, as old as Pliny—who maintained that the quality of steel depended on the nature of the water used in the process of hardening, and who mentions the use of oil for tempering where water would have too great a hardening effect—is still held and acted on by every smith in large factory and country forges, and is in the main correct, both in practice and theory.

It is not surprising that different men differ so greatly in their statements respecting the working of steel. Welding and temper depend for their efficiency not only upon minute differences in grades of steel, but also on the minute alterations of colour that indicate grades of temperature. Intensity of colour is a matter of individual opinion, and depends also on the light in which it is observed. A colour that looks bright in a dark shop or on a dull day will not be so bright under contrary conditions. Matters like this have to be borne in mind when endeavouring to reconcile statements apparently at variance. Much also depends on what previous hammering a tool has undergone. Hammering at a low red heat closes up the fibres and renders the steel better adapted to take a good temper. The thinner a tool, the more difficult it is to temper. The greater the length of that portion of a tool which is tempered as distinguished from that which is hardened, the better will be the temper. That is, if a tool is only dipped for a length of ½ in., and then let down, it will not be so reliable as one that is dipped 1 in. or 1½ in. There is no end of little matters that affect the ultimate temper of steel articles. A man may spend his whole life in such work, and still confess himself ignorant of many matters of an apparently occult character. For this reason, no one should dogmatise about the virtue of his own special methods to the exclusion of others, probably equally good.

*Extremes of Temper.*—In tools the maximum of hardness and elasticity combined is obtained by tempering at a straw colour. Quenching at a red heat makes a tool intensely hard, but brittle. Quenching at a blue makes it elastic, but soft. Between these extremes the whole practice of hardening and tempering lies.

I instanced the chipping chisel in the last article as a typical case of hardening and tempering; I will now refer to some other tools.

*Taps.*—Screw taps are conveniently heated in an iron tube, large enough to allow not only of the admission of the tap, but also of the tongs by which it is manipulated. The tap must be kept slowly revolving within the tube, in order that the temperature may be equally distributed throughout. The same method will be employed for heating the tap, both for hardening and for tempering. The tool is first hardened by heating to a dull red in the tube. The temperature must be raised gradually and very slowly, and equally throughout. If heated rapidly, the edges of the threads will be at a higher temperature than the interior, and being probably too hard, will crumble off in use. A dull red must not be exceeded; in fact, it must be an invariable rule to harden and temper taps at the lowest heat practicable. It is better to make two or three attempts, increasing the heat each time, rather than to rashly overheat at once and spoil the tool. It is then plunged vertically into lukewarm water, and held there until quite cold. Afterwards the flutes are brightened with emery and oil, and heated to a light straw in the tube, and quenched for temper.

Some use linseed-oil baths for quenching taps and dies. It is, however, a good precaution to use soapy water. Also the points of the threads may be protected with a coating of soft soap, or with a paste made of prussiate of potash and flour, or yeast.

The specific gravity of hardened steel is less than that of unhardened steel. Hardening, therefore, has the effect of slightly expanding the steel, and taps are screwed very slightly less in diameter than they are required to be after hardening. Other tools that are turned in the lathe before hardening, such as D-bits, fluted reamers, and rose-bits, are also for the same reason turned bare to size.

*Dies.*—Dies are first heated to a cherry red, and hardened in salt water. To diminish the risk of cracking, they are covered with prussiate of potash or with a paste of soap and oil. The faces are polished, and the dies heated on a hot piece of iron, taking care to turn them over and over until they are of a straw colour, dark, bright, or medium, according to circumstances. A bath of linseed oil may also be used for tempering.

Worn dies are not thrown aside, as a rule, but are re-cut. Before they can be re-cut, the temper must be completely drawn by annealing. This is done by heating the dies to a light cherry red in a clear fire, and covering them with sawdust and ashes until cold. Or they are enclosed in an iron tube, and heated with charcoal or leather cuttings, and allowed to cool. Other tools, such as broaches, milling cutters, reamers, and lip drills, when worn, are similarly annealed preparatory to re-cutting. Afterwards they are tempered just as in the case of new tools.

*Drills.*—Drills for cutting iron are tempered at a dark straw at the cutting edges. The remarks made in reference to the hardening and tempering of cold chisels in the last article apply equally to drills for iron.

Drills for boring hard steel will be heated and quenched in a lump of lead, and not drawn afterwards. Glass may be drilled with such tools by the assistance of paraffin or petroleum for lubrication, placing a cork underneath the glass beneath the drill to deaden vibration.

*Milling Cutters.* — Milling cutters are heated to a red, dipped into oil until the red colour disappears, and then transferred to water, and left till cold; then heated to a light straw, and cooled.

*Axes.*—Axes are hardened and tempered very much like chisels. They are heated first to a red, and quenched to a depth of two or three inches in water. A face is polished, and the changing tints observed until the appearance of a deep blue, at which total immersion is made for temper. As in other tools, different shades of blue, inclining towards a brown straw, will be required for different grades of steel.

*Mill Picks.*—Mill picks are not tempered in the common acceptation of the term, but hardened only. They are heated to a dark red, and quenched finally, the temper thus obtained not being drawn, or let down, as in the case with most of the tools already noticed. Pure soft water is quite suitable for these, and yet most smiths use medicated mixtures, into the composition of which salt, alum, sal-ammoniac, etc., enter.

*Springs.*—Springs are first hardened in the usual way by heating to a cherry red, and quenching in water. Then they are smeared with tallow or lard, and heated in the fire or over the fire, moving them to and fro until the tallow catches fire, and blazes and burns off. When burned off, the springs are laid upon the forge, or on the ashes to cool down. If the work is of irregular thickness, the burning of the oil should be repeated two or three times.

Small springs made in quantity are often put into a sheet-iron pan and covered with oil, and held over the fire until the oil blazes and burns off. Moving and shaking the pan about causes the temper to be more uniform. In the case of heavy springs the operation may be repeated twice or three times.

## A GIRTH-TIGHTENING WHIP CROCK.

BY J. C. KING.

THE buckhorn of a hunting whip is termed a "crook" or "crock," but sometimes iron, nickel, or brass is used; a whistle is often formed in the crock, sometimes a spring loop to take the rein of another horse, or for similar uses. But the best use is to form of the buckhorn a grip for tightening the saddle-girths.

A Girth-Tightening Whip Crock.

It is simply done: a flat is cut on one side of the horn and roughened with cross-cuts as of a file; a hole is bored in the end near the socket that takes the whip handle or "crop," and a small mortise an inch from the end at the edge of the roughened horn is made. A nickel vice-jaw, an inch long and ⅜in. wide, is the movable jaw, which turns only about ⅛ of an inch in the mortise, the turning being on a long screw through the projecting angles of the jaw, and lengthways of the buckhorn crock. The jaw is always a quarter of an inch open till closed with the thumb pressure, which causes it to grip the leather of the saddle called the "point," which takes the girth-buckle.

The illustration shows the whip being used by the huntsman's hand pressing up the saddle-point strap, and drawing it through

BORDERS. Fig. 1.—Cut Border: Foliage. Fig. 2.—Cut Border: Drapery. Fig. 3.—Small Wood Block for raising Border. Fig. 4.—Arrangement for raising Border. Fig. 5.—Border (A) with Pulley Blocks (B) and Dead Lines (C). Figs. 6, 7.—Borders representing Ceilings of different kinds.

the girth-buckle. With this grip the fingers are not strained, as the power of the hand lightly used is sufficient to draw a girth tight. Grooms often catch hold of the girth-point with their teeth, to their injury. The metal jaw is not in the way, and weighs about half or three-quarters of an ounce The equestrian readers of WORK are welcome to the use of the invention.

## STAGE CARPENTRY.

BY WILLIAM CORBOULD.

### BORDERS, GROUND ROWS, ETC.

BORDERS are classed under several heads: such as sky borders, tree, interior, and drapery borders. The making of them is the same, as far as battens and canvas go, but the painting is quite another thing; of that, further on.

In making a border, the most particular thing is to have a good batten of sufficient strength to keep the canvas straight and flat, especially sky borders. There should be no creases; the reason is obvious. Suppose we have a border, say, 15, 20, or 30 ft. long, and 3 ft. or more deep, you must stretch your canvas on a frame or some flat surface. After you have done this, make some good priming. What I mean is, let your size be strong, but not too much whiting, as borders, as a rule, get a deal of knocking about; if you had too much whiting they would crack and show bad places. When your priming is dry, it will be ready for painting, if a sky border; or for an interior ceiling or drapery, it would be ready for drawing in your subject. Should there be cutting-out to do, such as hanging branches and leaves of trees, or drapery (see Figs. 1 and 2), you would, after painting, take the border off the frame, lay it flat upon the stage or floor, and tack it to your batten; you may then hang it up, say, shoulder high, when you can cut, foil, or do anything you wish. After it is all complete, you may hoist it into its place, hanging it with two or more "dead lines" to beams, rafters, or any place of safety with "screw eyes" having a firm hold. Should the borders be required to rise and fall, small blocks would have to be used.

With regard to blocks, I would advise the amateur to use small wood blocks (see Fig. 3). They are far better than the iron (Fig. 4), as the wood blocks will work about with the pulling of the ropes; on the other hand, the iron ones, being fixtures, soon cut the ropes. If you have movable borders, always have good dead lines attached, to prevent accidents (see Fig. 5; A, border, B, B, pulley blocks, C, C, dead lines), for should the block lines give way, the dead lines would prevent the border from falling.

When representing interiors, be careful with the perspective; although a border may be hanging down, it may be made to appear flat by attending to your perspective (see Fig. 6, representing an old ceiling with oaken beams, and, may be, plaster between them). Fig. 7 might be that of an old baronial hall. Fig. 2 is a border drapery, such as a proscenium front; this may be of different colours, such as crimson, blue, green, or amber, with gold or silver bullion fringe and ornaments. I shall give a description of their painting and manipulation when I treat of drapery painting.

We now come to ground rows or borders, rises and sinks, etc. A ground row may

consist of rocks, banks, foliage, water, etc.; they are usually fixed by small dogs (see Fig. 8; A, B, C). Supposing you wished to represent, say, Loch Lomond, with its numerous islands—I have done this with six border rows; the first—that is, the one nearest the footlights—would be painted, the water rather rough, such as a stiff breeze would cause; the next border would be less rough, the third still less than the second, and so on with each one, the last being quite flat and pale in colour, the colour in each growing less in strength; you thus get a broad flat surface in proper perspective. Where you wish to represent an "island" you raise it with profile, as in Fig. 9. Boats may pass between the borders. Some years ago I painted the scenery for the gathering of the "Scottish Clans" at the Theatre Royal, Stockton-on-Tees. The chiefs were represented by children in a boat drawn by two swans; the water being frosted, the moon shining full down on the lake, the beacon fires on the hills, and signal lights of different colours, combined to make a splendid scene.

The *Colleen Bawn* is another play where, in the cave scene, water rows are used with a boat. Sometimes water rows are made with gauze, either pale blue or green; or the water painted—that is, the waves or riplets painted on the gauze, this being held in its place by two iron pins from the wings. A cord through the top of this gauze could be also fastened to the wings.

*Rises and Sinks.*—These are borders which rise through a slide or trap in the stage (see Fig. 10) managed by counter weights; used principally in transformation scenery. To give a description here would be impossible. This all depends on the fancy of the author or artist, which might be weird, grotesque, or any beautiful subject, such as the "Coral Caves of Neptune" or "A Cavern of Sparkling Gems."

In Fig. 10, C C is slide open; A, ground row rising; D, D, counter weights, manipulated from under the stage; at B, on the dotted line, the cord is fastened to the bottom of the border, the cord passing round the grooved wheel, the weight being gently pulled down by the hand.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Boring Holes.

There are a great variety of tools used to make holes in wood, and apart from the question of size, which is of importance, there is also a question of suitability. We will look at a few of these tools. Bradawls are well-known and useful tools for soft wood. Having a cylindrical stem, and being ground to a chisel edge, shows the observant amateur that the chisel having cut the fibres, the wedge-like form of the tool pushes them aside; used in end grain it scrapes and pushes its way in, and though roughly, yet effectually makes room for a nail or a screw. I am far from denying that the bradawl can be used for hard wood, but its special use is for soft wood, and its province is limited to comparatively small holes. In hard wood it is to be turned back and forth more freely than is necessary in soft wood, the edge acting more like a scraper in the harder material. The great fault of the bradawl is that no provision is made for the waste material, which is the reason why it is limited to small holes.

Gimlets are equally well known. They may be regarded as useful tools for the tool-basket, having the merit of portability, boring large pieces of hard wood fairly well, and being just as suitable to bore end grain as across the fibres. Let no one, however, trust a gimlet to bore a hole near the end of a narrow strip of wood; the pointed screw, drawing the tool rapidly into the compact wood, is like a wedge, in that it splits the wood quickly.

For small holes in hard wood a small spoon or pin-bit is very suitable, and if the pin-bit is sharpened from the inside as well as the outside, it will cut better. A good all-round bit is that called "diamond twist;" it is in effect a twisted spoon-bit, and good

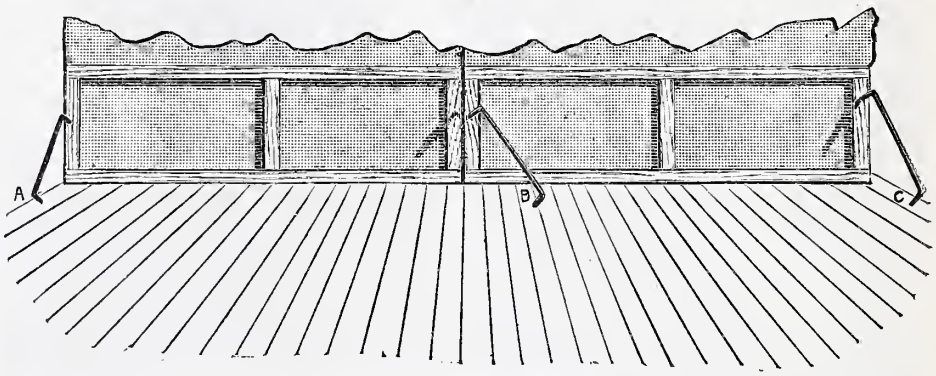

Fig. 8.

Fig 9.

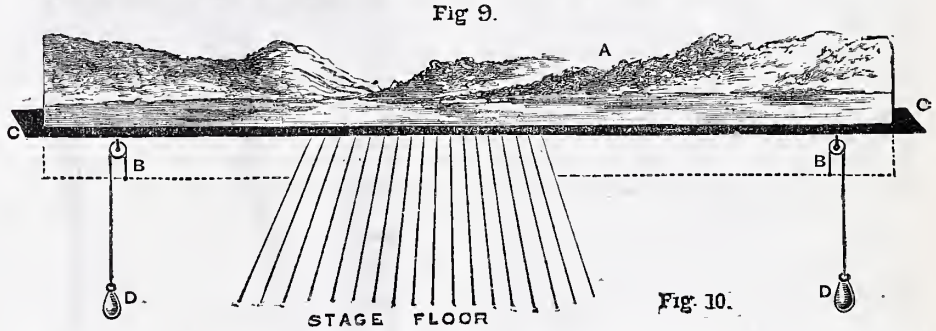

Fig. 10.

**GROUND ROWS, OR BORDER RISES, AND SINKS. Fig. 8.—Ground Row—A, B, C, Small Dogs. Fig. 9.—Ground Row. Fig. 10.—Ground Rise and Sink, showing the Scenic Portion comprised therein (A), with Pulleys (B).**

piece of wood; it has an almost continuous circular cutting edge, and two cutters to remove the inside wood. I have not tried it, but it seems to have all the requisites of a good tool.

Clark's expanding bits are excellent for organ-builders and others who require great variety of sizes; they work well, and would cost less than the number of centre-bits, whose work they are capable of doing. There is also a new expanding centre-bit recently introduced, but it does not work to perfection; the movable cutter in the one I have is too much like a scraper rather than a chisel. That is a slight fault which doubtless will soon be remedied by the makers.

work can be done by it. Centre-bits begin at about $\frac{3}{16}$ in., but, unless very nicely made, the small sizes are not much good; for holes from $\frac{1}{4}$ in. upwards they are applicable, suitable, and cheap; they do not do well for end grain, and should be kept sharp. The bits that are best for all purposes are Jennings' twist-bits; they combine in one article the advantages of gimlet, centre-bit, and the old-fashioned auger, inasmuch as they have a screwed centre-point, two sharp edges to cut the circle, and two chisel-like cutters like a centre-bit to remove the chips; it has also a polished surface to the spiral flutes, along which the waste easily travels.

Gedge's bit, which has two gouge-like cutters, is nearly as good, and in one respect better, for by its aid you can enlarge an existing hole. There is also a new bit which will cut a semi-circle from the edge of a

### Panels and Frames.

I have treated upon planing, sawing, setting out, and, to some extent, mortising and dovetailing; it will, therefore, involve a combination of several operations which we have learnt to make a frame and panel. A panel, in woodwork, is defined as a piece of board whose edges are inserted in a frame; the panel is usually thinner than the frame, but it may flush—that is, even on one side with the surface of the frame. It may be equal in thickness to the frame, then it is flush both sides, or two thin panels may be inserted in one frame, each panel being flush to a surface of the work. Flush panels are often used for doors intended to be covered with baize or cloth. Sometimes the panel is inserted in a groove, in which case, of course, it must be made, finished, and inserted before the frame is glued up. A

popular novelist once described a joiner, whose thoughts were otherwise employed, as forgetting the panel, and putting the door together without; a clever but an almost incredible illustration of absent-mindedness.

Amateurs must bear in mind that the panels must be inserted, if in a groove and set back from the front, in a perfectly finished condition. For this reason, and because panels are often veneered, carved, French polished, or otherwise ornamented, the frames are often rebated, instead of grooved, for the reception of the panels. In such a case the panels may be fitted after the frame is constructed, and can be removed at pleasure; such a method, which is very common among cabinet makers, is suitable for amateurs. I suppose I need not explain what is meant by a groove; a "rebate," however, is a more technical term. If a piece of the frame is removed, having its edges at right angles to the surfaces of the frame as shown in the annexed diagram at A, it is called a rebate; illustrations of its use can be seen on any picture frame or moulding intended for picture frames. There are many ways of fixing panels in rebated frames, but the method used largely depends on whether the back of the frame and panel are visible; if so, the panel is generally fixed with a bead or moulding nailed or pinned to the frame and not to the panel. The amateur may be well content to fix his panels in this simple way.

Rebate.

Frames and panels should be "square"—that is, unless otherwise intended, they should have the four angles equal, and all right angles. This *cannot* be the case unless the opposite sides are equal; it is for this reason that learners are taught to set out the stiles and rails in *pairs*. If the stiles and rails *are* so prepared, the opposite sides of the four-sided figure are *parallel*, and all we have to do is to see that the diagonals are equal, and we can then be sure that the angles are equal, and are each a right angle. I dwell on this because in large work, such as large window frames, there is no more accurate way of "squaring" the frame than this method of making the diagonals alike, provided always that the sides and ends are equal, or, as the geometricians say, "each to each," and are straight. As I am writing for amateurs, I should like to remind them that the same method of diagonal measurement to determine the angle is applicable alike from land measurement for buildings down to carpet planning or cutting floor-cloth; or, in short, any surface which can be divided into triangles can be plotted and copied, either full-size or to scale, by this plan with ease and accuracy.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 105.—Patent Amateur Parallel Vice.

This neat and handy American tool or workshop appliance may be regarded, and tersely described, as just the "something useful to, and needed by, everyone" who possesses a workshop or workroom, and turns his attention, and devotes his spare time, to doing odd jobs at home. It is true that it is by no means a new tool, and has been, indeed, on the market for years, but it has been improved from time to time as experience has shown to be useful or necessary, and it may now be looked upon as the strongest, most complete, and most serviceable tool of its kind in the market. Nothing but the best car-wheel iron is used in its manufacture, so that the face and jaws are always chilled, hard, and smooth. The

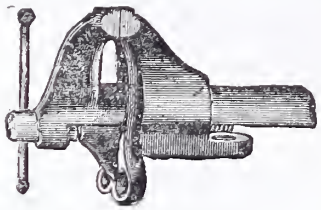

Fig. 1.—Patent Amateur Parallel Vice.

screws are of wrought iron, and the finish of the whole appliance places it at once in the front rank of tools of this description now on sale. Of course, as it happens to be an American tool, there is no necessity to give the name of the American maker, but, for the information of those who may be desirous of obtaining one for his own use, it may be said that this speciality is put on the English market by Mr. H. A. Hobday, Tool and Cutlery Works, Chatham, who frequently advertises his specialities in the pages of WORK. It is made and supplied in the following sizes—

| *No.* | *Width of Jaws.* | *Opening of Jaws.* | *Weight.* | *Price.* |
|---|---|---|---|---|
| 1 | 1 in. | 1¼ in. | 4 oz. | 1s. 0d. |
| 2 | 1½ in. | 1¾ in. | 1¼ lbs. | 1s. 9d. |
| 3 | 2 in. | 2¼ in. | 7 lbs. | 3s. 6d. |
| 4 | 2½ in. | 2¾ in. | 9 lbs. | 7s. 6d. |

The two larger sizes are furnished, it may be said, with an anvil attachment.

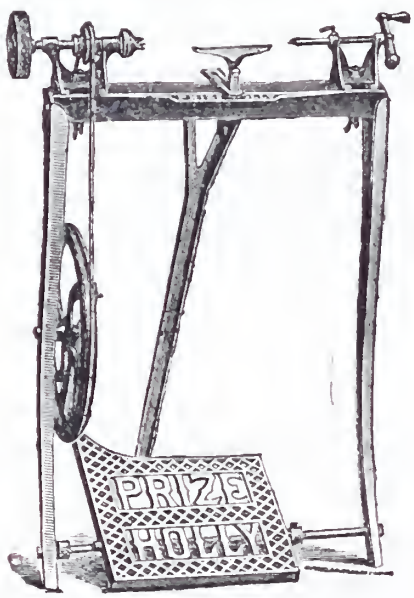

Fig. 2.—Prize Holly Turning Lathe.

### 106.—Prize Holly Amateur Lathe.

This nice little machine, as will be easily understood by readers of WORK, is specially suited for young beginners, and is in no way intended for those who are capable of using and, indeed, require heavier appliances or machines of this class. It is a lathe of American origin, and may be described as first cousin to the Prize Holly Fret Machine, which is well known here, and is to be found among the stock of every dealer in tools, appliances, and wood for fret sawing. Its price is low, costing no more than 21s., and is sent to any applicant, carriage free, at this price by Mr. H. A. Hobday, of Chatham, who, as I have already said when speaking of the Patent Amateur Parallel Vice, is an advertiser in the pages of WORK. Although cheap, it will answer the purpose just as well, and enable its owner to turn out as fine work and as easily as he can with any other small machine now made—the chief difference between it and them consisting in the plainness of construction and in being somewhat smaller in capacity. Its dimensions and capacity for work are as follows: Height of machine, 30 in.; full width, 18 in.; diameter of balance or fly-wheel, 12 in. A piece of wood, 10 in. long and 4 in. in diameter, may be turned on it, so that a pillar, or pilaster or half-pillar, of this length may be managed. The lathe-bed ways are ground and polished, which affords a smooth and level surface for the head and tail block to travel on. It is also fitted with an emery wheel and drilling attachment, and is sent out at the rate specified above with these attachments and three turning tools. Its strength, durability, and rate of operating is said to be greater in comparison than in any other small machine of its size and character; and it is also claimed that, so far as simplicity of construction goes, its equal cannot be found. As Christmas is behind us, and we are already a month and more on our way towards another, it cannot be said that it will make a good Christmas present for an ingenious lad with a mechanical turn of mind just now, but I may as well remind my readers that there are such days as birthdays, and such times as holidays and home-comings from school, when such a gift will be just as acceptable as at Christmastide.

### 107.—"A First Book of Electricity and Magnetism."

Electricity is very fairly—I might say exhaustively—represented in "The Library of Art, Science, Manufactures, and Industries," published by Messrs. Whitaker & Co., seeing that eight of the thirteen volumes that have appeared or are about to be published shortly are devoted to one branch or another of this wide subject. The book now before me, entitled "A First Book of Electricity and Magnetism," has been written for the use of elementary science and art and engineering students, and for general readers by Mr. W. Perren Maycock, M.Inst.E.E., who is Certified Teacher of the Government Department of Science and Art in Magnetism and Electricity, and of the City and Guilds of London Institute in Electric Lighting, and Lecturer on Electricity and Electrical Engineering at the Croydon Polytechnic and at the Whitgift Grammar School, Croydon—offices which, in themselves, are sufficient testimony to Mr. Maycock's thorough capability for dealing with the subject in a lucid and comprehensive manner, so as to render it clear and intelligible even to those who are reputed to be dull and slow to understand. The volume itself, which is abundantly illustrated with engravings of drawings by Mr. Maycock himself and two of his students—Messrs. Checker and Cullingford—is divided into three parts: namely (1) Magnetism; (2) Electro-kinetics, or electricity in motion; and (3) Electro-statics, or electricity at rest. Each part is followed by a series of some fifty questions or more on the subject. At the close of the book a list of apparatus is given, that will be found useful for experiments that should be carried out in illustration, and when treating of each branch of the subject as defined above. Mr. Maycock has been influenced in undertaking the task of providing what he aptly terms "A *First* Book of Electricity and Magnetism" through having found that the various elementary text-books in use, though excellent in themselves, are not elementary in the strict sense of the word, but are somewhat difficult for the beginner—especially the young or ill-educated beginner. The book is written in the simplest possible language, so as to lead nonchalant, dull, and backward students to take more interest in their work than they would if an ordinary text-book were placed in their hands. All teachers under the Science and Art Department will be pleased to know that the book covers the syllabus of the elementary stage.

THE EDITOR.

## A Corner for Those who Want to Talk It.

*** In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Carpentry.**—Markwell writes:—"To such readers of Work as, like myself, have neither workshop nor bench, or even an entirely spare room, it may be of service to know that a very fair amount of pleasure and profit may be enjoyed without them. To make one's dwelling a model of comfort and decoration should be the ambition of every man—and woman too—and where every possible help towards that end is so generously given for the asking to those of a mechanical turn, it does seem a pity that any latent ability should not be cultivated—especially by young people. In my own case the corner of a small room in the back wing is better than nowhere. There is a small fireplace—not much used, for fear of shrinking the wood too much. This is a lesson from experience. Having no place for a bench, I do without it. My makeshift is a fairly strong deal table—15 in. by 27 in.—which cost 7s. 6d. second hand. This was strengthened with well-fitted angular blocks all round glued underneath. In the drawer is a shallow tray—first joh—with divisions for loose screws, nails, and sundries. It stands close to a wainscot partition, and 15 in. from chimney angle, between which and the partition is a recess 10 in. deep. Part of an old table leg is clamped underneath the top at the corner and abuts against the chimney, thus preventing the concern from being shaken to pieces. A lot of small work has been done on this; but for larger and more solid work I bought 6 ft. by 9 in. by 2½ in. of dry pine. This lies level with front edge of table and abuts against chimney, is planed perfectly level and true, and has a stop screwed on near the end. It answers admirably for planing on, and on it edges are planed straight and square by laying the plane on its side and using the left hand to hold the work flat on an additional piece, which raises the edge to about the middle of the plane. In this respect it thus becomes a substitute for a bench screw or wood vice. But one can't do very well without a vice, therefore I have a 'handy' iron one. It is correctly named. The jaws open 3½ in., and are 2¾ in. wide. The screw is square-threaded, is ⅝ in. diameter, and works out of sight in a well-fitting square box; the cost of this was 8s. 6d. This is screwed on the end of a piece of 2½ in. stuff, 30 in. long by 9 in. wide, with two fairly strong 1½ in. screws, because it is often dismounted when this block—the face of which is kept perfectly true—is wanted for other purposes. When the vice is used to hold rather thick stuff for sawing, the block lays across the table, and is, besides being stopped in the ordinary way, held fast by weighting it with my two assistants. My brother 'chips' may like to hear about these. Two 14 lb. lead dumb-bells—made for me many years ago—are mounted on two pieces of wood, 12 in. by 3½ in. by 1 in. The ends are partly let in, of course, and a strap of zinc passes tightly over each end, and is tacked to the edge of the wood. The assistance they afford is so great that I would recommend something of the sort to all tyros."

**Knotting, Splicing, and Working Cordage.**—E. P. B. (*Penge, S.E.*) writes:—"I may say that Mr. Haslope's alternative way of forming 'Tom Fool's' knot by two half hitches is not quite correct, the 'Tom Fool' proper being correctly described by him in the after part of paragraph, and the two knots being slightly dissimilar when finished, as anyone may easily prove. He also passes over the pitcher or jar sling, most generally used afloat. It is made as pattern enclosed, forms a sennit round jar, and is, I think, the most secure of its forms."—[I am obliged to E. P. B. for his criticism. My object being to make these articles a complete manual of knotting and working cordage, I am always glad of any hints or suggestions. I am quite aware that there is a *very* slight difference in the appearance of the knot he refers to when it is made different ways, though for all practical purposes it is identical. I did not therefore consider it necessary to give another illustration merely to show that the strands do not cross one another quite in the same way when the knot is made by the two methods. I do not recollect the pitcher or jar sling he refers to. Perhaps he would kindly give me particulars of it. He speaks of an enclosure in his letter. There was nothing in it when it reached me.—L. L. H.]

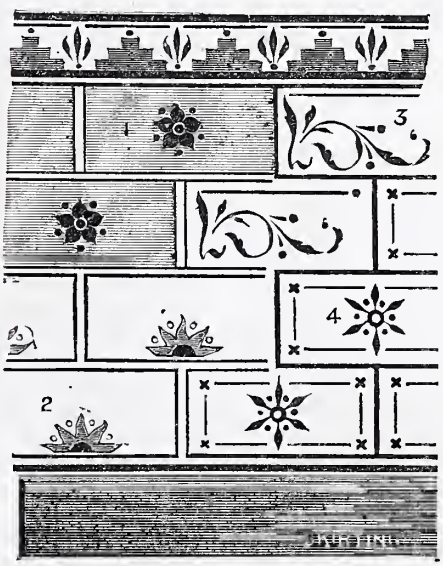
**Hot-Air Engines.**—Messrs. Norris & Henty write:—"In your issue, No. 141, Vol. III., you publish an article on 'Hot-Air Engines,' by Francis Campin, C.E. There are, however, two slight errors. The first is that Messrs. Potter & Co. are not, and never were, the makers of the Robinson Patent Air Engine. This error, however, probably arose from the fact that Messrs. Potter & Co. have placed several orders for these engines for working their ventilating fans, and no doubt have thus become identified with the engine. The other error is in the list of prices, etc. No. 6 is described as ¼-h.p., whereas it gives from 3-man to ½-h.p."

### II.—Questions Answered by Editor and Staff.

**Violin Varnish.**—Constant Reader.—I am not aware of any of the particular varnish you name being in the market; but if you communicate with Mr. James Whitelaw, St. James's Road, Glasgow, he will supply you with some that will answer your purpose admirably.—B.

**Rooms Infested with Bugs.**—Woodpecker.—My advice would be to tear down all papers and lime-wash the walls, to thoroughly scrub the floors and all woodwork with carbolic soap, and to repeat the scrubbing after a few days. Into all suspicious cracks and crevices mercury mixed to a paste with white of egg should be put, or the mercury can be dissolved in milk and put into the lurking places with a brush.—M. M.

**Papering and Painting.**—E. H. S. (*Plymouth*).—Probably you have derived some assistance from papers which have appeared since you wrote. Your painstaking and explicit letter shall, however, be fully answered, and I hope the information will be in time for your purpose. I take it, the porch you allude to is between an outer and an inner door. For this, paint is certainly preferable. Paint it three or four coats, if it is thoroughly dry, according to instructions given in "Painting Billiard-Room Walls." You can make, doubtless, a fair imitation of either grey or pink granites by coating the wall with a ground colour of pink (made with white lead and venetian red), and then, with a piece of honeycomb sponge, marking it when dry with first white and then black paint. Black and white spotted upon a medium grey or lead-colour ground will give an easy imitation of grey granite. A coat of varnish for finishing is advisable. Granite is scarcely what I would use myself; it is rather heavy and a little inelegant. If the work were painted a plain Bath stone colour, the intersecting lines being run in with dark red, you would get a more tasteful effect. If you can draw a little, and cut a simple stencil, better still. You can then carry out the idea the rough sketch above will convey. Use dark red or brown for lines and ornament also. You would only use *one* design, and could easily manage a simple pattern by the aid of a compass. Keep them smaller in proportion, rather, on your wall, than I show. The lines can be made with a straight-edge and lining fitch (see "Painters' Brushes"). I wouldn't advise an attempt to imitate any *marble;* it would, probably, result in a "dauh." Walls should be coated with glue size before being papered. Paste is best made with a small knob of alum in the boiling water used for mixing. Certainly, if you can afford it, varnish hall and kitchen papers. You will not get a paper fit for or worth varnishing for much under 1s. per piece. Don't use good varnish on a common paper; if varnishing at all, have a decent article. "Sanitary" papers, from 1s. per piece upwards, are good value, and can be sponged, but not washed. Paper must be twice coated with patent size previous to varnishing. The size must be applied in liquid form; hence the print of the paper must be made for that purpose, so that it will not ruh up.—Decorator.



**Four Simple Treatments for Ashlar-work Dado, with Border.**

**Electrical Machine.**—W. T. T. (*Houghton-le-Spring*).—The Winter electrical machine described and illustrated in No. 134, Vol. III., cannot be made to produce the electric light. Such machines produce thin currents of extremely high tension. The converse is required for electric lights.—G. E. B.

**Electric Lighting.**—J. A. (*Gristhorpe*).—In No. 99, Vol. II. of Work, at p. 758, under the heading of "Working Dynamo-Electric Machines," you will find my remarks on the use of windmills for electric lighting purposes. My advice to you is, give up the idea altogether. It is not altogether impossible, but is most impracticable for an amateur.—G. E. B.

**Iron Bridge Building.**—J. S. W. (*West Bromwich*).—For particulars as to this, see article on "Wrought Iron and Steel Girder Work," in No. 24 of Work, p. 375.

**Photographic Schools.**—J. D. (*Bethnal Green*).—The only schools with which we are acquainted in which photography is successfully taught are the Guildhall Technical Institute, in the City, and the Polytechnic, in Regent Street, in which classes are held and instruction given by thoroughly competent men. In reply to your other question, the data given are insufficient to permit any definite conclusion being drawn. There are two reasons, one of which is probably the right: First, that you omitted to draw up the shutter of the dark slide; and secondly, the time of development was much too short. Very few plates will develop properly in less than two or three *minutes;* certainly *none* in the time you mention. Interiors of all kinds, well lighted or otherwise, require a longer time to develop than exterior views; from five to ten minutes is not considered long for such subjects, and may sometimes, in certain cases, require an hour or more. You had better procure a shilling elementary hand-book on photography, from which you may derive much useful information.—D.

**Photographic Varnish and Enamelling.**—W. S. (*Harrow Road*).—The varnish you require is made by dissolving 1 oz. of Canada balsam in 4 oz. of pure turpentine; or, take 1 oz. of mastic gum in half a pint of spirit of turpentine or wine, and a couple of drachms of nut oil. I give the preference to the Canada balsam varnish. Before the application of either, the picture must he properly sized by coating it evenly on both sides with a warm solution of gelatine, ten grains to the ounce of water, in which one grain of chrome alum has been dissolved, and permitted to get thoroughly dry. With small pictures, immersion for a few minutes in the gelatine is best, but with large surfaces this is impracticable. If the paper is not properly sized, the absorption of the varnish will cause dark marks, and give a patchy, unsightly effect. If the picture is to be mounted, it should be done before sizing. In reply to question No. 2, provide the following: Supposing there are half a gross of cabinets to he enamelled—two dishes (one considerably larger than the other), a squeegee, a pound jam pot, white wax, 1 oz. Nelson gelatine, a bottle of enamel collodion, and a sufficiency of pieces of glass free from scratches, rather larger than the prints to be enamelled. Set to work by putting the gelatine into the jar, and filling up to within half an inch of the top with clean cold water; leave this to soak for an hour or so. In the meantime polish the glasses on one side, and scribble over them with the white wax: the word "waxed," written large, on them will do. Hold them before the fire to get well warm and the wax melted; then rub them all over with a pad of calico free from size or fluff, and as they get done set them up edgeways one behind the other. Now place the jar containing the gelatine and water in a saucepan of water on the fire till the gelatine is melted and well heated. Into the larger dish pour some boiling water; set the other dish in it, and into this pour the dissolved gelatine. One by one place the prints in this gelatine solution, and leave them there. Now take a waxed plate, and on the waxed side coat it with enamel collodion, rocking the plate to get an even layer. As soon as the collodion has well set, and feels firm to the touch, wash under a tap or in a dish till the greasiness disappears. Now approach the glass near to the prints in the gelatine, and lift one out, laying on the glass face down (collodion side), and with the squeegee passed two or three times over it, to remove the superfluous gelatine and air hubbles; sponge off the face of the glass, and set in a warm dry place to dry. When *quite* dry, the prints will often peel off themselves; if not, a penknife passed under one corner will permit them to he easily stripped off. Note.—All spotting must be done before enamelling, and the colour mixed with albumen, and afterwards dipped in methylated spirit to render it insoluble; also trim the prints beforehand, and they must be mounted before they are removed from the glass support, or they lose gloss. Care must be taken to avoid hubbles between the glass and the picture; they will be observed as silvery-looking spangles, and must be pressed out with the squeegee; but if the prints are carefully laid down in the first place, there will be very little trouble. If the prints stick to the glass or tear, the waxing is not sufficient, or not all over the glass; let the prints get *thoroughly dry* before attempting to remove them, or they will be certainly spoilt. Be careful not to troth up the gelatine solution in pouring from one vessel to another, or by moving the prints about in it unnecessarily. Let everything but the collodion be kept warm during the continuance of the process. When large quantities are enamelled, a number are squeezed on to a large sheet of glass.—D.

**Magic Lantern.**—M. A. P. (*South Shields*).—An article on "How to Make a Magic Lantern," written by a practical hand, is with the printers, and will appear early in the new volume of Work.

**Damp-Proof Developing Shed.**—P. B. (*Clapham*).—Yes, it is quite practicable. An excellent small dark room, called the "Eveready," made by Davenport & Co., Parkhouse Street, Camberwell, for two guineas, would supply your requirements; the size is 6 ft. 6 in. by 3 ft. 6 in. by 3 ft. This is not covered with any waterproof material, but might be made thoroughly watertight by covering it with "Willesden" canvas or paper, and raising it from the ground by a few bricks or battens of wood. An article appeared in WORK a few months ago on "Dark Rooms" which might probably afford you some information.—D.

**Glaze and Red Stains.**—G. G. (*Clapham*).—Glaze is made by dissolving 6 oz. or 8 oz. of good gum benzoin in 1 pint of methylated spirits; carefully strain before using. The benzoin, to be good, should cost not less than 2s. 6d. per lb., and glaze once made improves by keeping. Patent glaze, as sold by most druggists and shellac merchants at about 8s. per gallon, is considered by some polishers to be very good; but for good work, though costing nearly double the price, the home-made article is much to be preferred. If, as you say, you have taken in WORK from the commencement, you must surely have missed the article on "Glazing," by David Denning, p. 338, No. 126, which you will do well to carefully read. Red stains, as made from madder-fustic, brazil chips, logwood, dragon's blood, or red sanders, are now looked upon by most practical French polishers of to-day as old-time methods, and for small jobs is rarely used by them, Bismarck brown having superseded them by reason of its being readily dissolved in water, glue, size, or spirits. It is usually sold at the same place as shellac, etc., at about 6d. per oz., and though this sounds dear, I can assure you that it is not so, owing to its powerful nature. If you have a large job on hand, and prefer the stains as made by chips, etc., I append a few recipes: A light brown mahogany colour may be given by means of a decoction of madder and fustic wood ground in water, ½ lb. madder, ¼ lb. fustic, 1 gallon of water; for a darker mahogany, omit the fustic; add instead 2 oz. logwood chips, which, when dry, should be wiped over with pearlash, 1 oz. dissolved in 1 quart of water; for a bright red, make a strong infusion of brazil chips in water, to which has been added pearlash, 1 oz. to 1 gallon; while the work is still wet with this stain, brush it over with alum water, 2 oz. of alum to 1 quart of water; or, for the same colour, dissolve 1 oz. of dragon's blood in 1 pint of spirits.—LIFEBOAT.

**Newspaper Illustrations.**—T. M. (*Shields*).—The artistic and mechanical stages are generally quite distinct. The drawing is prepared by the artist in black ink upon a smooth card; it is then handed to the photo-etcher, who produces a relief block from it by a photographic and etching process. This is a distinct business in itself, and cannot be practised by a novice. There is one way of combining the drawing and engraving processes—namely, by drawing direct upon a metal plate with a prepared surface by means of a graver. The picture is at once ready for the stereotyper. Apply to the Hoko Engraving Plate Company, 37, Walbrook, London, for particulars.—W.

**Polishing Tinware.**—MAKER BY THE GROSS.—To properly polish tin goods, they should first of all be thoroughly cleaned from spirits of salts, then well rubbed with oil and whiting, then again well rubbed with a dry cloth, and finally polished with a soft duster and dry whiting. I have never found any difficulty in getting a good polish by these means. Of course, in large shops they use a polishing wheel with buffs of various shapes and sizes to buff up the goods, and if you want the same high degree of finish, you must do the same. I am unable to tell you how the bends of hurricane lanterns are made, but most probably with a die-press.—R. A.

**Plumbing.**—NED.—The following are good works on plumbing: "The Plumber and Sanitary Houses," by S. Hellyer, price 8s. 6d., published by B. T. Batsford, 52, High Holborn; "Plumbing," by W. P. Buchan, price 4s., Crosby Lockwood and Son, Stationers' Hall Court, Ludgate Hill; "House Drainage and Sanitary Plumbing," by W. P. Gerhard, price 2s., Spon, 125, Strand, London.—M.

**Robinson Hot-Air Engine.**—E. W. S. (*Egham*).—We cannot give insertion in the body of WORK to the name and address of the makers of this engine.

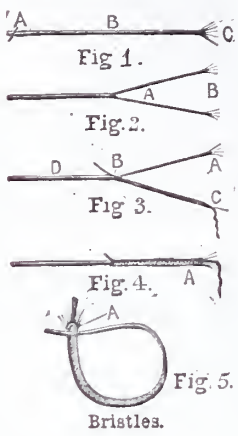
**Scene Painting.**—A. W. B. (*Glasgow*).—The articles on "Scene Painting" appeared in Nos. 92, 95, 97, 101, and 103 of WORK.

**Wardrobe Mirror.**—READER.—Surely in your town, or near it, must be a furniture warehouse; if so, apply to them, stating size and whether bevelled. The carriage from a London firm would, on a single plate, far exceed the price charged extra for the same reason by the provincial firm, who would probably have received their glass in great quantities. The addresses of some London firms have already appeared in "Shop," which you might easily ferret out. Inquire again if still unsatisfied, but meanwhile try the indexes to Vols. I. and II. of WORK.—J. S.

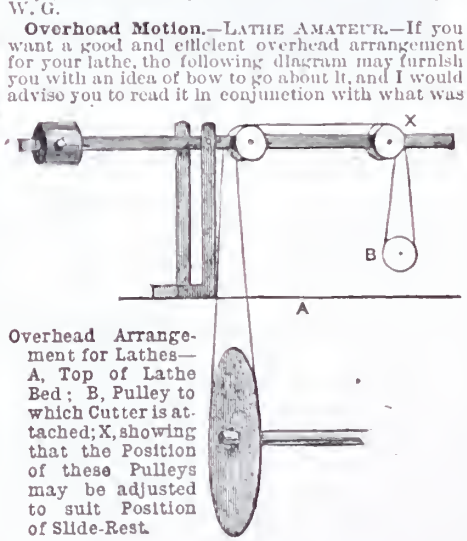
**Tinman's Tools.**—R. L. T. (*Plumstead*).—You will find the illustrations of tinmen's tools and machines in Nos. 67 (p. 209) and 78 (p. 413) of WORK, and you can obtain them by ordering through your newsagent or direct from the publishers.—R. A.

**Lead-Burning Machine.**—A BURNER.—The proportions of zinc and acid vary somewhat in different machines, but you can try the following: 7 lb. of zinc clippings in the lower reservoir, 3 quarts of water and a pint and a half of sulphuric acid in the upper reservoir, and add about a pint of acid for each two hours of working. The zinc will last about a week. The saturated acid should be drawn off after each usage.—R. A.

**Fastening on Bristles.**—A. H. (*Nottingham*).—First pick a pair of good bristles, that is, of equal substance, and as transparent as possible; from A to B (Fig. 1), on the end of each bristle, there is a dry, glutinous substance; this is the part that is in the hide when on the animal, and is of no use to us for our purpose; it is, therefore, cut off in a slanted direction, as shown by the line across it at A. Hold the two points together, and stroke them up and down, on a piece of sand-paper, somewhat in the same way as you would use a whitewash brush, holding them between the thumb and finger, and at the same time twisting them round—this will make a nice round point to them; then, about halfway, just bend them against the thumb nail, so as to centre them both in the same place. You now have one end sharp and the other end, C (Fig. 1), bushy, of which you take equal portions between the thumb and finger of each hand, and split it down to B, as shown by A B (Fig. 2). The end of the thread is waxed, and the fine tapered extremity is placed in the crutch, as B (Fig. 3), both of which are held firmly between the thumb and finger of the left hand, the palm of the hand being towards you; then between the thumb and finger of the right hand the split part of the bristle, C, and the thread with it, is twisted towards you; and each time you want to take another sweep, hold the part C, *pro tem.*, between the little and third fingers, and when twisted just tight, twist A in the same direction, being careful not to break it. Then put A and C together, hold them between the thumb and finger of the right hand, and leave go with the left at B, and with it take hold of D, and twist that in the same way. This should give a result as shown in Fig. 4. Then at A, with a fine stabbing awl, a hole, or eye, is made in the thread, and the point of the bristle put through it, as shown at A (Fig. 5). This is drawn right through, and then smoothed from the point downwards, between the thumb and finger. This, it will be seen, is to secure the ends of the bristles, and prevent them from unplaiting. This method is called plaiting. There are other ways, but this is by far the best, for stitching.—W. G.



**Overhead Motion.**—LATHE AMATEUR.—If you want a good and efficient overhead arrangement for your lathe, the following diagram may furnish you with an idea of how to go about it, and I would advise you to read it in conjunction with what was said to J. E. J. (*Portsmouth*) upon this same subject in WORK, No. 12, p. 190. A is the top of lathe bed; B, pulley to which cutter is attached; X shows that the position of these pulleys may be adjusted to suit position of slide-rest.—ED.



Overhead Arrangement for Lathes—A, Top of Lathe Bed; B, Pulley to which Cutter is attached; X, showing that the Position of these Pulleys may be adjusted to suit Position of Slide-Rest.

**Foot-Blower.**—R. H. E. (*Blackburn*).—The bellows with a reservoir is preferable to a fan-blower when worked by foot, because temporary suspension of the action of the foot does not stop the blast, and a bellows treadle is easier to work than a crank treadle. You will require special leather and wood to make the blower, and will find it a troublesome job—at least, that has been my experience in making a similar arrangement for experiments on sound. It would probably be cheaper to buy one. Messrs. Alldays and Onions, of Birmingham, supply all kinds of blowers and bellows. You might have a fan-blower fitted with a reservoir, but there is this disadvantage: a fan is not a positive blower; when the reservoir pressure exceeds that in the fan, you are wasting power in grinding wind.—F. C.

**Emery Wheels.**—NO NAME (*St. Leonards*).—Emery wheels are made of emery of various degrees of fineness consolidated under pressure with a suitable cementing material. For the actual composition I must refer you to the makers, though I am not sure they would make public their methods. In use emery wheels are run at a surface speed of from 4,000 to 4,500 feet per minute. When used for sharpening small tools, they should be used with water.—F. C.

**Steel Tubing.**—A. N. H. (*No Address*).—I do not know of any works where solid drawn steel tubing of the size you require is made. The thickness to stand a working pressure of 60 lbs. is theoretically $\frac{1}{50}$ in., but of course you cannot practically use the metal so thin. Your best plan would be to make the boiler of sheet copper about $\frac{1}{8}$ in. thick, riveted and well brazed together; then, as your firebox is of copper, the expansion and contraction under variations of temperature would be equal, and there would be less liability to leak. You might get an electro-deposited copper tube of the diameter you require.—F. C.

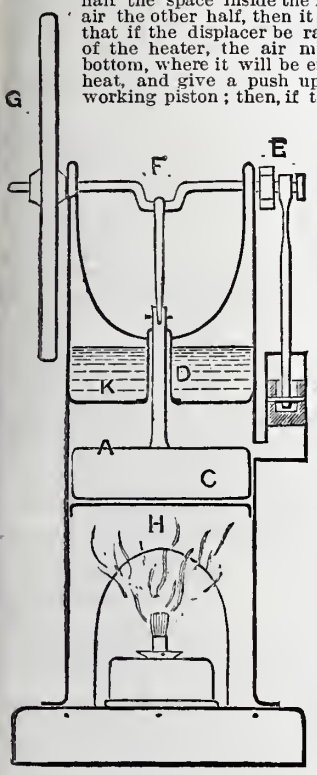
**Four-Jawed Chuck.**—G. H. A. (*Clapham*).—I do not know of any substitute for the four-jawed chuck, but if you call at Messrs. Grimshaw and Baxter's Stores, Goswell Road, E.C., you will most likely find something to suit you. If you are likely to be disheartened in so small a matter as making a model engine, I should advise you not to commence it. You can buy one for a trifle.—F. C.

**Beam Engine.**—AXLE.—The bars B and C in your sketch form a parallel motion for the head of the piston-rod, or would if they are of equal lengths, assuming that the end of bar B nearest the piston-rod is gudgeoned to the framing. Usually the rod A has a connection for air-pump or feed-pump rods, but you do not show any such attachment. This form of parallel motion is not absolutely true, but when the rods are properly proportioned, restricts the head of the piston-rod to a motion very closely approximating a straight line. I suppose the bars are brass-bushed, and the wear of the bushes causes the rocking of the piston-rod. The dead-centres upon which the rods vibrate may also have worn out of centre. If the engine worked satisfactorily when first started, your remedy is simple: put in new dead-centres in the framing, new bushes in the bars, A, B, C, and new bearings in the piston-rod head and the strap connecting it with the beam. If the rocking of the piston-rod has long continued, the gland is most likely worn oval, in which case a new one should be fitted and the stuffing-box, if necessary, bushed. In regard to the piston-rings, you do not say of what class they are, but for the size you give I should recommend a split cast-iron ring, ¼ in. thick on the thick side and ⅛ in. on the thin side, turned to an outside diameter of 8¼ in., cut on the thin side and put in in the usual way. It might be better to put in a new piston with Ramsbottom wrought-iron rings, but whatever rings you use, round off the outer edges so that the cylinder may not be scored by them. If you had given fuller particulars as to the use of the engine, I could have given further advice.—F. C.

**Hydraulic Cylinder for Lift.**—R. S. (*Manchester*).—Some dimension must first be given or assumed. Your lift is 40 feet; if, therefore, you make your ram with a 5 ft. stroke—that is, one-eighth of the height to which 3 cwt. is to be raised—the load on the ram will be 3 × 8 = 24 cwt. The speed of the cage to lift it 40 ft. while the ram only travels 5 ft. is obtained by chains passing over top and bottom pulleys in the usual way so that there are eight lines of chain side by side. One set of pulleys may be fixed to the bottom of the cylinder, and the other set to the head of the ram; from these the chain is led away over the head pulley of the hoist and attached to the cage. In addition to the 24 cwt., an allowance must be made for friction, say, 5 per cent.; 24 cwt. equals 2,688 lbs.; 5 per cent. on this is 135¼ lbs.; total load on ram, 2,823 lbs. Now the pressure of water per square inch multiplied by the area of the ram in square inches must equal this total. If there is a high pressure service of, say, 100 lbs. per square inch, the area of ram required will be $\frac{2,823}{100} = 28{\cdot}23$ square inches, which we find, from a Table of Areas of Circles, corresponds to a diameter of 6 in. The cylinder would be made about 6¼ in. inside diameter. The supply pipe should be about 1¼ in. in diameter. Whatever conditions you have you can get at your results by the above method. If, for example, the diameter of ram is fixed at 5 in., this corresponds to 19·63 square inches area, and the pressure required per square inch will be $\frac{2,823}{19{\cdot}63} = 144$ lbs. per square inch. If the pressure is to be taken from a tank, the height of the tank in feet above the ram must be equal to the pressure per square inch in pounds multiplied by 2·31. You will see that we have found the following rule for the total load on the ram: Multiply the actual load by the height of lift, divide the product by the stroke of the ram, and add 5 per cent. to the quotient.—F. C.

**Quarter Horse-Power Steam Engine.**—A. P. S. (*Hyde*).—It is not possible to comply with your suggestion.

**Hot-Air Engines.**—W. H. B. (*Leicester*).—In these small hot air-engines there is a cylindrical box, called the heater, containing air, a fixed quantity of which remains in the box, for there is no exhaust; and this air, being alternately heated and cooled, expands and contracts, the pressure varying about 12 lbs. A working cylinder is connected with the heater; in this a piston moves, being forced up when the air is heated, and drawn down when it is cooled; the top of the piston is open to the air, and a connecting-rod fastened to a pin in the piston works the crank at the upper end. Now, we cannot very well remove the fire from the heater at every stroke of the engine, so the plan adopted is to have the fire play upon the bottom of the heater, whilst the upper part is cooled by a water jacket; inside the heater there is a loose-fitting deep piston, called a displacer, whose office it is to move the air up and down, so that it may be heated by the bottom plate of the heater, and then cooled by the water jacket at the top. If we suppose the displacer to occupy half the space inside the heater, and the air the other half, then it will be evident that if the displacer be raised to the top of the heater, the air must go to the bottom, where it will be expanded by the heat, and give a push upwards to the working piston; then, if the displacer be moved down to the bottom of the heater, the air must go to the top, where it will be cooled by the surrounding water, contract in volume, and suck down the working piston. The diagram is a sectional sketch of Seal's model hot-air engine, which, being very simple, will serve to explain the principle on which these engines work. A is the heater, communicating with the working cylinder, B, by a passage always open. C is the displacer, occupying about half of the heater; it is moved up and down by a crank and connecting-rod attached to a piston, which passes through a tube, D, which acts as a guide. E is the crank moved by the working piston; F is another, which moves the displacer, and is set at right angles (about) with the first. G is the fly-wheel. The flame of the lamp plays upon the bottom plate, H, of the heater, and some water is poured upon the top plate, K. The model will start at once on lighting the lamp, and runs at 250 revolutions per minute; it has no power, the working cylinder being so small—only ¾ in. diameter. The model costs 10s. 6d. I have one, and it runs well; perhaps if Mr. Seal sees this he will advertise his present address. The action of these engines will now be easily understood. The heater crank precedes the working crank just as the eccentric precedes the crank of a steam engine: the engine being in the position shown in sketch, the air is being cooled, and the piston of B is being sucked down. In one quarter of a revolution it will have reached the bottom, and displacer, C, will be in the middle of the heater; a little further, and there will be more air beneath the displacer, pressure will increase, and the working piston will be forced upwards, etc. It is curious to find that the air can be heated and cooled 300 times in one minute. The proportion between the space swept by the piston and displacer is important, and I obtained a greater speed by reducing the stroke of the working piston; the working crank might be made with several holes for the crank-pin, and the engine tried with different strokes till the best position has been found. It will now be seen that in Robinson's engine, instead of two cranks placed at right angles, the piston and displacer are themselves fixed at right angles and worked off the same crank, which produces exactly the same effect. The power of hot-air engines is generally rated too high. I tested one with a 9½ in. cylinder, and found that, though the indicator showed 23,716 foot lbs., say, 5-men power, the brake power was only 10,028 foot lbs., say, 2-men power. For 2-men power I should require a 9 in. cylinder, and the engine would be very bulky and heavy.—F. A. M.



Hot-Air Engine.

**Damp in Piano.**—INQUIRER.—The damp which creates the rust in the bottom part of piano rises from the floor, sometimes through damping the carpet before it is swept. I should advise you to turn the piano up, so that you may tack a piece of oilcloth or waterproof over the bottom, as sometimes there are holes where damp may enter. To clean the rust off, use a piece of leather with a few drops of paraffin oil on, and sprinkle with fine emery powder. Having done this, procure some lard free from salt, and crush some camphor, and mix them together. Rub this over the strings; this will prevent rust.—T. E.

**Japanning.**—W. P. W. (*No Address*).—You appear to have been very painstaking in your work, and certainly deserve to succeed. I regret that I cannot add anything to the information already given, unless it is to express an opinion that it is scarcely necessary to go to so much trouble over repairing jobs. I should suggest that you simply give the beams, etc., a coat of finest air-drying black japan, and lay on with a camel-hair brush where required some of Pavitt's Gold Ardenbrite, and when dry a coat of clear varnish if wished, but it is hardly necessary, as Ardenbrite will keep up colour for a long time.—R. A.

**Patents.**—S. G. T. (*Penarth*).—The writer states that, on searching the lists of applications for patents (see "Shop," p. 587, No. 141), he "found that there were about two a day for the last three months for the same kind of thing." He then asks: "Can any of your correspondents tell how we are to know that some of these applicants may not have the very same thing as ourselves, and, being before us, of course have the preference?" We can assure S. G. T. that neither he, I, nor anyone else can ascertain this until the complete specification is filed and accepted, when it may be inspected on payment of the usual fee; or he must wait until the specification is printed, every application for the grant of a patent being inaccessible to the public until the complete specification is filed and accepted. Every person making application for the grant of a patent has to take his chance as to whether a prior applicant has covered his invention. There is no way of getting over this.—C. E.

**Plain Sketches.**—T. P. (*Frodsham Bridge*).—We do not know of any work specially devoted to this subject, but there are several works which touch on it. Some years ago the Council of Education published, or authorised the publication of, books on drawing, one of which gave instructions how to sketch from the object, but we do not remember the name of the author. Spon, publisher, Strand, W.C., would no doubt have it in his catalogue books, which would assist our correspondent. We know of no better course than copying from the object itself on paper, taking care that each part is *put in the right place*, and avoiding any "artistic" performance in the work, adhering to stern exactitude, so that the result obtained is the *actual machine* on the paper, and then the dimensions of each part can be taken and put on the drawing. We learnt to do this in the manner described above, and soon acquired aptitude in the work, there being no books to help us in those days. We believe there have been some books published on the subject by the Science and Art Department at Kensington. One was written by John Maxton, a clever draughtsman and engineer, who was teacher of engineering drawing to the department, and it would most likely be found in Spon's catalogue. We do not know of anyone who would teach by correspondence, but should fancy if there are any engineering establishments employing draughtsmen near our correspondent, he might be able to arrange with some of the latter to give him instruction for an hour or two of an evening, after his work is over, for a consideration to be agreed upon between them.—C. E.

**Repairing Piano.**—CLERK.—Your letter is very explicit, and I understand what you require. If your piano has not got an iron plate to which the strings are attached, the pins are driven into hard wood, and these pins in old pianos are usually made of brass instead of iron, and when you tune the piano they often bend, and sometimes break off (I am speaking of the lower pins). The wrest pins, as you say, are probably loose. Now examine very carefully and see that the plank is not split, and if it is not, take out one of the old pins and get a size or two larger; you can obtain them from W. Hughes, 37, Drury Lane, W.C., and they will cost you 1s. 6d. a set, and if the lower pins are bending, I should replace them with small hitch pins. Count the number you require, and obtain at same place; cost about 6d. You can also get what wire you want at 1s. 9d. per lb. Do not string it with beavier wire; a size thinner would be better if for concert pitch. You ought to manage it all right.—T. E.

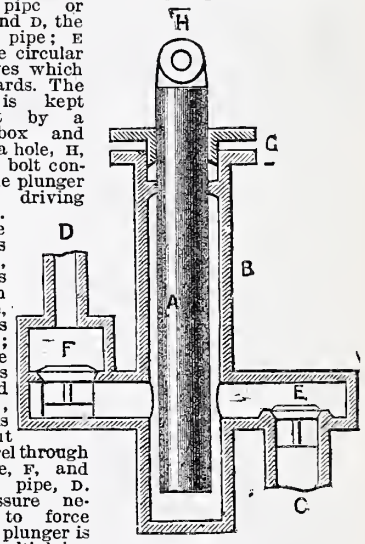
**Piano Work.**—J. M. F. (*Notting Hill*).—Your best plan would be to get an estimate from a pianoforte maker; he would be able to tell you exactly what it would cost. Try Rudd & Co., Dean Street, Soho Square.—T. E.

**Piano-Front Pattern.**—J. W. (*Wellington, Salop*).—Sorry you did not succeed in getting the patterns, but as the fret-cutters chiefly design their own, they are somewhat jealous of them. If you could get access to a piano that has a fret front, with a sheet of paper and a shoemaker's heel-ball you could rub a pattern off it by simply laying the sheet of paper on and rubbing the heel-ball over the surface. Or you could purchase a fret from the address I gave you if you send the length and width you require. Frets have given way to panels for piano fronts, although some are partially fret cut.—T. E.

**Piano Making.**—DOUBTFUL.—If DOUBTFUL will not doubt any longer, but will read my article on stringing, he will see that, instead of doubling the length of the wire, the difficulty is surmounted by increasing the thickness. The measurement, 21½ in., is correct for fourth C. I should think "Sound, Light, and Heat," by Thomas Dunmans, price 1s., would suit you; or, as you are near the People's Palace Library, you could see one there.—T. E.

**Materials for Piano.**—ANXIOUS INQUIRER.—As probably you are aware, you cannot purchase materials for piano making at one firm, as the firms who supply the trade are noted for their special line. For ironmongery, try Hughes, 37, Drury Lane, W.C; for veneers or wood, Witt and Palmer, Drummond Street, Hampstead Road, N.W.; for action, Hallpike, 213A, Mare Street, Hackney, N.E.; for keys, F. Edwards, 53, Southampton Street, Pentonville, London, N. The articles on "Piano Making" appear in WORK, Nos. 29, 32, 36, 41, 43, 46, 50, 51, which you may obtain through a bookseller.—T. E.

**Force-Pump.**—J. W. (*London*). — The accompanying diagram is a vertical section of an ordinary plunger force-pump; A is the plunger, B the barrel, C, inlet pipe or suction; and D, the discharge pipe; E and F are circular stalk valves which open upwards. The plunger is kept watertight by a stuffing-box and gland, G; a hole, H, receives a bolt connecting the plunger with the driving power. When the plunger is drawn up, water rises through the valve, E, and fills the barrel; when the plunger is pressed down, water is forced out of the barrel through the valve, F, and discharge pipe, D. The pressure necessary to force down the plunger is found by multiplying the area in square inches of the end of the plunger by the height in feet to which the water is raised, and by 0·434 lbs.—F. C.



Force-Pump.

**Piano.**—GLASGOW.—As I am not aequainted with Glasgow, I cannot refer you to any place to buy your wood, but I presume you would be able to get ordinary spruce deal, such as carpenters use, at any timber-yard or cabinet-maker's shop.—T. E.

**Piano Question.**—JOINER.—The bottom iron plate runs from the bass end, and lays on the bent side. Of course, there is no necessity for it to run further than the bent side, as there are hitch pins in the bent side. When you receive the plate from the makers, the pins, which are riveted in, will be all in their place.—T. E.

**Books on Electric Bells.**—READER OF WORK.—Mr. F. C. Allsop's book on "Practical Electric Bell Fitting" is a good work, written by a practical man who has had considerable experience in the work of bell-fitting. It is, therefore, a good book for learners. Another good book on the same subject is Mr. Bottone's "Electric Bells and All About Them."—G. E. B.

**WORK Subscription.** — JACOB. — The fourth volume of WORK will begin with No. 157, and will be, as you say, "a very good time to begin to take it in." As you are so anxious to help the publication, however, why not begin subscribing to it at once, and induce those "many fellow-workmen" of yours to do the same? Some of our subscribers even adopt the sensible plan of buying an extra copy weekly to send abroad or into the country.—ED.

**Bicycle Patent.**—C. M. (*Liverpool*).—Referring to reply to F. S. (*Kidderminster*) on page 394 of WORK, the drawing shown does not in many points agree with the description, and the information given would fail to make anyone understand what is meant or what is to be gained by the arrangement. The inventor seems to aim at gearing up an ordinary front-driving bicycle by means of a gear similar to the Rob Roy tricycle, made long since by the Zephyr Cycle Company. With them the gear is simplicity itself; in the reply referred to it is anything but simple or clear, and Fig. 2 of the diagrams is not correctly drawn. I am unacquainted with either the address of the inventor or the number of the patent.—A. S. P.

**Work Volume.**—F. R. W. (*Mildmay Grove, N.*).—The third volume of WORK commenced with No. 105.

**Watch Jobbing.**—CONSTANT READER.—As far as I am aware, there is nothing to prevent you from calling yourself a watch jobber because you have not served your term of apprenticeship; but as to going in for examination for a certificate, I am afraid that it would be useless unless you are very well up in theory and practice, which I am afraid you are not if I may judge from your letter, and therefore I think it would be a guinea spent needlessly, although, could you pass, I believe it would be a good thing; and I should like to see every jobber, watch and clock, go in for the examination: it would be better for themselves, for their employers, and for the owners of watches and clocks, as ninety-nine out of every hundred watches and clocks are, in my opinion, "butchered" up instead of wearing out. Now, as to the verge watch. When the nose of the potance has been filed away to let the wheel up as close to the verge as it will go, and the follower pushed up to keep it, and still it trips, without giving sufficient impulse to the verge, the only thing that is to be done is to put a new balance wheel ('scape wheel), broader in the band, so as to reach the verge pallets; when this is done it usually wants a new dovetail put to the potance, and often a new follower as well, but these you could easily fit up yourself. For a new wheel you must send to the tool shops, say, Grimshaw & Co., Goswell Road, Clerkenwell, London, who will put a new one for about 9d. or 1s. outside.—A. B. C.

**Fairy Bells.**—W. L. (*Hull*).—See reply to CORKONIAN on page 572, No. 140, which will give you full particulars concerning fairy bells and their construction. Following out the suggestion of the Editor, I give the cost of material, quoting from the list of Chilvers & Co., Norwich. Wrest pins, 6d. per dozen; music wire, 4d. per oz. ring any size. As, however, at least six different sizes are required for bells of twelve strings, Chilvers & Co., supply the strings with eyes already turned at 1s. per dozen, and a whole set of materials—wood for baseboard, sides, blocks, cover, together with screws, wrest pins, and wire—may be had for 4s. 6d. —R. F.

**Photographing and Mounting.**—J. McB. (*Tain*).—The photographs you require are taken by almost any good photographic firm, and will be mounted as desired. There is nothing outside ordinary portrait work indicated. If you already have the photo *unmounted*, all the photographic dealers supply the cards with sentences suitable for Christmas printed thereon. Marion, Soho Square, W., Fallowfield, Charing Cross Road, and Adams, Charing Cross Road, W.C., all keep them. Percy Lund & Co., Bradford, is also a good firm for them. See also our advertisement pages.—D.

**Re-cementing Achromatic Lenses of Opera Glass.**—MELITA.—The lenses forming the achromatic combination of your opera glass require to be separated and re-cemented together again with Canada balsam. This can be done with every chance of success if you carefully follow the instructions contained in the reply to A LOVER OF WORK (see No. 58, page 98, of WORK). You will not be able to doctor up the silvering on your looking-glass; it will require to be re-silvered after the old silver has been carefully cleaned off. The process would occupy too much space to be located in "Shop." Your work on "The Antiquities of Athens" is, without doubt, of value, but to ascertain the exact worth you should address your inquiry to a paper such as the *Athenæum*.—C. A. P.

**Cold Lacquor.**—J. H. M. (*Liverpool*).—It is not much use an amateur trying to make small quantities of lacquer. Leaving out the probability that you would spoil it in the making, it would be more expensive than buying it. If you want a good colour lacquer, I can strongly recommend the lacquers sold by the Frederick Crane Chemical Co., Birmingham. They will send you a sample 1 oz. bottle for 1s., either colourless, gold, or antique brass. See also WORK'S advertising columns.—R. A.

### III.—QUESTIONS SUBMITTED TO READERS.

**** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Oil Stone.**—A. E. M. (*Cheshire*) writes:—"I shall be glad if anyone will tell me through 'Shop' whether there is any way of softening an oil stone. I have one which to all appearances looks a good stone, but on attempting to sharpen a tool on it, it scratches instead of having a nice working surface. If anyone can tell me what to do to alter it, I shall be greatly obliged, as it is nicely mounted in case, and will save expense of buying another, as I am told they are expensive."

**Inlaying.**—J. T. S. (*Sheffield*) writes:—"Can any of 'ours' help me with information *re* inlaying wood by aid of frot machine? How are the necessary threading holes hidden? Any hints or reference to any work or article on the subject will be gratefully received."

**Staining and Varnishing.**—J. T. S. (*Sheffield*) writes:—"What is the best work on these as applicable to amateur requirements?"

**Overshot Water Wheel.**—F. T. C. (*East Finchley*) writes:—"Will some practical correspondent give the dimensions for an overshot water wheel which will lift to a height of 10 ft. by means of an endless strap and buckets enough water to supply a ¾ in. or ½ in. pipe? The supply pipe is 1 in. bore, and there is 2 ft. pressure of water."

**Carpentry Kit.**—C. H. J. (*West Bowling*) writes:—"I should be glad if in some future number of WORK some generously minded reader would kindly give a list of the tools, etc., which an amateur should possess before attempting the manufacture of household furniture, or, generally speaking, 'cabinet making.' I have no doubt that there are many others besides myself who have just recently commenced taking in WORK, and are wishful to put to a practical use some of the valuable hints which are given us in WORK. A list such as I have asked for above, with probable cost of same, would, I believe, be read with a great deal of interest by many of us novices."—[Some brother "chip" will doubtless give you the assistance you ask for.—ED.]

**Benares Brass Work.**—SLIEV DONARD writes:—"I shall feel obliged for information as to cleaning above. The brass is covered with punched patterns, and red, green, and black enamel. I have tried lemon and hot water, but the brass does not keep bright long. Has sea air any effect?"

### IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**White Metal.**—EDDIFRA writes, in answer to L. S. L. (*Kirkcaldy*) (see p. 622, No. 143):—"You do not state what kind of white metal. There are numerous alloys. If you refer to Knight's 'Dictionary of Mechanics,' p. 63, Vol. I., you will find thirty-two different alloys, all of which are under the heading of white metal, such as pewter, Britannia metal, Parisian white metal, German silver, etc. I have sent a few receipes:—Pewter, 6 parts copper, 112 tin, 2 zinc, 16 lead. Hard Pewter: 4 parts copper, 192 tin, 16 antimony. Britannia metal: 1 part copper, 1 tin, 2 antimony. Another Britannia metal: 4 parts tin, 4 antimony, 4 bismuth, 4 brass. Parisian white metal: 69·8 parts tin, 5·5 zinc, 19·8 nickel, 4·7 cadmium. German silver: 20 parts copper, 16 zinc, 3·4 nickel. Best German silver: 20 parts copper, 8·10 zinc, 5·6 nickel. If I knew what you wanted them for, I perhaps could send you better receipes."

**Polishing Vulcanite Pipe Mouth-pieces.**—W. L. F. (*Dublin*) writes, in reply to C. H. C. (*Manningham*) (see p. 622, No. 143):—"First take all file marks, scratches, etc., out with very fine emery paper; then polish with a lathe, using a circular buff, with rottenstone and oil; finish off with a soft cloth, using rouge and oil. Take care not to spoil the vulcanite by making it too hot. If C. H. C. has not a lathe, he may glue a piece of soft leather or felt on a flat piece of wood, and rub the work with it, putting the rottenstone and oil on the felt."

**Measurement Reckoner.**—J. M. S. (*Hull*) writes, in reply to J. G. (*Bradford*) (see p. 574, No. 140):—"You should get the 'Tradesman's Ready Calculator,' published, I think, for about 6d. by Messrs. Routledge & Sons, the Broadway, Ludgate Hill, London. It is a splendid little book, and will suit all purposes."

**Ivory Tablets.**—W. F. H. (*Dagmar Terrace, Islington*) writes, in reply to SEA GULL (see p. 574, No. 140):—"I am a wholesale maker, and supply nearly all the camera makers in London."

**Lapidary Work.**—H. S. G. (*Fulham, S.W.*) writes, in reply to SPES MEA (see p. 542, No. 138):—"This is dealt with on p. 173, No. 81 of WORK."

**Ready Reckoner for Timber and Glass Trade.**—M. (*Bishop Auckland*) writes, in reply to J. G. (*Bradford*) (see p. 574, No. 140):—"The 'Complete Measurer,' by R. Horton, published by Crosby Lockwood & Co., treats of the measurement of timber and glass. 'Haworth's Practical Timber Measurer,' price 1s., post free, from 19, South John Street, Liverpool, is also a good book."

**Wooden House.**—M. (*Bishop Auckland*) writes, in reply to OLD CHIP (see p. 590, No. 141):—"Try W. Whiteley, Westbourne Grove, Bayswater, London."

**Open Sailing Boat.**—T. M. (*Liverpool*) writes, in reply to G. A. (*Hornsey, N.*) (see p. 606, No. 142):—"The best dimensions he could have for a sailing boat 19 ft. long are: 5 ft. 3 in. beam amidships, 2 ft. 2 in. deep amidships, and 6 in. deeper at stem and sternpost, which will be 2 ft. 8 in. This gives a sheer of 6 in. If he is going to build a square-stern boat, the width of stern will be half the beam—2 ft. 7½ in.—and the tuck in sternpost to allow stern to fit on will be 1 ft. 6 in. deep. All depths to be taken from top edge of keel. The stem should be made of English oak or elm, as with these he can get the grain right in the round at the foot of stem. The keel, gunwale, sternpost transom, and timbers could be made of American oak. The planking should be either larch or yellow pine."

### V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—T. C. (*Liverpool*); H. D. S. (*Uxbridge*); A. J. C. (*Carlisle*); J. W. (*Upper Norwood*); C. D. (*Bury St. Edmunds*); E. C. S. (*Bristol*); J. S. H. (*Cheetham*); ELECTRA; G. H. (*Oldham*); R. M. T. (*Cornwall*); J. M. M. (*Bristol*); A. R. (*Ottawa, Canada*); F. H. F. (*Homeland, U.S.A.*); H. R. (*Kidderminster*); T. J. (*Preston*); W. S. (*Carbrook*); J. W. B. (*Huddersfield*); E. J. (*Borough, S.E.*); ADMIRER OF "WORK"; G. S. W. (*Dewsbury*); J. W. (*Loughborough*); TREGER; LOVER OF "WORK"; ZINCO; TELEGRAPH; L. H. (*Brighton*); V. L. (*Bayswater*); G. P. D. (*Aberdeen*); A. H. B. (*Petworth*); H. C. F. (*Great Bedwyn*); J. A. J. (*Morriston*); A. H. Manningham; S. M. A. D. A. (*Tunbridge Wells*); G. C. (*Penälleon*); W. S. (*Appleby*); W. W. (*Forest Gate*); J. W. (*Glasgow*); A. H. P. (*Lewisham*); C. E. L. ## *SALE AND EXCHANGE.*

**Victor** Cycle Co., Grimsby, sell Mail-cart Wheels and Parts. [11 R

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath. 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repousso Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). [2 S

**¼ h.-p. Horizontal Steam Engine**, as described in the pages of WORK by F. A. M. All the castings, forgings, and other materials required in the construction of these excellently designed Engines, may be had from H. MILNES, Ingleby Works, Bradford. Prices on application.

**The Buyers' Guide** to the best Books on Mechanical Subjects, with table of contents, price 6d. In cloth, 1s. 6d. —Published by BRITANNIA Co., Engineers, Colchester.

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of three thousand new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Machinery wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send two stamps for Register to Box 505, BRITANNIA TOOL FACTORY, Colchester. [7 R

**Try Bolton,** Burmantofts, Leeds, for Fretwork Materials. Lists free. [8 R

**For really good,** cheap, Mechanical, Electrical, Optical, Chemical, Photographic Apparatus and Models, consult CAPLATZI'S nine 2d. Catalogues.—Chenies Street, W.C. [10 R

**Fretwork Designs.**—Six magnificent animal brackets, 1s. 1d.; sample, 3½d.; six large comic, 1s. 1d.; 12-inch steel saw frame, 9d., post free.—TAYLOR'S Fretworkeries, Blackpool. [12 R

**Castings, etc., Iron and Brass.**—GODDARD, Gosforth, Newcastle-on-Tyne. [13 R

**Paper Letters, Rubber Stamps, etc.**—Agents should apply for samples (free).—WILLCOX BROTHERS, 172, Blackfriars Road, London, S.E. [5 S

**The Saltaire Lathe,** and numerous chucks, etc., by Evans. Cost £2,000; offered at £350; immediate clearance. Several others, varying from £50 to £4.—BRITANNIA Co., Colchester. [3 S

**Electric Batteries,** bells, telephones, coils, silk- and cotton-covered wire, terminals, sundries; stamp.—F. CHARLTON, 14, Starkey Street, Stockton-on-Tees. [1 S

**Incubators.**—All fittings for Leghorn's machine of T. STEVENS, 7, Selhurst Road, South Norwood. List, stamp. [4 S

**"The Carver's Designer."**—Three sheets of full-size practical designs for wood-carving. Monthly, 1s. 1d.; post free from HENRY KUCHEMANN, 49, Woodstock Road, Chiswick. [14 R

# BEECHAM'S PILLS.

**WORTH A GUINEA A BOX.**

*A Wonderful Medicine for all Bilious & Nervous Disorders,*

SUCH AS

**Sick Headache, Constipation, Weak Stomach, Impaired Digestion, Disordered Liver, &c.**

BEECHAM'S PILLS have been before the public for half-a-century, and are to be found in every English-speaking country; they have by far the largest sale of any patent medicine in the world.

BEECHAM'S ST. HELENS LANCASHIRE PATENT PILLS.

Prepared only, and sold Wholesale, by the Proprietor, THOMAS BEECHAM, St. Helens, Lancashire. Sold by all Druggists and Patent Medicine Dealers everywhere, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each. *Full directions with each box.*

## PAINTERS!! GRAINERS!! DECORATORS!!

**The Art of Graining** is now complete, and contains 20 splendid plates. The finest example of graining ever published. Each plate is 18 x 13.

*Price in Parts, 36s. Bound, 42s.*

30 pages of Technical Instruction.

**Painted Wall Decoration.**

*2/6* The Christmas Number of the Journal of Decorative Art. *2/6*

A Perfect Manual of Design and Technical Instruction on

SURFACE DECORATION,

containing

10 LARGE SHEETS OF WORKING DESIGNS, BORDERS, DIAPERS, POWDERINGS, ETC. ETC.

(*Price 2s. 6d.; post free, 2s. 9d.*)

*For full particulars, see the November Number of* **The Journal of Decorative Art.** (7d.)

**W. G. SUTHERLAND,**
15, ST. ANN STREET, MANCHESTER.

**SIMPKIN, MARSHALL & CO., LTD.,**
317, STRAND, LONDON.

No. 912, at 2d.

Volume V. of *The Amateur* commences with the January Part, 1892; now ready. Lists 43 and 44 of designs, wood, machines, tools, and cabinet fittings free. All goods greatly reduced in price.

## THE DOUBLE-POINTED NAIL.

(*Durrans' Patent*).

**For Dowelling Joinery of all Kinds.**

INVALUABLE FOR CARPENTRY OF EVERY DESCRIPTION.

*Particularly Useful to Amateurs.*

Machine Steel cut Nails, ¾ in., 1 in., 1¼ in., 9d. per gross; 1¾ in., 1s. per gross.

Sample boxes, assorted sizes, 6d.; by post, 8d.

These Nails are a perfect protection for fence tops and trellis work, preventing the ravages of trespassers and cats.

**Malleable Iron Fence Nails.**

Sizes, 1¾ in., 2 in., 3 in., 4 in., 5 in., and 6 in., in 7 lb. bags, 3s. 6d.; per cwt., 55s.

***Durrans' Patent Nail Syndicate, Limited,***
**43 and 44, Upper Baker Street, London, N.W.**

## THE POLYTECHNIC SERIES.

Consisting of Practical Illustrated Manuals specially prepared for Students of the Polytechnic Institute, Regent Street, London, and suitable for the use of all Students.

**Forty Lessons in Carpentry Workshop Practice.** Cloth gilt, 1s.

**Practical Plane and Solid Geometry,** including Graphic Arithmetic. Vol. I. ELEMENTARY STAGE. Cloth gilt, 3s.

**Forty Lessons in Engineering Workshop Practice.** 1s. 6d.

**Technical Scales.** In set of Ten in cloth case, 1s. per set. Also on celluloid, in case, 10s. 6d. per set.

**Elementary Chemistry for Science Schools and Classes.** Crown 8vo, 1s. 6d.

**Building Construction Plates.** A Series of 40 Drawings. Cloth, 10s. 6d.; or copies of any Plate may be obtained in quantities of not less than one dozen, price 1s. 6d. per dozen.

## FOUR HUNDRED POUNDS

WORTH OF FRETWORK DESIGNS.

J. H. SKINNER & CO. have now ready for delivery 8,000 of their Tenth Annual Catalogue of Fretwork, Carving, and Photographic Apparatus, including Designs, Fancy Woods, Treadle and Hand Machines, Frames, Saws, Drills, Planes, Carving Tools, Bevelled-edge Mirrors, Ornaments, Fasteners, and all other requisites; also Swiss and Chinese Wood Carvings, Magic Lanterns, Skates, Fancy Pocket Knives, and Scissors; Amateur Joiners' Benches and Tools; and their new **CELESTIAL ENAMEL** for decorating wood, glass, metal, earthenware, etc., the best and cheapest enamel in the market, including 54 different coloured specimens of the Enamel itself, beautifully mounted on a handsome recessed card (this card alone is well worth the amount charged for Catalogue). The above described Catalogue of 60 pages quarto, with 600 illustrations beautifully lithographed, SENT POST FREE ON RECEIPT OF FOUR STAMPS. With each Catalogue we will include, **GRATIS, One Shillingsworth of Fretwork Designs,** selected by us from our stock. As each Catalogue costs us, with postage, only a fraction less than Sixpence, our customers will thus get in value ONE SHILLING AND SIXPENCE FOR FOURPENCE.

The Season being already so far advanced, we have decided to make this extraordinary offer, in order that our Catalogues may be distributed AT ONCE, trusting to the profit on future orders to recoup us for the loss on Catalogue.

**BEGINNER'S OUTFIT,** consisting of 12-in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient Planed Fretwood and Full Instructions, price 2s. 6d., post free. 6 ft. assorted Planed Fretwood, 2s. 6d.; 12 ft., 4s. 3d., post free. Book containing 12 sheets full-size designs, 1s. Good Fretsaws, 1s. 4d. per gross.

**J. H. SKINNER & CO., W Department, EAST DEREHAM.**

*Kindly mention this paper when ordering.*

## TO AMATEUR AND PRACTICAL WORKERS.

Every kind of Foot and Steam Power Lathes, Drills, and Machine Tools. Twist Drills and Emery Wheels.

Lathe Castings from 3½ to 18 in. centres. Model Engine Castings, Tool Steel, Chucks, etc.

Fretworking Machines, Woods, Tools, and Designs at low prices. All kinds of Mechanical Work Done.

ILLUSTRATED PRICE LISTS ON APPLICATION.
**JOHN AARON, 10, Gaol Lane, Halifax.**
SHOWROOM: 8, COW GREEN.

Part 1, ready JAN. 25, price 3d., of

## The Child's Bible and Child's Life of Christ.

WITH

*SEVERAL HUNDRED LARGE ILLUSTRATIONS.*

These Magnificent Works, which have already had a combined circulation of upwards of 200,000 copies, will now be issued at a price which will place them within reach of the humblest homes in the land. This Popular Edition is exactly the same as the Original Edition in regard to type, matter, and Illustrations, whilst the price charged will be less than half that at which the works have hitherto been obtainable in Serial form.

# WORK

## An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 150.] SATURDAY, JANUARY 30, 1892. [PRICE ONE PENNY.

Fig. 3.—Grotesque Animal Interlacement: "Book of Kells."

Fig. 2.—Border from St. Dympna's Crosier.

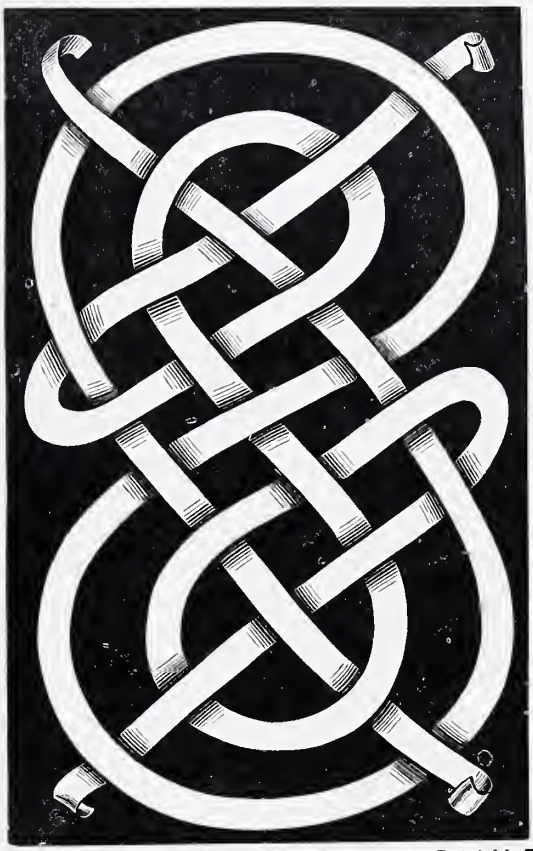

Fig. 1.—Interlaced Ribbon Work from Shrine of St. Patrick's Bell.

Fig. 5.—Interlaced Ribbon: Ardagh Chalice.

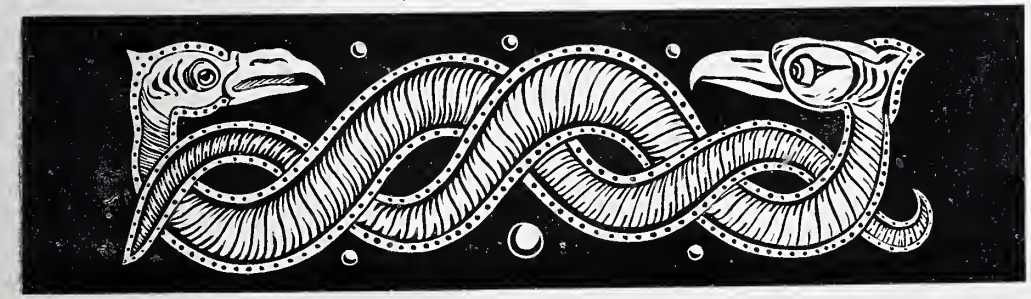

Fig. 4.—Tara Brooch.

SIMPLE EXAMPLES OF KELTIC ORNAMENT.

Drawn by Opifex.

## SIMPLE EXAMPLES OF KELTIC ORNAMENTS.

BY OPIFEX.

In mediæval times Irishmen were wonderfully skilled in the art of decoration, especially in the illuminating of manuscripts. They were also very "cunning workmen" in bronze, silver, and gold, and must have been far superior to their posterity of to-day in powers of eyesight and, I think, also in patience.

In intricacy of design, accuracy in detail, and faithfulness in workmanship, the specimens of Keltic or Irish art which survive surpass anything produced by others in any country or period, ancient or modern.

To one who has never before seen any of these original works, a first inspection is simply amazing—assuming, of course, that they possess an appreciative sense. A page of the "Book of Kells" (seventh century), for instance, affords an opportunity for days of patient scrutiny, if one desires to follow the labyrinthine workings of the scrolls, knots, etc., executed by hands which have been at rest for a thousand years.

The chief characteristic of the Keltic style is interlacement, whether of simple "ribbons" (Figs. 1 and 5), grotesque animals (Fig. 3), or plant forms—the last being rare—or combinations of these.

One example will serve to give the reader some idea of the intricate nature of the designs. On a page of the "Book of Armagh" (A.D. 805, cir.) may be seen spaces of less than three-quarters of an inch long, by about half an inch wide, upon which designs are drawn containing 160 interlacements, of a fine ribbon pattern, and the most patient and searching examination with the aid of a powerful magnifying glass will fail to detect a single mistake or irregularity in the interlacing.

It has often struck me that, by means of enlargement and slight modification, some of these patterns might be turned to good account for various purposes of decoration, or be found most useful for fretwork, leather work, wood carving, repoussé work, or, in fact, any work of an artistic kind; and I have lately taken some note sketches from ancient specimens of pure Keltic work, and having found them most suitable and effective for some of the purposes just mentioned, I here give a few of the simpler examples, and hope, with the Editor's approval, to contribute some of a more elaborate nature at a future date.

The centre panel (Fig. 1) is a very simple example of ancient interlaced "ribbon," or strap-work, and is taken from the "shrine" of the bell of St. Patrick—a beautiful specimen of pure Keltic workmanship, made by an old Irish goldsmith, named "Cudulig O'Innainin, and his sons," about the year 1091, A.D. The body of the shrine is of brass, on which are riveted silver plates, gilt and ornamented with gold knot-work, and further enriched with gems and crystal.

The present example may prove suggestive for designs for various uses, but especially for fretwork, to which this class of pattern lends itself admirably. It is also an effective style of ornament for embossed leather work.

The border (Fig. 2) dates from the seventh century, and adorns the crosier, or rather, the pilgrim staff, of a certain pious princess and saint, named Dympna, who once lived in co. Monaghan, but having for some reason fled to Belgium, she founded a religious house and church, which still bears her name, at Ghent, where she has always been regarded as the patroness of the insane. This design, though rude in conception, is not without some weird grace, and might, if modified and improved, form a good border for repoussé work.

Fig. 3 is an example of a grotesque animal interlacement, and is enlarged and adapted from a minute design occurring in part of a large initial letter in the "Book of Kells," now in the library of Trinity College, Dublin. Reversed and duplicated, this design will be found suitable for various kinds of art work.

Fig. 4 is, I confess, not beautiful, nor is it exactly true to any original, but was suggested by a very minute design upon the "Tara brooch," with which many of my readers are doubtless familar, and which is an object of great interest to all antiquarians, as it is a gem of ancient metal work, and is certainly of great antiquity, although there is no distinct clue to the date of its manufacture. The design is suitable for repoussé, and when enlarged, forms an effective panel.

Fig. 5 is another specimen of interlaced ribbon work taken from one of the most precious and interesting examples of Keltic metal work, the Ardagh chalice, dating most probably from the close of the seventh century.

## HOW TO SECURE COPYRIGHT IN DESIGNS.

BY CHARLES KELSEY.

Marking the Finished Articles—Searches for Designs—Extent of Copyright—No Renewals—What Constitutes an Infringement—Fraudulent and Obvious Imitations—Penalties—Inspection of Expired Designs — Exhibition Recommended — Conclusion.

In my former papers I have brought the reader up to that point when he gets his certificate of registration issued to him. There yet remain certain other points, which I will deal with in this concluding paper.

*Marking the Finished Articles.*—The Act directs that the finished goods to which a registered design has been applied, should, before delivery on sale, be marked in a certain way—those which belong to classes 1 to 12 should be marked "Rd.," and the number given by the Office upon registration as "Rd., 15423"; those in Classes 13 and 14 should bear simply the mark "Regd." If this is not done, the registration will be invalidated, unless the proprietor can show, to the satisfaction of the Court, that he took all proper steps to ensure the goods being so marked.

This regulation is to let the public see that the design is registered, so that no person could allege that he was not aware of the fact; for, by examining an article, any person can see whether it is registered or not. This marking is sometimes difficult to perform on some articles, from various reasons; but then labels or tickets should be used, either attached to or connected in some way with the article. In Class 13—*i.e.*, the textile piece goods class—the mark is usually put only upon the end of a long roll of the material, so that in these cases many pieces of even yards in length might be cut off, and circulated amongst the public, without bearing any indication that it is a registered design, which is not open to imitate or reproduce.

*Searches.*—If, in such cases, it is proposed to reproduce a design—perhaps an order has been received for execution—and there is reason to think it is a registered pattern, this can be decided by sending to the Office a Search Form, "N," costing 5s., and two representations of the design. The Comptroller will institute a search, and inform such a person whether the design is one in which a copyright is still existing. If it is, he will give him the name and address of the proprietor, and the date of registration, so that the time the copyright has to run may be easily calculated. If the article bears a registration number or other mark, similar particulars will be sent if a copy of the mark is furnished on the same form "N."

These searches are also useful to find out if a design has been anticipated before making an application; or if an action for infringement is threatened, a search may, perhaps, reveal other designs, which would bar the threatened action by revealing anticipation. In cases where the registration number appears upon the articles, the information as to the proprietor and the date of registration may be got by the applicant himself, without paying any fee, by referring to the official journal of the Patent Office, sets of which are kept in the public library at the Patent Office; and sets are also kept at most of the public libraries in the chief towns of the kingdom.

*Copyright limited to the United Kingdom.*—The copyright granted refers only to the United Kingdom. Foreign countries have their own laws and regulations, which must be complied with before a copyright can exist in those countries. But certain rights of priority are given to the registered proprietors of this country by the International Convention, the practice for designs following, in nearly every particular, that applying to patents.

*No Renewals.*—After the expiration of the period of copyright the design becomes public property: it is open to anyone to produce or sell it, and the Act gives no power of renewal of the copyright in any case. It is not again eligible for registration, because, at this later date, it would not fulfil the conditions precedent to secure a valid registration—*i.e.*, being new or original, and not having been previously published in the United Kingdom.

*What Constitutes an Infringement.*—The Act says that the unauthorised reproduction of the design, or any fraudulent or obvious imitation thereof, constitutes an infringement, and it is also an offence to sell or exhibit for sale any articles to which the design or the fraudulent or obvious imitation has been applied, after the person so selling or exhibiting for sale has been warned that the articles in question are infringements of a registered design.

A recent amendment of the Act renders the person who causes to be applied such infringement, liable for penalties. Under the law, as it formerly stood, the greater sinner got off scot-free, whilst the person who had produced the goods on the order of someone else—such as a manufacturer producing for a merchant's order—was alone liable for damages.

Most cases turn upon the meaning of the words, "any fraudulent or obvious imitation thereof," and the question whether it is an "obvious imitation" is determined by the eye of the judge who tries the case. After hearing evidence from each side, he, as it were, puts to himself this question—Could the imitation be passed off upon an ordinary

person as the original design, say in the case of a person ordering from a sample of the original design, and being supplied with the infringement in execution of the order? If the infringement is close enough to deceive such a person, in such an instance, it would be deemed an "obvious imitation" within the meaning of the Act. In one case, a person set his designer to work to produce certain designs, which should have the same general effect to the eye as some prior registered designs which he supplied the designer with. He directed him to vary all the details, so that they could not be said to be exact copies of the registered designs, but he was at the same time to preserve the same general effect. The Courts held that these were "obvious imitations" of the registered designs, saying that if the first designs had not been brought out, the imitating ones would have had no existence.

The question of "fraudulent imitation," turns mainly upon the evidence of fraud or fraudulent action of the persons producing the imitation which is put before the Court; in some cases, this term seems to have a wider sweep than the terms "obvious imitation." A common defence to an action is to set up a counter-plea that the registered design was not new or original at the date of registration, or was published before that date, and, therefore, not entitled to be registered; and if this plea succeeds, the original action falls through, and the Court makes an order for the design to be struck off the register.

*Penalties.*—The Act says that a penalty not exceeding £50 may be claimed for every offence by the registered proprietor of the design, who may recover such sum as a simple contract debt by action in any Court of competent jurisdiction.

The registered proprietor may, if he elects to so so, bring an action for the recovery of any damages arising from the infringement.

*Inspection of Expired Designs.*—On the expiration of the term of copyright all designs are open to inspection by the public. Any person may do so, any day between the hours of 10 till 4 p.m., at the Designs Branch of the Patent Office, and copies may be taken, but a fee of 1s. for every quarter of an hour is charged. This fee acts practically as a seal of secrecy on the expired designs, and if this regulation could be abolished and the designs publicly exhibited, a very valuable mine of information would be at the disposal of the public. The patent specifications, and the registered trade marks, are open for inspection free of charge, and there seems no valid reason why the expired designs should not be treated in a like manner: No doubt, interested parties may object to their designs being publicly exhibited, after their term of copyright had expired, but they could have little real ground for complaint, as the fundamental principle of the law is, that the grant of exclusive copyright for a limited time is to be repayed, by the public having the full benefit of the design or invention after that term has expired.

In the present day, when the questions of technical education, museums, and exhibitions are so much to the front, it seems strange that this large collection of expired designs have not been utilised. The value of such a technical museum or exhibition as might be formed from the expired designs, could not be overrated, especially if developed by some experienced person, who had sufficient knowledge of technical requirements, and true notions as to the good in industrial art, to be able to winnow away the chaff and select for exhibition the true grain, worthy of being imitated, and such as would tend to the education of the students frequenting the place, and to raise the standard of excellence in industrial art and design. The value of such a museum or exhibition would be enhanced by the fact, that these designs are the actual things which are finding a sale in present-day markets. The exhibition of a collection of unique and ancient articles, such as form the bulk of our museums for the advancement of industrial art and design, is, without doubt, valuable to the designers for present-day markets, and is, of course, highly interesting from an historical point of view; but it is open to the oft-urged objection that the articles are, in many cases, totally unfit to serve as models for imitation in the present day, when the wants to be met are so different, the conditions of sale so altered, and the methods of production so totally revolutionised.

There is another point which tells in favour of such an exhibition: here the designs are ready to be used, and will cost nothing, whilst the cost of acquiring a collection of rare and unique articles is naturally very considerable. The number of designs available is also always increasing, and there seems no reason why grants of these designs may not be made to localities, in the same way as the patent specifications are granted, to furnish the local technical museums; which are now, under the fostering influences of the "Technical Instruction Act," springing up all over the country. Of course, experience would be wanted in the selector, so as to ensure localities securing what would prove most valuable to their special industries, and what would tend to develop a correct taste in the students who would take advantage of them.

The institution of such an exhibition or museum, in conjunction with the Designs Office, would be highly valued by designers generally, and, if properly brought to their notice, would be largely used, and, at the same time, would do much to popularise the Office, and bring its proffered advantages more clearly home to the class whom the law is so well adapted to benefit—the ingenious artisan, worker, or designer.

Under present circumstances these advantages are much more largely acquired by manufacturers in a large way of business—who frequently register hundreds of designs in a year—than by the individual designer, who can thus create a property in his work, and in many cases enhance its value in the eyes of the manufacturer, to whom he offers his design for sale; for an exclusive right to manufacture means cutting off competition, and ensuring a sale at a price which will yield a fair profit to all concerned.

It is my fervent hope that these papers will do something towards bringing the knowledge of the advantages which are open to all, prominently before that very wide class of workers who weekly or monthly peruse these pages. The subject on which I have been writing is one that is of the utmost importance to many readers of WORK, and if I appear at times to have been somewhat prolix and precise, I must ask indulgence on the plea that I have been desirous of leaving unsaid nothing that might be said, or should be said. I have spoken of this in the concluding paper of this series, but I may as well say that there is another to come on "Copyright in Sculpture," which was promised in my first paper.

## SPECIFICATION OF WORKS FOR ERECTION OF A PAIR OF COTTAGES.

BY W. BENNETT.

### Designs for a Pair of Cottages.

The designs submitted are for a pair of cottages; they are designed for the purpose of meeting the requirements of the many readers of this valuable paper who write asking for a design for a pair of cheap and substantial cottages, and whose wants, I trust, will be satisfied with what I now bring under their notice. In the illustrations it will be found that the cottages are economically and comfortably arranged. They consist of a parlour, kitchen, scullery, pantry, etc., together with a small porch, which give the buildings an architectural effect.

It will also be seen, by referring to the chamber plan, that there are provided three bedrooms to each cottage. The mullion windows are to be provided with 1½ in. sashes, to open inwards. You will see by referring to my specification what materials I would advise in their erection. I estimate the cost of the cottages, with 9 in. interior walls and 14 in. exterior walls, to cost the sum of £300; if 4½ in. walls be used for the interior and 9 in. for the exterior walls, their cost will be greatly reduced—from £300 to £240.

### Excavator.

*Trenches.*—Make perfectly level the bed of all trenches for footings and consolidate the earth about the same, and against all drains, walls, etc.

*Concrete Foundations.*—To make an artificial foundation to the entire buildings, the same to be composed of one part of the best fresh quickstone lime to six parts of unscreened coarse stone ballast, mixed thoroughly with each other.

### Specification of Works—Brickwork.

*Brickwork.*—The whole of the exterior brickwork to be of the best red pressed bricks, first quality, laid on mortar, compounded of one-third well burnt stone lime and two-thirds of clean sharp sand, free from salt. The brieks are to be properly bonded together in old English bond, and no four courses to rise 1 in. beyond their collective height.

*Brickwork, Interior.*—The whole of the interior brickwork to be the best clamp bricks, hard, square, and free from shakes and cracks, and to be laid on mortar, as described above.

*Damp-proof Course.*—Lay throughout the length and thickness of walls and jambs a course of pitch and tar well boiled, or a layer of roofing felt well soaked in pitch and tar, the same to be ¼ in. in thickness, to prevent the damp from rising.

*Gauged Arches.*—All front and back windows to have the best gauged arches, abutting on proper skew-back, the soffit and reveals to be 4½ in., all outer openings to have plain axed and cambered arches closely set and pointed in cement.

*Brick Strings and Cutting.*—Properly form the string courses, fascias, breaks, recesses, etc., shown by drawings (cutting and rubbing such of the work as may be moulded), neatly splaying angles, plinths, etc.

*Fireplaces, Flues, and Stacks.*—Properly form all fire openings, with camber arches over the same, and trimmer arches where required for front hearths. Carefully gather in the chimney throats and carry up flues of not less than 14 in. by 10 in. in the clear, well pargeted. The stacks to be carried above roof to the height shown on elevations,

with salient courses, etc., and properly fix the chimney tops hereafter described.

*Chimney Bars.*—Put chimney bars of wrought iron, 2½ in. by ½ in., and 18 in. longer than the chimney opening, properly caulked at the ends.

*Bedding and Pointing.*—To bed in mortar all the bond timber, plates, lintels, woodbricks, templates, stone, and other work requiring to be set in the brickwork. To

vide and fix all proper junctions, syphons, bends, and traps, where requisite.

*Jobbing.* — Attend upon stone-masons, joiners, plumbers, etc., aiding and making good after them, and perform all jobbing necessary to perfect completion of works.

### STONEWORK.

*Doorsteps.*—To put to all exterior doorways two 12 in. by 6 in. plain solid tooled

be not less than 2 in. Properly cut double hips and eaves, and cut heading course.

### PLASTERER'S WORK.

*Plaster Walls.*—Cover all the brick walls with simply one coat of paint cement: this cement to be worked to a fine surface with a wood float and carefully applied.

*Ceilings.*—Lath, lay, and float all ceilings with best lime and hair plaster.

Fig. 1.—Front Elevation.

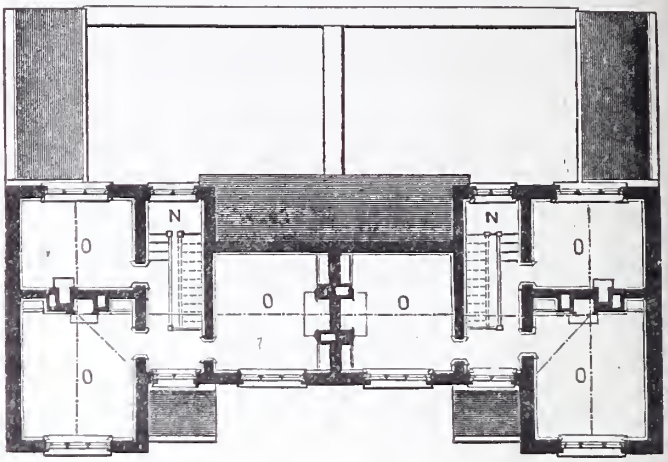

Fig. 4.—Chamber Plan.

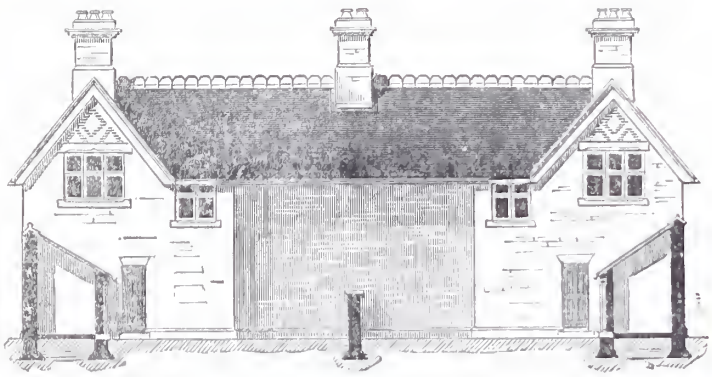

Fig. 2.—Back Elevation.

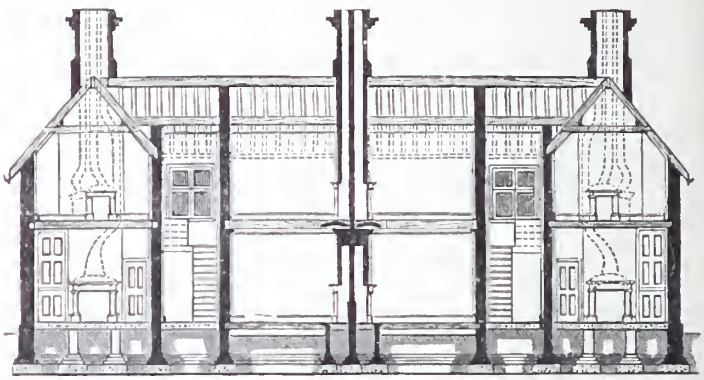

Fig. 5. — Longitudinal Section along Line C D in Fig. 3.

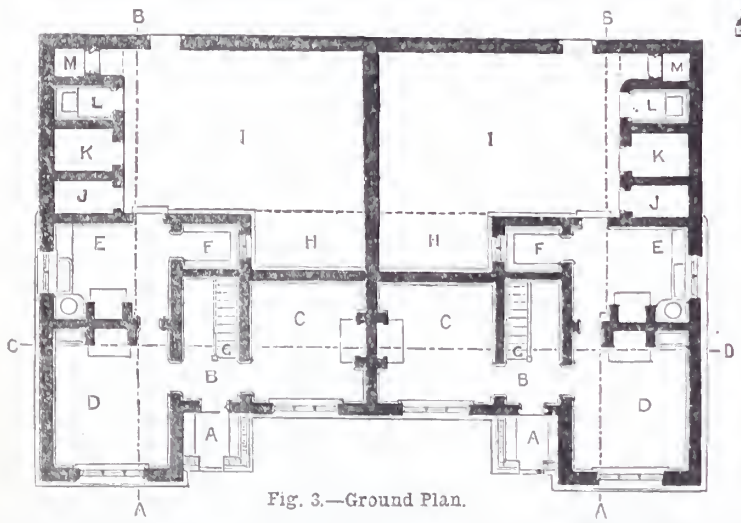

Fig. 3.—Ground Plan.

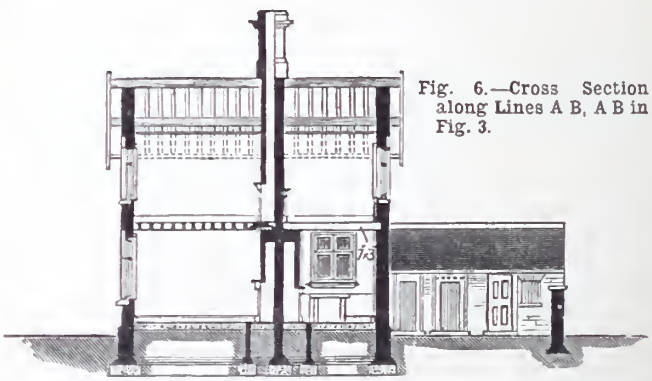

Fig. 6.—Cross Section along Lines A B, A B in Fig. 3.

bed in and point round with lime and hair mortar all door and window frames, and back up and fill in with solid brickwork.

*Encaustic Tiles.*—Pave the kitchen and passages with 6 in. Maw's encaustic tiles laid on a 4 in. bed of concrete, the tiles to be well grouted over with cement when laid.

*Glazed Earthenware Pipes.*—Provide and lay drains with glazed stone earthenware socketed pipes, free from cracks, the drain to be laid to a fall of 2 in. in 10 ft., and jointed with tarred gaskin or cement. Pro-

steps of Whitby stone, the same to be 6 in. longer than the opening.

*Chimney Stacks.*—The chimney stack to be capped with a 6 in. stone, splayed at the top.

### SLATING.

*Slating.*—Cover the roof with good scantle slates on sound heart of oak or fir, double laths and oak pins; no slate to be less than 20 in. by 10 in., and the whole to be well plastered against the pin with lime and hair mortar, the lap of upper slate over lower to

*Backing.*—To back all plinths and architraves with lime and hair plaster.

*Angles.*—To form all angles and corners with Keen's cement.

### CARPENTER'S AND JOINER'S WORK.

*Sundries.*—Provide and fix all required scaffoldage, centring, turning pieces, beads, stops, fillets, tilting fillets, backings, blocks, cradlings, firrings, bearers, and all such like required for erection of dwellings.

*Bond Lintels.*—Provide all necessary

wood bricks and templates of sound Memel or red pine, free from shakes, sap, or dead knots, also lintels of Memel or pine over all window heads. All lintels used must have a vertical depth of 1¼ in. for every foot of opening.

*Ground Joists.*—All ground joists to be of sound pitch-pine, 4½ in. by 3 in., and 12 in. apart, and to be secured to wall plates, 4½ in. by 3 in., and to sleeper walls.

*Ceiling Battens.*—The joists of upper floor to have ceiling battens 1½ in. by ¾ in., and put 12 in. apart.

*Roof.* — The roof over building to be supported by trusses, as shown by the section, these trusses to be no more than 8 ft. apart; all scantlings to be of red wood, properly bolted together where required. The roofing spars to be 1½ in. by 2 in., and 12 in. apart.

*Windows.*—Provide all windows with mullions and sashes to open on pivots or hinges, also window-boards and architraves, and fix same.

*Projecting Eaves.*—Provide and fix a necessary woodwork to form projecting eaves, the fascia to eaves to be 7 in. by 1½ in., with bead run along under part.

*Floors.*—Cover all floors, except where otherwise described, with red deal floor boards ½ in. thick.

*Doors, etc.* — Provide and fix all doors, plinths, joists, lintels, seats, and all bond timbers where required in erection of dwellings, and make good after other trades for completion.

### Plumber and Glazier.

*Windows.* — Glaze all windows with 24 oz. glass, properly secured to sashes by beads, the upper part of the sashes to be glazed in small squares with leads, as per drawing.

*Eaves Spout.*—Provide and fix 6 in. by 4 in. eaves spout securely fixed to fascia.

*Fall-Pipes.*—Provide and fix all fall-pipes where necessary, with proper bends and heads to same.

### Painter's Work.

The whole of the outside work to have four coats in oil and turps, plain colour; the inside to have three coats, exclusive of priming.

[The foregoing paper has been prepared in accordance with the wish of a correspondent, who asked for plan, etc., of a pair of cottages.—Ed.]

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

Pointing a Rope—Mainstay—Shear-Legs—Hammock Clews—Stern Ladder—Mat Making—Conclusion.

*Pointing a Rope* is done partly to prevent it from untwisting, and partly to make it go more readily through a block or hole. Fig. 135 gives one manner of doing this. The rope is first unlaid for the necessary length, and the strands reduced gradually. They are then laid up again. The ends are finally whipped with small twine. If the end is not strong enough without it, a piece of stick is inserted to stiffen it. Sometimes a "becket"—that is, a piece of small line with an eye at the end—is put into the end and whipped over to secure it, as in the engraving. Fig. 136 gives another more elaborate way of doing the same thing. The rope is first unlaid, and a stop put on it where the unlaid part commences. As many yarns as are required are taken out and made into nettles by twisting together the two halves of different yarns. The remainder of the yarns are scraped down taper with a knife. Half of the nettles are turned back on the standing part of the rope, and the other half allowed to lie on the scraped part. Two or three turns of twine are hitched round the division of the two sets of strands, and the nettles laid backwards and forwards, the weft being passed each time, as described in making the fender (Fig. 131). The end is usually whipped and a seizing put on the upper part, which is snaked, as shown in the figure, by passing twine diagonally under and over the outer turns of the seizing alternately—that is, if it comes out over the upper turn, it will go under the bottom one, under the top, and so on until it is finished.

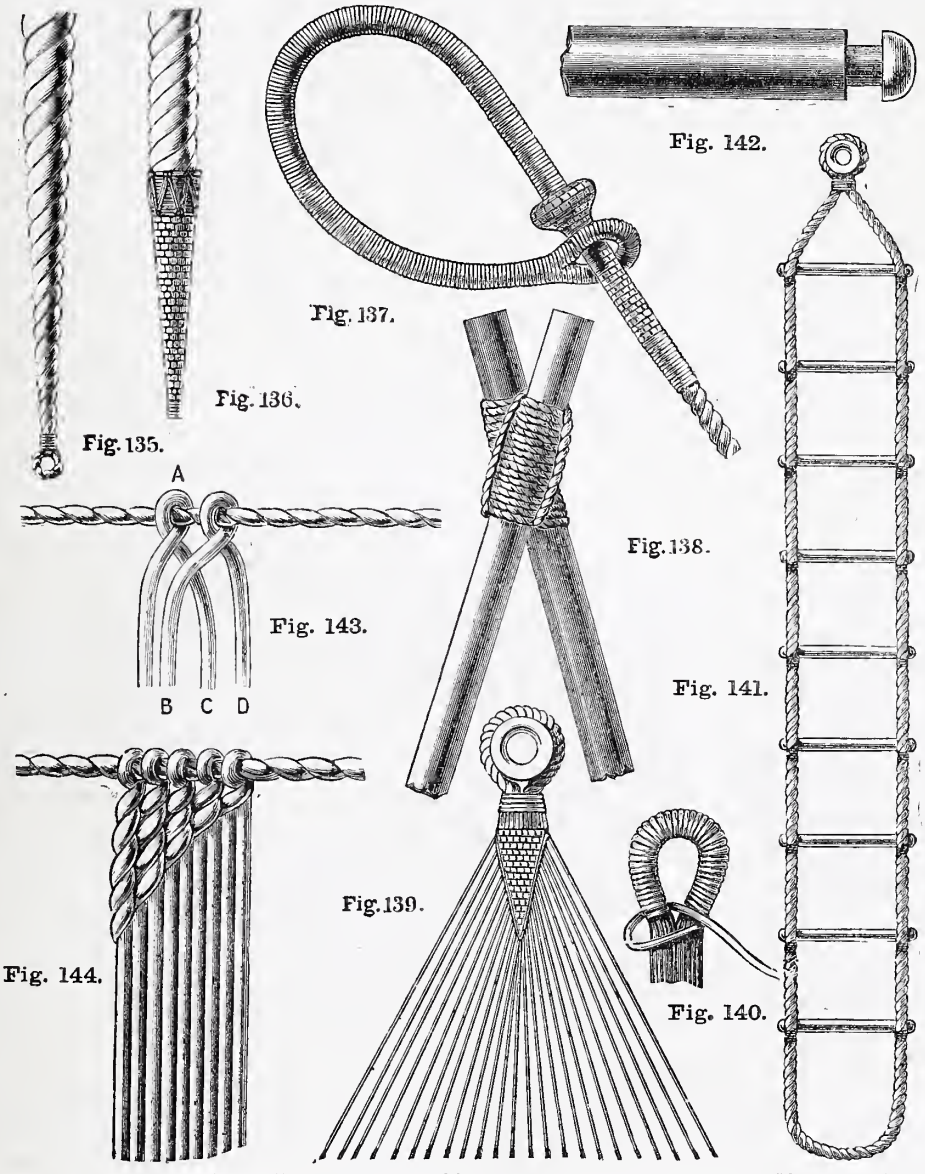

Fig. 135. Fig. 136. Fig. 137. Fig. 138. Fig. 139. Fig. 140. Fig. 141. Fig. 142. Fig. 143. Fig. 144.

**Figs. 135, 136.—Pointing a Rope. Fig. 137.—Mainstay. Fig. 138.—Shear-Legs. Fig. 139.—Hammock Clews. Fig. 140.—Alternative Loop for Hammock Clews. Fig. 141.—Stern Ladder. Fig. 142.—Round of Ladder. Figs. 143, 144.—Mat Making.**

Fig. 137 is part of a *Mainstay*. An eye is first made in the end, and a mouse the shape of a pear raised on the rope with spunyarn. Each turn of the yarn is hove well taut with a large serving mallet, and beaten close. The eye and the rope as far as the mouse are wormed, parcelled, and served over; the mouse and the part below it, which is called the tail, is parcelled with worn canvas, well tarred, and pointed over or grafted with small stuff. The mouse must be covered with nettles, and their number diminished as they are worked into the smaller parts. Below the pointing it is again served over.

Fig. 138 shows the way *Shear-legs* are fastened together. They are first laid side by side, and a lashing of rope put round them. The ends of the lashing are carried one up and the other down to form a cross-lashing, and are knotted in the middle. This is called a Portuguese knot. When the legs are separated, the knot becomes very secure.

The *Clews*, or small cords of a hammock by which it is slung, are usually about the size of fishing-line, but the dimensions of the cords vary according to the number of clews the hammock contains. As in other cases that I have mentioned, the pieces of cord, when cut to their proper length (about 3 ft.), are called nettles. Lay them all together with the ends even. Take hold of them and give them a twist or two in the middle, and put a thimble in the bight and a stop under the thimble. Now divide the nettles into two equal parts, holding the eye in the left hand upside down. Take one of the nettles from the outside on the right,

and lay it across the space between the nettles; do the same with a nettle from the outside on the left; haul upon these till they lie snug down in the divisions between the nettles. Now change the position of the nettles by taking one from the right and laying it over on the left, at the same time taking one from the left and placing it over to the right; repeat this alternately until all the nettles have changed places. Pull them well down, so as to make a clear division between them. Then take two nettles, one from either end of the work, and, crossing them, lay them down in the parting as before. Change the other nettles from side to side, as before, and continue working this way until all the nettles are used up. The last pair of nettles in the middle are knotted. Another pair of nettles being used up every time the nettles are crossed over, the worked part becomes taper, as shown in Fig. 139. The ends of the nettles should be whipped to prevent their unlaying.

A *Hammock*, as I daresay my readers know, is usually made of canvas, and is about 6 ft. long by 3 ft. wide. The ends are turned over and hemmed down, and a row of eyelets, in number equal to the number of the clews, are punched along it at equal distances. The nettles are rove through these, and secured with an overhand knot or two half hitches. When neither thimbles nor eyelets are at hand, an eye may be formed at the end of the clews by serving over the middle of the bundle of nettles with some of the nettle stuff, and then bending it into an eye. The easiest way to do this is to put two half hitches over a hook or anything that is convenient, and, standing at the full length of the serving stuff, gradually wind it on to the bundle of nettles by turning them round and round. The first end is secured by being stowed away among the nettles and served over. The last end of the serving stuff is brought round and through the eye, then round the front of the right part of the eye, round through the eye, and round the left side as at first. This must be repeated thrice, hauling well taut as you go. The end is then brought down, passed through the centre of the nettles, up through the eye, and round the lashing just made, where it is hitched; this must be repeated, and the eye will be secure. In the place of eyelets a hole may be made in the canvas with a pricker, and a small grommet inserted; this must be worked over in button-hole stitch with sailmakers' sewing twine. Of course, the first is the neater method, though the second is quite as strong. Two clews are required for a hammock, one at each end, and it is slung by two ropes spliced into the eyes of the clews.

Fig. 141 shows a *Stern Ladder*. This is made of four-strand rope; the rounds are turned out of oak in the form shown in Fig. 142. The groove at the ends is for the reception of the strands of the rope. The rounds are rather more than 1 in. in diameter, and are placed 11 in. apart. The strands are opened with a marlinespike and the rounds inserted between them, two on each side; a seizing is put on below each round; a round thimble is put into the upper bight, and an eye seizing is clapped on below it. The lower ends are generally spliced together, or a thimble may be spliced in, as at the upper end, if it is intended to make the lower end fast.

*Mats* are used on board ship to prevent chafing. In making wrought mats a piece of small cord is stretched tight horizontally at about the height of a man, and fastened at each end. Across this, hanging by their middles, nettles are placed. These are often made of "foxes"—that is, three or more rope-yarns twisted together by hand, and each rubbed down with tarred canvas or a handful of rope-yarn. Beginning with the nettle nearest the left hand, it is crossed as A (Fig. 143). Another nettle is then brought up close to the first, and crossed in the same way. The end B is then passed over the strand C, and pushed to the back; another nettle is then brought forward, crossed as before, and one part of it put over the part D, and pressed back. The work is continued this way, working diagonally until a sufficient width is obtained (Fig. 144); then, as no more nettles are added, and the outside nettle on the right is brought over from time to time, a selvage is formed as on the left side. Care must be taken to twist each of the nettles together at the bottom, so that they may retain their twist until the next in succession is brought down to interweave with them. There is a little difficulty at starting, but afterwards everything goes on easily. Each nettle from the right passes over the next one to it on the left, and is pushed back, the one that has been passed over being taken up first over the next and pushed back as before. Each twist should be pressed tight as it is made. When the mat is deep enough, a selvage is made by straining another piece of cord along the bottom, securing both ends. As each nettle comes down it is half hitched to this, and the next nettle is laid up at the back of it, and so on alternately. Mats are frequently thrummed, which is done by raising the nettles that lie on the top of the mat with a marlinespike or pricker after it is finished, and putting short pieces of the nettle stuff underneath. The thrums are then cut off to the same length, and opened out. Of course, wrought mats may be made of any material and used for a variety of purposes. They make most excellent door-mats, and are of everlasting wear. For this purpose they should not be made of tarred stuff. Very pretty mats may be constructed of twine for the foundation and various coloured pieces of worsted for the thrums.

There is another kind of mat used aboard ship called a sword mat. It is made in the same manner that weaving is done, only no loom is used. Two small cords, or, better still, two small rods, are secured horizontally and the nettle stuff wound round them, the coils being laid close together. A piece of wood called a "fiddle," as long as the width of the mat and about 2 in. wide and ⅜ in. thick, has half as many holes bored near the lower edge as these nettles in the mat. Every alternate nettle is secured to this by some twine laced through the holes. Another fiddle is fastened in like manner to the remaining nettles. The work is now ready to be commenced. The first fiddle is raised, and the first set of nettles consequently raised with it. What weavers call a "shed" is thus formed—that is, an opening between the two sets of nettles, along which the weft or filling is passed with the help of a netting-needle. The filling is driven well home with a flat piece of wood, tapered towards the edge, called a "sword." The first set of nettles are now allowed to drop, and the second set drawn up with the other fiddle. The filling is passed again and driven home as before. The work is thus continued until there is no longer room to use the sword, when the filling must be worked home with a pricker. When the mat is long enough, the filling is fastened off, and the mat is complete. These mats may be thrummed in the same manner as the wrought mats.

A softer kind of mat is made on a foundation of canvas or duck, which is very suitable for the stern-sheets of a boat or any other similar purpose. The material is cut to the right size and folded a short distance from the edge. A hole is made near the selvage with a pricker and a thrum inserted; another hole is then made a short distance from the first and another thrum put in, and so on until the row is completed. Row after row is thus worked until the mat is finished. Of course the holes, and consequently the thrums, go through both parts of the material. When the canvas is pulled straight after each row is finished, the thrums are held securely without any other fastening. When a pattern is to be worked on the mat, the design must first be drawn on the material in pencil and the canvas folded accordingly. It must be remembered that every fold produces two rows of thrums. White duck thrummed with pieces of cotton rope makes very nice, clean-looking mats for boat use, and as they wash beautifully, they can always be kept in good order. These mats, with a stout canvas or sacking foundation, thrummed with pieces of untarred hemp rope, serve very well for door-mats, though, of course, they will not last as long as wrought mats. Very ornamental mats are made somewhat after the same manner as those just described. Any suitable material, of any colour, can be used for the foundation, on which the pattern must be drawn. The mat is folded along the line intended to be worked, and a common pencil laid along the ridge of the fold. The worsted or other material used is threaded in a large needle, and worked over and over the pencil, thus forming, when the pencil is withdrawn, a series of loops on the foundation. Any pattern can thus be worked, provided always that it consists of straight lines. It might be possible, I think, to form curved lines by working the loops over the first finger of the left hand, moving the finger after each loop, but I have no experience of this. My lady readers will find mat making on this plan a very agreeable and useful employment, as really beautiful mats can be made by this method. I saw one a short time ago, made by a rigger's wife, which would not have been out of place in any drawing-room.

I have endeavoured with pen and pencil to give as clear an account as possible of the various knots and methods of working cordage in general use among seamen, and I hope my readers will soon master the subject. They will find it well worth their while to do so, as there are such a great variety of circumstances where a knowledge of knotting, splicing, and working cordage comes in usefully.

I have not touched on the subject of heraldic knots, partly because I considered it lay somewhat out of the line of my present purpose.

## HARD STOPPING OR BEAUMONTAGE: ITS USE IN FURNITURE WOODS.

BY LIFEBOAT.

INTRODUCTION — PROFESSIONAL *VERSUS* AMATEUR WOODWORKERS—ITS USE TO THE FRENCH POLISHER—ITS ADVANTAGE OVER PUTTY OR BEESWAX AND RESIN—HOW TO MAKE IT — HOW TO USE IT—TREATMENT OF CRACKS, BRUISES, BLISTERS—COLOURED BEESWAX — FINISHING.

*Introduction.*—"It's beaumontage sir," said the boy, when asked by one of his father's customers what he was using. "Yes, but I ordered it to be made of wood, not that

stuff," was the rejoinder. "But this is harder than wood, sir." "Harder than wood, is it? Then tell your father to make me one of all beaumontage."

So the story is told; but whether the boy had been too liberal with its use, using it where wood ought to have done duty, I will not say; but as putty is said to be the carpenter's best friend, we can say that to the French polisher and cabinet maker, especially those that do much in the way of repairs and repolishing—for the one often combines both callings—hard stopping, or beaumontage, *may* be his best friend, if he will use without abusing it, for if carefully selected as regards colour, it is difficult to distinguish it from the wood when polished over.

*Professional* versus *Amateur Woodworkers.*—The professional cabinet-maker, as a skilled workman, should make all his joints fit so closely, and arrange his nails and screws in such a position that their heads will be out of sight, and so leave no holes or defects to need filling up. But even he will find it difficult to select all his wood and ensure himself against any slip or accident so that his work shall present no flaw, shake, or hole that would be none the worse for a composition that shall fill up all defects and render them sightly. True, there are many old stagers who cling closely to beeswax and resin in about equal parts for such a purpose, and they will tell you it suits their purpose very well, though in many cases they only keep two colours in stock—red for mahogany and brown for walnut; at least, the writer so concludes, judging from work that daily passes through his hands.

It is not so much for the professional, who, as I have said, has little need for such a composition as beaumontage, that this article is penned, but for their less fortunate brothers who have to depend largely upon repairs and chance jobs for their livelihood, and for those of our readers, amateur or otherwise, who may have been, or may be, tempted to make some of the many useful or ornamental articles in wood, sketches and particulars of which are constantly appearing in the pages of WORK, and who, perchance, may not have employers willing or at all likely to supply them with perfectly sound material to work with; and there must be some who have found it suit their means best to supply themselves with packing case or other cheap class of wood. In their case they will find it extremely difficult to so select their wood and cut it that no nail or screw-hole, or maybe flaw, shall present itself.

*Its Use to French Polishers.*—The polisher may be called upon to repolish furniture from which little bits of veneer are chipped off, or some bruise, crack, or blister may present itself. The cabinet-maker, with his glue-pot, veneer, and cauls at hand, might let in little bits of wood, or open the blister and run in some hot glue, and apply his cauls, hand-screws, or weights as may be required. Not so the polisher, who may be out of reach of any such help, setting aside the fact that to call in such assistance would take away all his profit, besides hindering him hours, or maybe days, before he could finish his job. Something that will enable him to make level all defects in a short time and enable him to at once proceed with his polishing is found in hard stopping.

*Its Advantages over Putty or Beeswax and Resin.*—If we use putty, in drying it always shrinks, showing plainly in the case of cracks and screw-holes an indentation. If it is used on white wood before staining and polishing its oily nature prevents the stains striking into the wood so deeply as in the parts untouched by it, so causing the work to have a somewhat patchy appearance. If we use beeswax and resin, its chief fault is the want of variety, the colours of which, as I have said, are rather limited, owing to its being kept at hand in most cases in an iron ladle or large spoon, which, by the way, are not the most convenient things for a polisher to carry with him in his kit when going away from home to work.

As hard stopping can be made up in an indefinite number of colours, like so many sticks of sealing-wax—though it is not "harder than wood," yet can, with care, be selected to match any wood we may be working upon, and will not shrink, but retain a level surface, and will, moreover, take polish well—sufficient has, I think, been said to show its superiority over beeswax and resin or putty.

*How to make it.*—The greater the variety of colours the more its usefulness becomes apparent. It gives one a better chance of matching, and ofttimes saves staining such as would be necessary if little bits of veneer are let in.

It can be bought ready-made, at most places where veneers and fancy woods are sold, at about one penny per stick, and is quoted as "stopping-out wax." It is sold by Mr. Palmer, a London shellac and gum merchant, at 1s. 6d. per lb. in various colours; but it is easily made, and one better appreciates anything made by oneself, as knowing its composition lends additional interest.

Having previously planed up two pieces of wood about ⅝ in. thick, 15 or 18 in. long, and 9 in. wide, one of which should be screwed on the bench, take a cupful of any common shellac, put it in a tin or iron pot (half-pound mustard or coffee tin will do), add a teaspoonful powdered resin, and a piece of beeswax the size of half a walnut; then add a teaspoonful of powdered lemon chrome; put it in the oven or on the top of a stove till the whole is melted, stir up with a stick to properly amalgamate, pour a little of the melted composition on the fixed board, then gather it up by means of a scraper or knife, and roll out between the hands, and while still warm roll out into sticks between the two boards by passing the uppermost or loose board to and fro. If the loose board is kept warm by keeping it before the fire when not in use, it gives a better result. Care must be taken not to get the composition *too hot*, as it spoils by boiling. It will require a little practice and, perchance, a few scorched fingers before perfection in the shape of perfectly round sticks is gained.

Having poured out sufficient to make two sticks of this colour, add a little yellow ochre, and make two more; this will give two shades that will do nicely for oak. Then add a little brown umber, warm up again, and roll out two more; those will do for light walnut. Add a little more umber and you are right for dark walnut. Follow on by filling up the tin with shellac, resin, and beeswax as required, adding Venetian red for mahogany, and black for rosewood, and finally finish up with black.

It will be seen that by varving the amount of dry colours any number of shades can be obtained, and it will be found better to take the colours in the order suggested. If the darker colours are taken first it will be found more difficult to obtain the lighter shades, owing to the darker colours clinging to the sides of the tin or pot.

*How to use.*—Any piece of flat iron will do that will retain heat for a few minutes. To give an idea of the most convenient size, I may say that an old worn-out 6 in. flat file in a handle will do admirably, especially if, for an inch or so from the point, the file cuts have been removed by the aid of a grindstone. Suppose it is a crack, nail or screw hole you wish to fill up, select a stick of stopping the required shade, bearing in mind that if it is white wood to be afterwards stained you are at work upon, it will be necessary to select your stopping as near as may be the colour the article is intended to be finished. Then, having your iron black (*not red*) hot, run the stopping into the defective part by holding the iron in the right hand and pressing the stick of stopping against it with the left hand, somewhat similar to the way you have seen the tinker using his copper bit and solder. Do this till you have it well filled up and a little over, then press it well in while the iron is still warm. When cold, clean off level with a sharp chisel, scraper, or knife, and glass-paper.

If it is a shallow bruise it will help the stopping to hold in better if we first make a few holes in the bruised part with a bradawl or chisel. If it is burr walnut, or other fancy figured wood, round holes are best; if straight-grained, such as bay or mahogany, a straight cut from a chisel or knife is preferable.

If instead of dents or cracks the work is blistered, make in it a number of holes—round or straight as required—run some stopping on, and press down with the hot iron. With care this is a far more expeditious plan than opening and putting hot glue underneath and applying weights or pressure. The stopping holds it down like so many pegs or nails.

*Coloured Beeswax.*—It will be found useful if we have at hand beeswax made up of various colours. Slight fissures in the veneers, imperfect joints, or if the stopping has not quite filled up, the defect may, by the aid of these, be made much more presentable.

Heel-ball or cobbler's wax, as one sometimes sees used, cannot be recommended, as it seldom takes polish well. If the coloured beeswax is made up in the form and size of heel-balls, it will be found most convenient, and can be made by oneself by melting and adding the various colours as suggested for stopping, then running it into moulds. The writer has found it a good plan to bore a few 1¼ in. holes through a piece of hard wood, about ½ in. thick; then screw this to another piece and run in the melted wax; when cold, unscrew the top piece—the wax is then easily removed.

*Finishing.*—Having shown how defects in new and old work can be rectified, it is unnecessary here to give particulars as regards French polishing; that has already been done in WORK. Enough for me and our purpose to remind my readers that, if the work is old and been previously polished, it will be found that in making good the defect its necessary cleaning off will leave a bare patch; this should be wiped over with a little linseed oil and "bodied up," allowing a few hours or over-night to elapse before the final bodying up and finishing.

French polishing has already attracted, and doubtless will continue to attract, the attention of many readers of WORK, for whom it seems to possess a marvellous fascination.

## A SMALL POULTRY FARM.

BY G. P.

COVERING FRAMEWORK: OF HOUSES, OF ROOFS, OF RUNS—DOORS: LEDGE DOORS, FRAMED DOORS — WINDOW — INTERNAL FITTINGS: NESTS, ROOSTS, LINING, FLOORS—FINISHING: PAINTING, GRASS PLOT—CONCLUSION.

IN my first paper I described the materials to be used, gave the dimensions of the various parts, and described and illustrated the method of constructing the necessary framework. I now proceed to show how to complete the work.

**Covering Framework.**—Having now got all the framework put together, we may proceed to cover it with the necessary materials. As already stated, Willesden Roofing is to be used for the roofs, and match-boarding for the other parts, although there is no objection to confining ourselves to Willesden Roofing, except that match-boarding will do as well seeing that the house is to be lined inside. One objection to covering with match-boarding is that it is affected by the weather. However, if it is kept well painted, this danger is considerably lessened. For the roof, however, it is an entirely different matter, and I would on no account recommend match-boarding, when Willesden paper is to be had so cheap.

*Of Houses.*—The framework of the houses, then, is to be covered with ½ in. match-boarding. When covering, however, remember to leave spaces for the doors and windows, as shown in Figs. 1 and 8. A small exit-hole must also be left in the match-boarding between the large house and the run, so that the fowls may enter or leave the house at pleasure. This hole should be about a foot square; the edges of the wood should be rounded off; and it should be furnished with a small door, sliding backwards and forwards on two runners, so that at any time communication may be cut off.

*Of Roofs.*—The mode of fixing Willesden paper on roofs is clearly shown in Figs. 4, 5, 6, and 7; there is therefore little need for a detailed description here. When speaking of the rafters, I said they were to be spaced 16 in. from centre to centre; this is so that, when the roofing (which is 19 in. wide) is laid on, the edge of one sheet laid vertically from eaves to ridge, and over the ridge to the eaves on the opposite side, will overlap the edge of the adjoining sheet 3 in. at every joint, and thus make a perfectly water-tight roof. The manufacturers tell us that, "In all cases Willesden Roofing must be fixed with outside wooden battens, 2½ in. by 1 in., and nailed or screwed through batten and roofing to the rafter beneath, in order to provide good holding. Nails or screws should not be less than 2½ in. to 3 in. long." Always follow these instructions (see Fig. 6). These outside battens should be of good wood, free from sap and large knots, and must receive three coats of oil paint before fixing. When cutting the roofing, care should be taken to allow sufficient to turn under the eaves board (Fig. 6), which bend may be easily effected by placing the *ends* in water for fifteen or twenty minutes, but *never* plunge in the whole sheet. As "accidents will happen even in the best regulated households," it is well to know how to repair any accidental damage. All that is required is to fix a piece of 1-ply Willesden paper on each side of the fracture, with a waterproof solution composed of white lead and best gold size. I have no doubt that Waterproof Liquid Glue would suit the purpose quite as well, although I have no experience of it. When the Willesden Roofing is fixed, and the fascia and soffit boards put on, the ridge will have to be made and fitted on (see Fig. 7), after which the small turned pinnacles (see Fig. 1) are fixed on. This completes the roof, and we will now turn our attention to the run, and the fence round the grass plot.

*Of Runs.*—With regard to the run, the framework circumscribing it must first be covered, 2 ft. up, with ¾ in. boards—of course, omitting the space which will afterwards be occupied by the door (see Fig. 1). This done, the remaining portion is covered with 2 in. mesh wire netting,* 2 ft. wide, and the edges of this are covered by nailing over them small laths, 1 in. broad and ¼ in. thick; this prevents the loose ends of the wire from tearing one's clothes, or scratching one's hands, should one happen to come in contact with them. The top is covered with similar wire netting, but first we must have supports on which to fix it. For these we shall require three pieces of wood 8 ft. 4 in. long by 1½ in. broad by ¾ in. thick; these are fixed at equal distances along the top. The top rails are rebated to receive them, as shown in Fig. 9; the ends of the supports are laid into these rebates and nailed down to the top rails. The wire netting is then laid along lengthwise, and fixed with small wire staples.

It is well to have a portion of the run covered at the top, so as to afford shelter for the fowls in rainy weather. The Willesden Roofing may be used for this also. Before fixing the wire round the grass plot, it is well to nail a narrow board at the foot of the posts round the plot. This furnishes a firm hold for the wire netting at the foot, so that there will be no possibility of small chickens escaping under the fence. The board should be 4 in. wide by ¾ in. thick. It should first be well tarred, and then

* Mr. Scott's article on "Wire-work," on page 437, Vol. III., of WORK, should be carefully read.

placed an inch or two into the ground. The netting is then fixed with small staples, and, if the fence is composed of two lengths of netting, one above the other, the edges must be connected with galvanised tying wire—*i.e.*, the top edge of the lower length must be connected with the lower edge of the top length.

**Doors.**—We now come to what will be to many the most difficult part of the construction—viz., the doors. The doors for the hen-house and coops are of the kind known as "ledge doors." Those leading into the grass plot and the run are "framed doors."

*Ledge Doors.*—As already stated, three of these are required: one for the hen-house, and one for each of the two coops. Fig. 10 is an illustration of the hen-house door. No description is needed, it would only waste valuable space. The doors for the coops are similarly constructed, but are 4 ft. long by 1¼ ft. broad.

*Framed Doors.*—The illustration (Fig. 11) shows the elevation of a framed door. Two doors are necessary, but both are the same size. They are for the entrances to the grass plot and the run, and are of this kind because they present a much more satisfactory appearance. Ledge doors would certainly look very out of place in the positions in which I have shown the framed doors in the illustrations; and framed doors would be equally out of place in the positions occupied by ledge doors. The doors consist of three rails, A, B, and C, of which B and C are wider than A; two long stiles, D and F, forming the sides of the door; a panel, G, which is inserted in grooves cut in the stiles and rails for its reception as shown in the Fig. by the dotted lines, H, I, J, K; and, lastly, a piece of wire netting, L, which is nailed on the inside of the stiles and rails. The dimensions of the door and its different parts are marked on the Fig., and it only remains to add that the stiles and rails are 1¼ in. thick, and that the panels are made of sound, straight-grained ½ in. stuff. The rails and stiles are joined by mortise and tenon joints. The doors must now be hung and latches put on; those for the house and run doors should be similar to those shown in Fig. 1, while the other doors are fitted with 3 in. cabin hooks.

**Window.**—A small window is shown in Fig. 1: this is 21 in. long by 15 in. broad, and is made of two pieces, 21 in. long by 1½ in. broad by 1½ in. thick, and two pieces, 15 in. long by 2 in. broad by 1½ in. thick, mortised together. This frame is divided into four smaller frames by two cross-pieces, 15 in. by 1 in. by 1½ in., and 21 in. by 1 in. by 1½ in., joined at right angles to each other, and mortised and tenoned to the frame, as shown in the Fig. The window is then glazed with 15 oz. glass and hinged to the top horizontal rail with two 1½ in. butt hinges, so that the sash may be opened upwards and inwards. This concludes the outside work for the present, so we may proceed to fit up the inside.

**Internal Fittings**: *Nests.*—With regard to nests, they may be of any form, but are best on the ground. A long box may be employed, divided by partitions into separate compartments; or separate boxes may be used, which is preferable, as they are more easily cleaned. These separate boxes are illustrated in Fig. 12; they are open at the bottom, and also in front, with the exception of a strip, 3 in. high, to contain the straw. A piece of wire netting should be nailed over the bottom of the box to prevent rats from burrowing their way in; and the nests may then be placed in a row at the end of the house at which the window is placed, so that the fowls may be shaded from the light. The nests for the coops may be arranged any way, so that no one can see into them, with the one proviso that they be actually *upon the ground*. Chicks thus obtained always show more constitution than those hatched on a wooden bottom at a higher level. Let one of the boxes above described be placed in the back corner of the coop, touching the side, the front being turned to the back wall, and about 9 in. from it. The hen will be in the strictest privacy, and will be both perfectly sheltered and kept cool. Inside the nest put a layer of *damp* earth, or, in frosty weather, *ashes*. Make a hollow in the middle of this, and line the nest with straw cut into short lengths, and a few feathers in winter, sprinkling with a handful of flower of sulphur in summer.

*Roosts.*—Two perches will be required; these should be fixed not more than 18 in. from the ground, should be 1 ft. apart, and 4 in. in diameter. A rough pole with the bark on answers best; the claws cling to it nicely, and bark is much softer than planed wood.

*Lining.*—It is really necessary to line the interior with some sort of material. For this I recommend Willesden 1-ply paper, 56 in. wide, at 6d. per yard run for brown. Thus we get about 13¾ square feet for 6d., which is surely as cheap as anyone could desire for the excellent material obtained. The paper should be laid vertically, with an overlap at every joint of not less than 3 in., and be firmly tacked along the edge with galvanised tacks, 1 in. long. These joints must all come over the uprights.

*Floors.*—The floors of the houses and run should be covered with at least 3 in. of gravel, which should be renewed every year. This is essential, for in a short time the poultry will have cleared off all the *sharp small stones* which are so necessary for assisting them to digest their food.

**Finishing**: *Painting.*—The whole structure

LIST OF MATERIALS REQUIRED.

| | | | | | | 6 17 7 |

should now receive three coats of paint. The houses, runs, etc., should be painted "stone" colour, and the roofs, "slate" colour. "Ah!" says some more than usually attentive reader, "you told us the Willesden paper was waterproof; and if that be so, why is it necessary to paint it, for paint is usually applied to articles to protect them from the ill-effects of moisture?" Yes, you are right; but does not Longfellow remind us to

> "Trust no future, howe'er pleasant,
> Let the dead past bury its dead!
> Act—act in the living present!
> Heart within and God o'erhead."

Therefore, let us "trust no future," but "make assurance doubly sure" by painting our roofs, even although made of "Willesden 4-ply paper."

*Grass Plot.*—The best time for sowing grass is in the spring, at the end of March. Dig the ground even, rake it perfectly level, and then sow with a mixture of grass and clover, at least 2 oz. of the mixture to the square yard, passing a roller over afterwards; or, what is the same thing, treading well, and afterwards beating with the back of a spade. When your grass becomes well established it should be frequently cut and rolled; cutting alone will not secure a good bottom without the compression which the roller tends to give.

*Conclusion.*—In conclusion, I may say that late autumn is the time for building your houses and runs. Secure good vigorous stock. Do not keep too many—twelve or fifteen are plenty for the house described. Do not feed wholly on corn or corn meal. Avoid damp soil. In winter look out for cold draughts of air, such as come from broken panes of glass. Remove the droppings from under the roosts at least three times per week. The hens must have a place to dust themselves, if you do not want to feed a lot of vermin. Dry sand, sifted ashes, with a little sulphur, will be excellent. There is one more essential for winter eggs—hens of suitable age. I prefer chicks hatched the last of April or beginning of May. After your chicks are hatched feed them liberally. But, you will say, is all this necessary? Yes, it is for the best results in this climate. And if you do not want to do the work, don't blame your hens because they don't lay. Answers to queries will be attended to in "Shop."

Thus the principal materials for our poultry-yard cost £6 17s. 7d. To this a few items must be added, such as gravel, nails, paint, etc., but these would not bring the cost up to more than £10. Then the labour item enters in and makes a big difference, for if a workman were employed to make a house, etc., according to the above plans, he would never think of charging less than £50. This amount the real student of WORK will save himself.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 108.—An Electric Night Light.

The long, dark, winter nights are still with us, and early risers have yet to use an additional number of matches in consulting their watches during the small hours of the dark mornings. To such, the latest electrical novelty brought out by the Electric Stores Co., London, E.C., will be hailed by our readers as a great boon. This novelty consists of a mahogany box, nicely polished, and fitted with four cells of the E.S. dry battery connected to a 4-volt incandescent lamp fixed to the front of the box over a hook and velvet pad, on which is to be hung the watch of the owner. A flexible cable of insulated wire, terminating in a pear-shaped pressel, is coiled on a brass cleat on the side of the box. The box may be placed on the dressing-table, a watch hung against the velvet pad, the cable uncoiled, and the pear pressel placed under the pillow. When the owner of this novelty wishes to see the time, he has only to place his hand under his pillow and push in the stud of the pressel, when sufficient light is given by the lamp to see the time on the watch and light up the room enough to see all the objects in it distinctly. By fixing a small switch on the box and connecting this to the lamp, it may also be used to light the room whilst dressing or undressing. It is not advisable to use the lamp for more than ten minutes at a time, or the battery will soon run down; but with moderate use one battery should last during the winter months. As I have only had this novelty in use for a few weeks, I cannot vouch for its durability; but, as the material and workmanship are good, it ought to last for many years with an occasional renewal of battery cells. These are perfectly dry and safe to use; they give off no fumes nor offensive odours. The price of the set complete is 32s. 6d.

### 109.—Angel's Collar and Saddle Linings.

Though the horse is the best slave man has in the animal world, much of man's industry is devoted to waiting upon the horse, which shows that reciprocity exists to a large extent. For seat, the back; for draught, the shoulders of the animals have to be guarded from harm. How best done has occupied the thought, skill, and labour of humane man of all ages since the horse was subdued to saddle and harness. The main part of the horse to be guarded from injury is the shoulder, where the collar bears. Collars are made so variously now that the saddler must be a mechanical craftsman to be equal to making and repairing some of the collars horses wear in England and on the Continent. But, after all, the wear, like the wear of the sole of a boot, must be repaired from time to time, if the bearing is yielding stuffing or straw, flock, or other such matters. Dray and 'bus horses are subjected to great pressure on the skin of the shoulder and underlying muscles and blood-vessels. We cannot feel what the horse feels, but can imagine the persistent concussion of the collar on the shoulder of a horse that has three or four tons to haul at a trot often, must be painful if the bearing surface of the collar becomes hard and badly fitting; for after a certain point of fitness has been obtained by wear, then the collar becomes gradually ill-fitting, pressing on parts of the neck, throat, and withers, which should not be pressed upon severely, and the unyielding, compacted stuffing causes the collar to be as hard as a board. Galls and sores result sometimes; then, when the horse cannot earn money for his master, relieving the collar is thought of and done, and the horse is rested for the shoulders to get right again. This was noticed by Mr. Angel, a gentleman who has to do with a firm using many horses for heavy draught; and the frequency of the collars going to the saddlers' to be re-lined at 3s. 6d. each time, sometimes with unsatisfactory results, suggested to his inventive faculties that a simpler plan would be to have suitable linings ready made up and formed with a lacing-in arrangement to the "wale" and "face" of the collar. Being practical, he soon had the lining made of stout flannel, known as collar-serge, and two thicknesses sewn together, and a lace run in in loop-stitch form, round the edge. This lace is run through the metal eyes sewn on all round the collar-face and "wale," so that it can be laced in quickly and as quickly removed. This thin lining is stuffed with granulated cork, which has an agreeable yielding spring to the pressure of the horse's shoulders in drawing loads, and its well-known non-absorbent qualities prevent saturation by perspiration, so that sweating under the collar is lessened. As their prime cost is less than collar lining, and carters can take them out to dry and put them in easily again, it is obvious that there is economy as well as philo-animo feeling to recommend their adoption. They are patented, and have had about two years' successful trial with the leading brewers and carriers in London.

### 110.—Philips' Patent Revolving Orrery.

The Patent Revolving Orrery, which was invented and patented by Mr. J. G. Parvin, and is published by Messrs. George Philips & Son, has been sent us. It is a cleverly constructed and inexpensive appliance for finding the position of the various planets for every hour in the year, for indicating the position of a planet, the moon, or a fixed star, and for telling at what hour they will rise, south, and set. It will also indicate the phases of the moon, and show when eclipses will take place. It consists of two parts, which may be roughly described as two cards, one square and fixed, the other a movable circular disc. The square card is about 8¾ in. square and 12¼ in., or very nearly so, in diagonal measurement. The round card is 10¼ in. in diameter, and is placed concentrically on the square card and above it, being pinned thereto by a wooden knob with a spill that passes through both cards and is then fastened down, the circular card revolving on the spill as about an axis. The edge of the circular disc is marked with concentric circles nearly ⅛ in. wide. Of these, the first and outermost is divided into degrees, the second into hours, the third shows the signs of the zodiac, the fourth the seasons, the fifth the names of the months, and the sixth the divisions corresponding to the days of the months numbered consecutively, or, rather, in alternation, as the space at command does not admit of more than this. Above the circular disc is placed another card, also square, which is fastened to the square card below the disc at the four corners, the edge being cut in such a manner between the corners that the graduation and lettering on the bands at the edge of the disc are visible. The edge thus formed on the topmost card, which is covered with paper in imitation of grained leather, is divided into twenty-four spaces corresponding to the twenty-fours of day and night, and, moreover, shows relatively morning, noon, evening, and midnight at intervals of six hours. In the inner portion of the circular disc the zodiacal belt, comprising the twelve signs of the zodiac, is drawn. Within this broad belt the motions of all the planets are performed, and on it are shown the positions of the stars that form each sign. Screwed concentrically to the central knob or button already spoken of are two brass hands, one to represent the position of the sun, and the other that of any planet. These hands are slotted and graduated in degrees along the edge, and in the slot of each is a pointer. It should be said that the large oval opening in the uppermost square card, through which the zodiacal belt appears, represents the actual horizon. With this appliance, on the back of the square card, is given, first of all, an explanation of all the astronomical terms that apply to this instrument, and this is followed by full and clear directions for using the orrery. These, however, take up too much space to be inserted here, and they would not be clear and intelligible if they were given, seeing that it is highly desirable to have the instrument before you when attempting to follow them. For this reason I have confined myself to a description of the instrument itself, in the hope that this, coupled with the mention of the various results that may be arrived at by its aid, will induce many to get the appliance and try for themselves what they can do with it. It seems likely to be of use, not only for children in private families, but in schools also, and especially in those where apparatus of a more costly character, in the form of a celestial globe, cannot be afforded.

THE EDITOR.

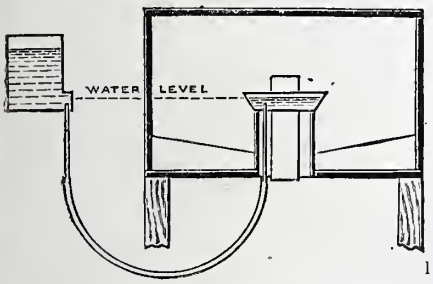
## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Incubator.**—LEGHORN writes:—"Since writing my Incubator article I have been experimenting with a view of providing some easier method of keeping the water in evaporating tray quite constant. Whilst visiting the late Dairy Show I was impressed with an idea which has since borne fruit. My improved plan consists of the adaptation of the principle of the ordinary poultry fountain, of which I subjoin a rough sketch, but which, I think, will



Evaporating Arrangement and Fountain.

make matters clear. The figure on the left is an air-tight zinc vessel, of rectangular form preferably, with a semi-circular piece cut out of the front at the bottom, and round this is soldered a semi-circular cup, into the bottom of which is soldered 2 or 3 inches of small brass tubing. This is to be connected with the 'overflow' pipe of evaporating tray with rubber tubing. The fountain part of the business will, I take for granted, be understood by all, so that by the laws of gravitation of liquids it will be seen that the height of water in the evaporating tray will be on a line with the water in the cup of the fountain, which should, I think, stand on a shelf away from the incubator, or might be hung by a nail to a wall, a lug being soldered on the back for the purpose. By raising or lowering the fountain we have therefore ready command over the water inside the machine, which can be increased or diminished as required, according to the state of the external atmosphere. The water container is easily filled from a jug without disconnecting, by tilting it, as in filling an ordinary poultry fountain. If made 6 in. high, 4 in. wide, and 3 in. thick, it will hold about a quart; if 2 in. by 4½ in. by 3½ in., about 3 pints; and if 8 in. by 5½ in. by 3½ in., about half a gallon. If not clear to anyone I will endeavour to give a more lucid description."

**Incubator.**—H. E., otherwise LEGHORN, writes:—"Replying to B. A. B. (p. 571, No. 140), I beg to apologise if I have been too impulsive in criticising his suggestion on p. 461, No. 133; at the same time I must repeat that his suggestion is utterly useless for the purpose recommended. WORK is nothing if not practical, and I deem it the duty of every reader to correct any representation he *knows* to be wrong. No, Mr. Editor, I have not tried B. A. B.'s plan, as it is quite needless to test foregone conclusions. It is freely conceded that 'mercury is used in several instruments' where its expansion is 'the feature of the invention'—the thermometer, for example; but surely B. A. B. does not contemplate regulating an incubator on this principle? If so, using a tube of proportional size to that figured on p. 461, he will require a bulb considerably larger than the incubator he is about to regulate. I certainly do not know what query evolved that reply; but the 'suggestion' is quite as remarkable as such as it would have been as an 'invention.' My remarks were not, and are not, written in a hostile spirit, but merely to save others from falling into the same pitfalls as I myself have done in past days when I had no beacon-light ahead. I note B. A. B.'s covert allusion to my criticism of Mr. Walker's incubator, but this was surely unnecessary, as neither he nor anyone else can, I think, justly find fault with that criticism. Before this is in print *my* article will probably be published, and if B. A. B. or any competent reader can improve on it, I hope they will do so, as much for my own benefit as for that of any other interested subscriber. Further, replying to L. G. W. (p. 573, No. 140), permit me to add that my regulator will suit Hearson's machine as well as any other, but as L. G. W. has one of their machines, he will find no difficulty in getting one of their patent regulators, if he can return the old one, but not, I believe, otherwise."

**Tempering Axes.**—J. C. K. (*London, N.W.*) writes:—"You must not quench the axe in salt and water as directed (see page 573, No. 140); it would spoil the eye, making it too brittle. It should not be 'low red,' but 'cherry red' heat. 'Then let down;' and to 'let down' should be explained, and how it is let down: here is the *main art* of tempering axes, or spoiling them by doing it wrongly. 'If you find the temper is soft,' etc., shows J. is only a poor describer of perhaps what he knows."—["My correspondent, J. C. K., says: 'You must not quench the axe in salt and water as directed; it would spoil the eye, making it too brittle.' Nevertheless, I repeat that salt and water is a very good and very common mixture, not only for axes, but for other tools. And besides salt, I might have named with equal truth such medicaments as saltpetre, sal-ammoniac, prussiate of potash, and other salts, all of which have a decidedly intensifying effect, and are therefore employed by many workmen who know full well how to do any job of tempering. My correspondent says, 'it' (the salt) 'would spoil the eye, making it too brittle.' Now, if J. C. K. knew much about the matter, he should be aware that the eye of a manufactured axe is not made of steel, but of iron, which cannot possibly be tempered, but that steel is only used for the cutting edge and for the poll. But supposing that the axe is made entirely of steel, as in a home-forged job, even then the eye is never tempered. It is not tempered any more than the shank of a cold chisel, or of a drill, or the tang of a file is tempered. It is the cutting edge only, and the steel for from half inch to an inch back from the edge that is let down and quenched, and so tempered. The veriest tyro knows something about these things, and I thought also that I had made these elementary matters clear in my paper on 'Hardening and Tempering,' on p. 546 of the present volume. Again, my correspondent says: 'It should not be "low red," but "cherry red" heat.' I ask, Why one more than the other? So long as the steel is not overheated, either will do, and if it makes no difference which, why say one is wrong and the other right, in a captious fashion? You shall take half-a-dozen smiths, and each one will quench at a different tint, and each, if asked, will name similar tints by different qualifying terms. Besides, a cherry red on a dull day will be a low red on a bright day, and how will you draw a line, unless you use degrees Fahr.? Further, if J. C. K. had done much work in steel, he would have learned ere now that almost every separate brand of steel requires to be worked at a different temperature, and also requires different manipulation, hammering, etc. Again, my correspondent complains that I do not explain how the tool is 'let down.' No, I did not; but I certainly thought that a correspondent who asks for information about tempering a particular tool has also the very elementary knowledge involved in the understanding of the term 'to let down.' Set information on elementary matters is given in articles, as in that of mine, for example, on p. 546; when questions are asked, the reply is confined rigidly to the scope of the question. Lastly, my critic finds fault because I say: 'If you find the temper is soft,' etc. Yes; and I repeat it most emphatically: if the temper is soft the tool must be re-tempered at a higher grade of heat. Unless you use a lead bath, which is done by wholesale manufacturers, and steel of a uniform grade, tempering tools is always a tentative operation, so that a tool may have to be re-tempered three or four times over, not merely where amateur work is concerned, but by skilled tool smiths. My correspondent ends: 'J. is only a poor describer of perhaps what he knows.' Well, I didn't ask J. C. K. for his opinion, and if I please the readers of WORK generally, that is all I care for. Still, it is well that he should know once for all that the staff of WORK is not composed of hack writers by profession, whose literary work is a mere digest of their *reading*. J. has earned his living as an engineer for thirty years past, and earns it thus still, and knows how to work, even if he is a 'poor describer' of what he knows. And he will always be glad to learn a thing or two from J. C. K., or any other correspondent, always provided the element of personal criticism is left out, for this is not suitable to WORK."—J.

### II.—Questions Answered by Editor and Staff.

**Piano.**—A. P. M. (*Notting Hill*).—I would advise you to purchase the Index to Vol. I. of WORK, and also the numbers relating to piano making. You will see the address of an ironmonger, where you will be able to obtain an iron frame to suit your requirements. You will also find the address of action makers; if you write or call on these firms, you will be able to get prices.—T. E.

**Piano Making and Hand-screws.**—J. W. H. (*New Lenton*).—We are always willing to assist our readers, and pleased to know that you have received help from the pages of WORK. I should write to G. Buck, tool-maker, Tottenham Court Road; or Berry, Old Street, St. Luke's, London, for your hand-screws, or try Melbuish, Hobday, and others who advertise in WORK. For making wrest planks, iron cramps are generally used in factories, but if your woodwork is well planed and true there is no reason why hand-screws should not give all the pressure you require. I should advise you to order 18 in. screws for large work, such as ends, cheeks, tops and wrest plank, but a few 12 in. screws would be useful for general work. The price is usually one penny per inch, measuring the length of the drops, not the screws, so that 18 in. hand-screws would be 1s. 6d. each. You ought to get them in Nottingham.—T. E.

**Fork Crown.**—J. B. (*Dundee*).—The fork in the rough for narrow or broad tires can be bought of Brown Bros., Great Eastern Street, London; St. George's Cycle Co., Upper Street, Islington, London: Home Company, Bridgeton, Glasgow, and most cycle dealers. It does not require to be hardened after being brazed to steering tube.—A. S. P.

**Electric Scarf Pin.**—H. B. R. (*Leeds*).—Your friend was right. An electric scarf pin was described in "Shop," p. 520, Vol. II., in No. 84, and a battery for the same was described and illustrated at p. 792, Vol. II., or in No. 101. Both pins and batteries are now supplied by Messrs. Cathcart, Peto, & Radford, whose address has been given frequently in WORK.—G. E. B.

**Whitening Piano Keys.**—PIANO.—As you have scraped and polished your keys, and you say that yellow streaks still remain, it is probable that they are stained entirely through the ivory. You might try to bleach them by allowing a little spirits of turpentine to remain on them for a short time, keeping them exposed to the light. If this does not answer, I am afraid there is no other alternative than by having them replaced by ivory or celluloid, which would cost less than ivory.—T. E.

**Dulling a Blackboard.**—ART T.—If you will consult the indexes to Vols. I. and II. of WORK, you will find many references as to how to treat blackboards.

**Aquafortis.**—T. B. (*Sheffield*).—There is no method of making aquafortis less fluid and of a gummy consistence. By boiling, it would all boil away without getting thicker: but by freezing to −67° Fahr. it becomes a buttery mass. Of course it would have to be kept frozen; for, as the temperature rose, so would it become more and more liquid until it again reached its normal condition. Had you mentioned for what purpose you required it, I might have suggested some method of overcoming your difficulties. For instance, phosphoric acid is added to very fine sand until the sand will not absorb any more without becoming quite wet. In this state the acid can be conveyed, and is often sent abroad in barrels. For many purposes the presence of the sand is of no moment, and thus the acid is carried in a solid instead of liquid form; whereas, if the presence of the sand be objectionable, the acid can be washed out with water.—F. B. C.

**Chemistry.**—B. E. (*Plaistow*).—The best book on the manufacture of sulphuric acid is Dr. Lunge's "Manufacture of Sulphuric Acid and Alkali," Vol. I. "Sulphuric Acid," published by Gurney and Jackson, Paternoster Row, at £2 2s. A new edition has just come out, and contains 374 illustrations, drawn to scale. This is the standard work on the subject, and will contain all you wish to know. It might, however, be sufficient for your purpose to consult Dr. Ure's "Dictionary" of Chemistry as applied to the Arts and Manufactures," which you could see at the London Guildhall Library. The best book of tests for metals and acids is Clowe's "Practical Chemistry," published by J. and A. Churchill at 7s. 6d. Thorpe and Muir's "Qualitative Chemical Analysis," published by Longmans, Green, & Co., at 3s. 6d., is also a good book, and has the advantage of being cheaper, although I prefer Clowe's.—F. B. C.

**Mathematical Instruments.**—G. B. H. (*Leeds*).—I bought a small set of instruments for a guinea in Holborn some six years ago, and they have proved very satisfactory. But there is no need to send to London, for any good mathematical instrument-maker (and there must be several in Leeds) will sell you satisfactory instruments singly. These instruments depend principally upon the material of which they are made, and if you require good tools you must be prepared to pay for them. Do not get any that are all brass, those with steel points wear far better.—F. B. C.

**Chromic Acid Battery.**—AMATEUR ELECTRICIAN.—The glass jar form of chromic acid cell as shown in your sketch is constructed as follows:—Procure a glass jar similar to those in use by confectioners. Get a cover of mahogany turned to fit the jar, and collar of brass fixed to this cover, fitting the jar as shown in your sketch. Have the cover smooth and nicely polished. Now get three carbon plates, reaching from the cover to within ¾ in. of the bottom of the jar, and cast a lead head on each, enclosing a brass screw pin for connections. These pins will come up through the cover, and be secured by small brass nuts to a strip of brass connecting all three together. On one of these strips must be mounted a binding screw, to form the positive terminal of the cell. Next, get two zinc plates half the length of the carbon plates and ¼ in. in thickness. In one end of each drill and tap a socket for the screwed end of a ¾ in. brass rod two-thirds the length of the carbon plates, and screw these rods into the zincs. These rods should terminate in brass knobs, and must slide tightly in two pieces of brass tube soldered to two brass strips secured to the cover; the brass strips must be connected together, and fitted with a binding screw to form the negative terminal of the cell. It will be readily understood that the brass strips to which the carbons are connected must not touch those coming from the

zinc plates. If the rods holding the zincs are made to slide stiffly in the brass tubes, the plates will be held up when drawn out of the solution, and a good conducting connection will be formed between the terminal and the plates. There should be an inch of space between the carbon plates; this will give nearly half an inch between the zinc and carbon surfaces. A chromic acid cell thus constructed will have a low internal resistance, and give a large volume of current through a circuit of low resistance. Its E.M.F. will be two volts—no higher than a smaller cell—and therefore will not be more powerful than a small cell in a circuit of high resistance, such as that of a small electro-motor. Two cells of pint size will suit your purpose better, as you only want to work the motor for a few minutes at a time.—G. E. B.

**Induction Coil.**—R. M. (*Chingford*).—Replying to your questions in the order put by you:—(1) If you put four layers of wire on the core for a primary instead of two layers, you will increase the resistance of the primary circuit and the inductive influence of the coils on each other, but you will also increase the magnetic reluctance of the core and the back current in the primary. The probable result will be a less efficiency in the coil, unless a good condenser is employed, and also a strong battery. (2) If you use No. 40 wire instead of No. 36, a thinner spark will be obtained from the secondary; and if the same weight of wire is employed in both cases, you should get a longer spark from, say, a pound of No. 40 than you would from a pound of No. 36. (3) The divisions made in induction coils are intended to divide the total electrical stress of the current in the secondary circuit. By splitting the secondary circuit into sections, and separating these from each other by insulating divisions, the danger of internal sparking is reduced to a minimum. All coils to give over a ¾ in. spark should be thus divided. (4) For a core 6 in. × ¾ in., use ¼ in. ebonite for the ends. Use two layers of No. 18 silk-covered wire for the primary. With 12 oz. No. 40, and a condenser of 60 sheets 4 in. × 4 in., you should get a ¾ in. spark when worked with current from three cells.—G. E. B.

**Hot-Air Engine for Dynamo.**—W. (*Bradford*).—As I have not had any practical experience with the Robinson hot-air engine mentioned on page 570, Vol. III., nor know any person who has worked one, I cannot pronounce on its merits as a motor. If it will do all that its inventor and its makers claim for it, there should be no difficulty experienced in its use as a motor for a small dynamo.—G. E. B.

**Driving Cotton-Spinning Spindles by Electricity.**—P. W. (*Stalybridge*).—There need be no difficulty whatever experienced in applying electricity as a motive power to the driving of cotton-spinning machinery. But if you already have sufficient power, and this has been applied to the machines, why desire a change? If you have to convert steam-power into electricity, and re-convert this into motive power for the spinning engines, the extra cost will be something considerable for plant alone, and you will only get 80 per cent. of the steam-engine's power in the spinning machinery. If, however, you wish to build a new mill in the vicinity of water-power, and wish to bring this power to your mill by other means than gearing, rods, or chains, then it might be advisable to have a powerful dynamo, driven by the water motor, and transmit the electric power to the mill through wire cables, where it can be used in driving electro-motors attached to the machinery. In any case, there need be no alteration of the spindles or machinery, the same wheels and the same bands being used, and any required speed can be obtained from an electro-motor.—G. E. B.

**Oak Panels in Cabinet.**—T. A. (*Little Bolton*).—I fear "Shop" space is too valuable at present to give a design suitable for utilising your oak panels. It might be too elaborate for the use of other readers. But perhaps you could convert the cabinet in No. 141, Vol. III., in such a way as to accommodate your panels; then you will find plenty of designs which are applicable for the carving—not in the style of the periods you mention, perhaps, but still very good. The sideboard in Vol. I. (see Index, price 1d.) might offer many attractions for you. Back numbers contain several designs which could be put to serviceable use.—J. S.

**Writing-Desk.**—AMATEUR (*Paddington*).—"The way to make a writing-desk . . . . about the average size," is rather a vague question. I presume you mean a small portable article; but I would like to know if I am right, or whether you need an office desk, or *what*. About the time you see this, drawings will probably appear in "Shop" relative to a small box desk with hinged flap—similar to an office article.—J. S.

**Model Electric Lights.**—E. P. (*Waterloo Road, S.E.*).—(1) I congratulate you on your success in making electric lamps. The cement employed in connecting the carbon filament of the Bernstein lamp with its platinum wires is merely finely powdered coal-dust mixed with an ordinary cement. Some makers clip the ends of the carbon filaments in sockets made of flattened wire, and then electro-deposit copper on the joint to make it secure. I had no idea of anyone attempting to manufacture lamps from the instructions given in my articles on "Model Electric Lights," so did not give details of their manufacture therein. (2) Platinum wires must be employed to conduct the electric current through the glass stem of the lamp, because no other metal will expand in the same ratio as glass when both are heated. Platinised copper would expand more rapidly, and thus crack the glass. (3) The voltage of current from a dynamo may be increased by winding a finer wire on the armature, but such finer wire would not have the capacity of the larger wire, and in consequence, the volume of current in ampères would be reduced, or the insulation of the wire destroyed by internal heating of the machine. If there is room enough on the armature, the number of turns of wire and the voltage may be increased, but then there should be more wire on the fields to balance the wire added to the armature coils. Driving the machine at a higher speed will increase the output of current. If you wish for a greater output, choose a larger machine.—G. E. B.

**Blacksmith's Forge.**—S. S. (*Grantham*).—In my sketch of spark arrester I am assuming that the lower part of the chimney is brick; you say that the top is composed of a C.T. stove-pipe. To fit the arrangement on the top would be rather inconvenient, as you will see. I have shown in Fig. 1 a rough perspective sketch of the hearth and chimney of a blacksmith's forge; a part of the chimney I have shown broken away, in order to give a better idea of the position of the spark arrester, which is shown to a large scale in Fig. 2. Should your stove-pipe (4 in. diameter) start from the fireplace, you must yourself arrange from these sketches some contrivance to suit. Just below the spark arrester the chimney should be round in section, as shown at A; so if your chimney is now square—which most probably is the case if it is brick—you should have it made round, as shown in Fig. 2. Centrally above A must be hung a circular metal deflector, B, two and a half times larger than A, somewhat in the shape of an umbrella with the upper part pushed down, thus forming a hollow in the top and a corresponding projection inside, as shown (Fig. 2). This must be carried by a bolt, C, hung from the centre of a moderately fine-meshed wire gauge screen, D, considerably larger than the diameter of A: say, about three and a half times. This increase in diameter is so that the smoke will have sufficient area to pass through the gauze, as it will be considerably obstructed thereby. This screen should be built into the chimney, which should be enlarged as shown. E is a circular cast-iron water-trough running concentrically round A; there should be an overflow pipe for the water from it, or the trough, as it becomes filled with ashes, will overflow; an inlet for water is also necessary for replenishing after cleaning, the water being run off by means of a valve, F. G is a small door, through which the trough can be reached in order to clean it out. It is on account of this cleaning out that I should suggest it being placed as low down as possible. You, however, being on the spot, will be better able to judge the most suitable position for it. The smoke, sparks, and gases pass up through A, the steam being divided and deflected downwards by B, as clearly shown; the cinders being heavier than the gas, when once their course has been altered suddenly, will continue it, and fall into the trough of water and be extinguished, while the smoke proceeds upwards through the gauze, which will most probably arrest any few sparks that may have escaped the bath. If you settle on this arrangement, you must first decide where and what diameter A shall be, and all the other contrivances should be made proportional to it, and can be measured from the drawing when you settle the scale, which is the same as deciding the diameter of the chimney, A.—P. B. H.

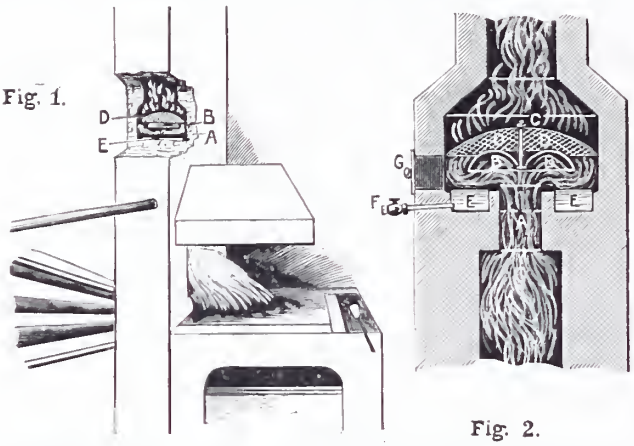


Fig. 2.

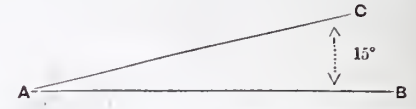
Blacksmith's Forge. Fig. 1.—Hearth and Chimney. Fig. 2.—Enlarged Section through Chimney, showing Spark Arrester.

**Original Designs for Wall Papers and Calico-Printers' Patterns.**—T. W. (*Accrington*). Advertise these in WORK. In the meanwhile, send a few samples, that I may see what you can do.—ED.

**Coal Vase.**—J. T. P. (*Bow*).—I must ask you to explain more fully your query. Do you mean the manner in which they are jointed together, board to board, or some mechanical contrivance? By pivoting, countersinking the pivots, and filling the holes up afterwards, the door or flap could be secured to open as usual without exhibiting the means upon the outside. Is it a collapsible article you allude to?—J. S.

**Spiral Cutters.**—SPIRAL.—I am not much of an authority on spirally grooved cutters. I have not cut many, and those have only been for my own use and not for the trade. I usually make the angle of the spiral about 15° to the plane of the axis of the cutter—that is, if A B is the axis of the cutter, A C, which makes an angle of 15° with it, is the angle of the spiral groove. I have used this rate of spiral on various-



sized cutters with good success. Some makers seem to use a little less. I do not know whether SPIRAL'S set of change wheels is the full set supplied by the makers, but there seems to be sufficient to cut all the different spirals he is likely to require, at all events for cutter-making. Supposing it is required to cut a spiral of one turn in 6 in., that is 6 in. pitch. Now, since the screw in the slide has four turns to the inch of traverse, it must evidently make twenty-four turns while the mandrel makes one. The worm wheel on the spindle has forty teeth, single thread; the worm shaft must therefore make forty revolutions for twenty-four turns of the screw. The change wheels must therefore be in this proportion, 24:40, the larger wheel being on the screw. I think if SPIRAL follows out this reasoning, he will see how to get his wheels for any pitch. Of course, if two wheels will not do, he must compound exactly as in screw-cutting, keeping the proportions the same.—DAMON.

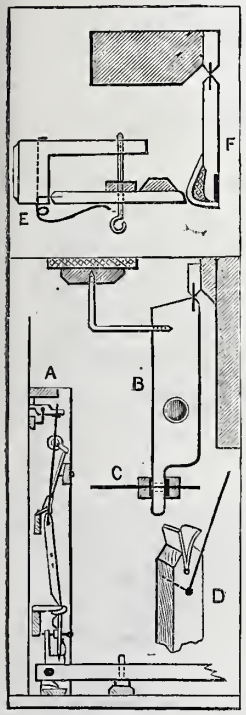
**Galvanic Water.**—READER OF WORK.—You have seen an electrical apparatus in which a basin of water containing a coin was placed, and persons not in the secret were challenged to take the coin out of the water. This they could not do, because the water was said to be galvanised. The basin of water was connected to one pole of a powerful induction coil, and the water thus formed a conductor of the electric current, just like the handle of an ordinary shocking coil. The water was not galvanised, nor is there such a thing as galvanic water. The experiment you saw performed may be repeated by you with one of the coils mentioned in my series of articles on "Induction Coils" now in the Editor's hands, in which such instruments are described and illustrated.—G. E. B.

**Magnetic Saturation.**—C. B. (*Regent's Park*).—The saturation limit of magnetism in best soft iron is 200 lbs. per square inch. It will take 5,000 amperes of electric current flowing through a suitable wire wound over soft iron to magnetically saturate one cubic inch of the iron. In malleable iron the saturation limit varies considerably with the hardness of the metal and its purity. In ordinary commercial iron the limit will rarely extend above 120 lbs. per square inch. In cast iron the saturation limit is lower still, so that a 5,000 ampère current will not magnetise a cubic inch of it beyond a power of holding 100 lbs. The variation in this limit will also be larger than in best soft iron; hence the frequent expressions of dissatisfaction with the results obtained from small dynamos.—G. E. B.

**Power to Drive a Dynamo.**—C. B. (*Regent's Park*).—Find out the total output for which the dynamo is built. If this is expressed in watts, divide the figures by 746, and the product will be the horse-power required to drive the dynamo. If the output is given as so many ampères at a pressure of so many volts, multiply the volts by the ampères, and divide the product by 746 as before. As a dynamo works best when more than enough power is provided, it is safe to allow 10 per cent. for loss in friction and slipping of belts, but this should be increased when small machines having small driving pulleys are to be driven at a high rate of speed. Much also depends upon the width, tightness, and length of the belt. A tight, narrow, and short belt will absorb more power in overcoming friction than a wide and long belt moderately tight. It is not usual to run all the current through a voltmeter and ammeter on a lamp circuit, so as to always read the state of the current on these instruments. They are usually mounted on the switch-board as shown at Fig. 92, p. 837, Vol. II. of WORK, and connections are made with them as required by means of switches, the connections being shown in diagram Fig. 94 on the same page.—G. E. B.

**Zincography.**—LIONEL.—There is such an affinity between zincography and lithography that almost everything that has been already said in the different papers running through the third volume of WORK on "Artistic Lithography," applies equally well to the above branch of the art, the great difference being, as the name implies, that one is

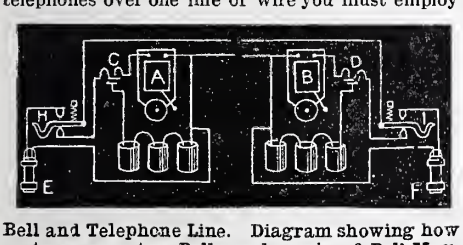
drawn on and printed from a litho-stone, and the other from zinc plates, so I can only ask you to refer to the back numbers for an idea of *drawing* on zinc or stone. To give an outline of *printing* from zinc or stone would take up a great deal too much space in "Shop," as a whole volume might be written on the subject, and to write a brief sketch would only give you, or any other reader, an imperfect knowledge of what is required. One principal thing to be noticed is, that drawing an outline on stone in lead peneil, and working over this a tint, it may or may not print with a white line or space, wherever the peneil has touched the stone; but on zinc the pencil line would print as a solid black line, therefore I must warn the artist to be most careful to put the drawing on the zinc by means of the red chalk transfer paper mentioned on p. 115, No. 112, Vol. III. of WORK. Another thing is that zinc not possessing quite the same qualites as stone, the ink, or chalk, etc., does not penetrate it to quite the same extent, so the artist has to be much more careful in etching the drawing in case of accidents to the work. Damp weather has a great effect on the zinc plates, although in a rather different way to stone, therefore the neecssity of keeping the plates as dry as possible. A preparation of nut-galls must be used instead of nitric acid in etching the plates.—A. J. A.



**Pianoforte Action—A, Section; B, Damper; C, Damper Wire; D, Sticker; E, Hopper; F, Lever.**

**Pianoforte Action.**—W. D. (*No Address*).—The action you have in your piano is known in the trade as the "sticker" action, and I should think it is powerful enough for your piano, as it is probably strung light, or with thinner wire than is used now. Of course, your piano would be much improved if you added dampers and re-hinged the stickers with new leather, also covered the levers with leather in the same manner in which they are covered. I have sent a sketch with letter, which will make plain to you how to attach dampers. I would not attempt to make them if I were you, as you can purchase for 4s. 6d. a set of 60, and if the hinges of the levers are worn out, get a set of new ones made to pattern 1, which will cost you 3s. a set. The dampers are hung with glue on a rail which extends from one upright of action to the other. If you will look at No. 46, Vol. I. of WORK, you will see how to fix damper-rail, and you could fix a soft pedal as described there. Materials you can purchase from Mr. Hallpike, of Mare Street, Hackney, E., who will send you them by parcels post. If you order the dampers, send a rough sketch from mine, and he will understand what kind you require; and ask for damper wires complete. You will see that the damper wire goes through the side of the sticker, then through a hole in the damper, and is fitted with buttons and cloth washers to pull it down. If you think you cannot manage to repair the action, I should send it to the above address, and ask Mr. Hallpike to repair it and add dampers to it. I don't know that I can say any more at present. If you are in difficulty, write again.—T. E.

**Bell and Telephone Line.**—A. B. G. (*Ascot*).—To ring two bells and work two ordinary bell telephones over one line of wire you must employ



**Bell and Telephone Line. Diagram showing how to arrange two Bells and a pair of Bell Magnetic Telephones to work over one Line—A, B, Bells; C, D, Three-way Keys or Pressels; E, F, Bell Telephones; H, I, Automatic Hook Switches.**

two batteries, and connect them as shown in the annexed diagram. To do this, you must employ a three-way key, or pressel, and an automatic hook switch for the telephone at each end of the line. In the three-way key, a brass spring, shaped as shown in the diagram, engages with a hooked spring when at rest, and thus forms a bridge for the current. When the long spring is pressed down on the T contact beneath it, the current is diverted in another direction. The automatic hook switch is also constructed on the same principle, and its form is shown in the diagram. When the telephone is hung on the hook of this switch it is pressed down on the lower contact stud, and connects this stud with the pivot on which the lever of the hook works. When the telephone is off the hook, this lever is drawn by a spiral spring against the upper contact stud, and cuts the bell and battery out of circuit at the same time as it provides a closed circuit for the telephones. When both telephones are hung on the hooks at each end of the line, both bells are placed ready to be thrown into circuit with the batteries on bringing either of the long springs of the key with the T contact pieces. If you wish to ring bell A, the telephones must be hung on the hooks, and the key, D, pressed down; the current will then pass from the battery under B to the spring, D, from this to the under contact of the hook, I, then by the line wire to the hook, H, and by its lower contact across the bridge, C, through the bell, A, and back to the battery by the other line. When the bell, B, is to be rung, the bridge, C, is depressed, and the battery under A is thrown into circuit with the opposite bell. The length of the circuit—that is, the distance of the two bells apart—will make no difference at all to the arrangement of the instruments. If the telephones are to be hung in rooms at some distance from the bells—as in your case, where the bell is in the passage—then have the keys near the telephones, and thus control the circuit. These are little matters of detail which can be worked out by the aid of the diagram.—G. E. B.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Shoe-Mending.**—DUMMY writes:—"Would any reader kindly inform through 'Shop' the simplest way to fix bristles into wax-ends, with a sketch?"

**Engraving on Brass and Metal.**—NELSON writes:—"Can any reader of WORK kindly tell me what course I had better take? I wish to learn the engraving for work on coffin-plates, brass and metal. Where could I get instructions and tools for the same? I am a fair writer."

**Fan-Power for Lathe.**—WORKITE writes:—"Will some reader please give me the sizes of a circular fan (on the Canadian principle) which would have sufficient power to drive a 6 in. screw-cutting lathe, and also instructions and dimensions to make same?"

**Tailors' Cutting and Fitting.**—G. R. D. (*Chetham*) writes:—"Will any reader inform me whether there is a work to be had on tailors' cutting and fitting, where to get it, or any information on the subject, as I wish to learn it?"

**Model Ship-Building, Rig, etc.**—CUTTER writes:—"Will anyone advise me as follows: 26 in. racing yacht, 6 in. beam, 7 in. depth, 8 lb. lead keel, length of spars, how to rig, size of sails, etc.?"

**Paste and Varnish.**—C. R. (*Birmingham*) writes:—"Can anyone give me a recipe for making paste as used by best leather-workers; also the varnish used for delicate-coloured leather goods, and how used? What preparation, if any, is first put on? Also I should be glad of the address of the makers of a patent paste. There is a Company somewhere in London, but I forget the address."

**Market for Fretwork.**—FRETWORKER writes:—"Will anyone kindly tell me if I can sell brackets, etc., when made up, and where?"

**Lucifer-Match Making.**—ANXIOUS ENQUIRER writes:—"Will any kind reader of your valuable paper tell me the various compositions, and how to mix them, so as to enable me to make the common lucifer-match?"

**Paste Diamonds.**—J. H. (*Bury*) writes:—"Will any jeweller reader of WORK kindly give me any information as to how paste diamonds are made?"

**Upholstery.**—SILLY S. writes:—"Will anyone kindly inform me through the medium of 'Shop' the addresses of the best houses to obtain upholstering materials and requisites from?"

**Crib and Dresser.**—JOINER writes:—"Could any reader give me a good design, with all particulars, for a baby's crib (wood); also for a kitchen dresser, the latter to be about 8 ft. in length, or inform me where I could find good designs?"—[JOINER should purchase the indexes to Vols. I. and II., wherein much upon these matters appears.—ED.]

**Maguay Lamp.**—ELECTRIC LAMP writes:—"Will anyone kindly inform me through 'Shop' where I can purchase Maguay's electric lamps?"

**Gas Engine.**—LATHE writes:—"I am contemplating the purchase of a gas engine. Will any brother reader inform me as to the most effective, with the least floor space?"

**Marble Table-Top Stand.**—W. R. (*New Cross*) writes:—"I have an inlaid marble table top, and would thank any reader to kindly give me a design for a stand to it. The size is 2 ft. 8 in. by 1 ft. 6 in. I thought of having it in oak or some other hard wood."

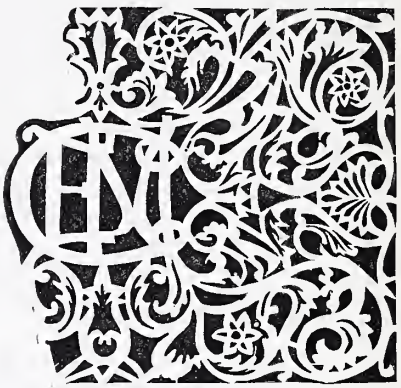
**Bamboo Flower Stands.**—MELTON CONSTABLE writes:—"Can any of your readers inform me as to the cheapest place where I can obtain bamboo cane for making flower-stands, etc., and can anyone suggest an easy method for making the same?"

**Naval Architecture.**—ART T. writes:—"Will any reader name a good, moderately priced book or books on naval architecture as applied to the present time? I have a book by Peake, but it seems too old-fashioned in its matter (timber ships only) and in its manner of stating things and drawings. Are no rules for finding capacity, and other matters, asked for by the Science and Art Department at the annual examination?"

**Fishing-Rods.**—W. J. T. R. writes:—"I shall be much obliged if any reader will tell me (1) what description of cane is used in the manufacture of split-cane-built fishing-rods; (2) where it can be got; and (3) probable price."

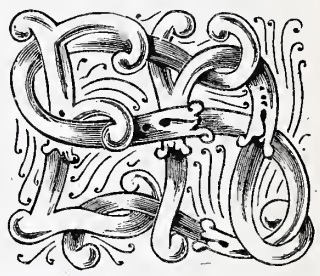
## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Monograms.**—F. J. (*Exeter*) writes:—"In reply to some of your correspondents requiring monograms, I send two, hoping they may suit. The first is for MUGGINS (see WORK, p. 606, No. 142). One of the best methods he can employ to put the monogram E. M. C. on a box is to cut out a design in



**E. M. C. Monogram for Box Cover.**

fretwork, the same size as the top of the box, with the monogram in the centre, and glue it on with a small bead round the edge. Unfortunately, he does not give the size of the box, but this design is suitable for enlarging three or four times. He will see that the initials stand out boldly against the adjoining fretwork, as the latter is of a smaller pattern, which makes the monogram very distinct. I have shown one-half only of the design, but the other part is similar: only reversed, of course. The initials E. H. S. are for G. S. (*Gateshead-on-Tyne*) (see WORK, p. 606, No. 142), for illumination. If the letters are intended to be gilt, where they overlap they must have a dark tint to separate them and throw up the top letter. Shading may be put in similarly, the light being supposed to come from the left upper corner. The ground could suitably be a light blue, with faint white or gold curved lines on it. In these designs I have endeavoured to make the monograms as plain and clear as possible, the ornament being treated as a harmonious accessory, so that one's time is not wasted in trying to decipher them, as in many cases where letters and needless curves are run into each other, and make it extremely doubtful what letter comes first. They ought to be called 'puzzle monograms.'"



**E. H. S. Monogram for Illuminating.**

**Chuck.**—M. (*Bishop Auckland*) writes, in reply to YOUNG TURNER (see p. 590, No. 141):—"If you refer to p. 28, No. 54, of WORK, you will find drawing and description of chuck, which you may make in wood. If there is any part not clear, if you write again I shall be glad to help you."

**Gum.**—W. L. F. (*Dublin*) writes, in reply to GUM (see p. 622, No. 143):—"A good gum for ordinary purposes can be made by dissolving gum-arabic in sufficient warm water to bring it to the consistency required, and when cool, a few drops of oil of cloves or alcohol will preserve a quart from turning sour."

**Horse-Collar Hames.**—F. H. (*Battersea*) writes, in answer to L. M. (see p. 637, No. 144):—"Horse-collar hames are not lacquered, but covered with thin brass, fixed on the rim with a soldering-iron. Any harness-maker will get them re-covered for you. If you had sent your address, I might have told you of a firm near."

**Re-transfer Ink.**—A. J. A. (*London, W.*) writes, in reply to LITHO (see p. 558, No. 139):—"I do not know of any printer who would spend the time in making his own re-transfer ink from plate to stone, as it is one of the things much better bought ready for use; but should you require to make your own ink, then take equal proportions of tallow, wax, soap, shellac, pitch, and litho printing ink, and set on fire the first three, and burn for a quarter of an hour; melt the rest, and mix. Should the ink be still very soft, keep it on the fire at a great heat (without burning) until it is sufficiently hard; the different things should be melted in the above order. If you use varnish and lamp-black instead of the printing ink, then the proportions should be varied to correspond, using more shellac and pitch, as in the first receipt the printing ink already contains these in greater proportions."

**Transfer Drawings.**—A. J. A. (*London, W.*) writes, in reply to DRAUGHTSMAN (see p. 590, No. 141):—"To make a transfer drawing for zincography proceed in exactly the same manner as if it were to be used for stone. You should not use a transfer ink for drawing with, as that is only for the use of the printer. The best litho ink is either 'Lemercier's' or 'Vanymbert's,' both in sticks, which rub on a saucer and mix in the same way as I have already mentioned on p. 66, No. 109, Vol. III. of WORK. It should be of just sufficient consistency to stick to the saucer and not glide off from it. It is not advisable for you to use crow-quill pens; there are special pens prepared for lithography, the best of which are Tillott 290, Somerville, and Mitchell, and if you use either of these pens with the above ink I think you will find your difficulties vanish."

**Glue.**—EDDIFRA writes, in answer to CONSTANT READER (see p. 606, No. 142):—"The best way of preparing glue, and which is used in large cabinet-makers' shops where a quantity of veneering is done, is to get a fruit pan of six quarts, or an iron boiler that is used for boiling clothes, and nearly fill with broken glue; cover with water, and allow to stand twenty-four hours; then place on hot stove, and let a boy stir it and look after it for eight hours (often have I stirred glue that length of time). When cold, there will be no way of cutting it out except by warming chisel or plane irons in hot water previously; then it is placed in ordinary glue-pot, and water added."

**Wool-Working Machinery.**—MESSRS. T. G. AND SON (*Sheffield*) write, in reply to D. G. (*Oldham*):—"We beg to state that the largest makers in the world of these machines we believe to be The Arbey Wood-Wool-Making Machine Company, of Paris, for whom Messrs. T. & W. Cole, London, E., are, or have been until quite recently, the English agents; but we now believe that the firm (Arbey Company) have now ceased to push the trade in England. The North of England Wood-Wool-Making Company, of Leeds, supply a good article, and this firm or Messrs. Cole can give your friend every particular. We ourselves make the knives for these machines."

**Preserving Stone.**—E. H. S. (*Corfe*) writes, in reply to H. L. P. (*Montrose*) (see p. 526, No. 137):—"You ask for a preservative for the stone of a church spire. I may state that a dressing with a liquid called 'Fluate,' obtainable from the Bath Stone Firms, Limited, Bath, has proved successful in arresting decay in stone both in France and England."

**Fire Extincteur.**—THE ASSISTANT ENGINEER, Hackney Union (*Homerton, E.*), writes, in reply to W. L. (*Dalston*) (see p. 606, No. 142):—"I shall be pleased to show or tell W. L. how to charge the same."

**Saw Hammering.**—A. R. (*Scorrier*) writes, in reply to J. S. (*Keighley*) (see p. 606, No. 142):—"The face of the anvil should be a little convex for saw hammering. The best method for saw gulleting is to gullet with the emery-wheel. The fly-press tends to cripple the plate, and merely punches out a piece of steel, leaving the teeth to be sharpened to the bevel required after, while the emery-wheel gives the teeth their proper rake and bevel at the same time the gullet is being ground."

**Continuous Alarum Clock.**—M. W. (*Manchester*) writes, in reply to A. S. (*Lavender Hill*) (see p. 654, No. 145):—"A Mr. Cook, of Shakespeare Street, Manchester, is agent for a new electric alarum clock, which acts for forty-five minutes. I should think this is sufficient. It is quite a new thing, and the clock is removable, and can be used separate from the podestal, which also constitutes the battery or cell. I believe the price is about 16s."

**Alarm Clock.**—F. C. (*Slaithwaite*) writes:—"In No. 145 of WORK, A. S. (*Lavender Hill*) wants to know where he can obtain a continuous alarum clock. I beg to state that Mr. Bassindale, of this place, receives orders for same."

**Tailoring.**—TAILOR writes:—"If APPRENTICE (see p. 654, No. 145) will write to the *Tailor and Cutter* office, 93 and 94, Drury Lane, London, W.C., for their chart and catalogue, he will find the books he requires for all tailor-made garments."

**Upholstery.**—A COUNTRY CABINET MAKER writes, in reply to W. W. (*Notting Hill*) (see p. 590, No. 141):—"I have just seen your query in WORK, and will try if I can help you. I do not know whether your difficulty arises from want of knowledge or want of experience, but you will excuse me if I treat it as being want of knowledge, as I think I can make my explanation clearer by that means. You also omit to say whether your roll is hair, fibre, or alva, and whether the stuffing is single, with roll stretched on (London cheap style), or the old 'first and second stuffed'; but if I describe the latter thoroughly, and you thoroughly master it, you can always modify. I shall therefore take that style with fibre and flock. I will assume that you have got on your web and canvas, or web, springs, and canvas, as the case may be. Now start a row of loops of twine round the edge for the fibre; start from back corner and give about two loops on the sides, and three in front, pointing the needle backwards, so that the second loop begins two or three inches *behind* the end of the first, and so on all round. Of course, you will understand that in all stringing it is only made fast at the beginning and the end, so that each loop can draw upon the others. Now, having your fibre nicely picked, tuck it under the strings evenly, and when you think you have got enough in, go round and regulate it with your fingers till it is nice and even all round; upon this depends the regularity of the work when finished. Then fill in the middle with flock, and put your open canvas (scrim) over, being very careful to get it on straight, for crooked threads are often a cause of hills and holes; then tack it down with temporary tacks to about shape of seat, and then stitch through with a row of twine about 4 in. from the edge all round, to keep all in place. If time will allow, it will be well to go round again, and tack it down more nearly to the shape; but this is not imperative. Then start in middle of front, cut away all waste canvas and turn in with regulator, and put in two or three tacks, about 1 in. or 1½ in. apart; this must decide the height of the pad. Then work each way from these, and keep testing the height by pressing it upright between thumb and finger at the middle and at the point you have reached at the same time, and comparing them; these tacks are not driven home. Then go round it with regulator, and equalise any little irregularities. Next give a row of tack stitching; start at back corner, and fasten twine round first tack, then pass the needle up, but not quite out, and bring the eye point down on the right-hand side of the next tack or next but one; draw twine down, and pass needle up on left hand of same tack, and so on all round; then drive tacks home. Then give one row caught stitch, passing needle up, out at top, and in again about 2 in. back, knotting the first stitch; then, taking about 2 in. each time, bring the needle down just in front of the previous stitch, and loop the twine round it below; this will make a nice even roll if you keep it an equal distance from the edge. Then go round again in the same way a little distance from the edge, and this will make up a little roll about as thick as the finger, or less, and if you have used the regulator well there ought to be no lumps or hills and holes in at all, but a nice even edge all round. This description may seem long and tedious, but I think if you follow it out carefully on one or two seats, you will find that they will come out about what you want, and you can then put less work in if you require to do so; but you will find a little extra painstaking at first will pay in the end. Any further hints I shall be glad to give as far as I can."

**Darning Weaver.**—RALPHO writes, in reply to MART (see p. 621, No. 143):—"You can get the darning weaver from Edwards & Barnes, Broad Street, Birmingham. I do not know the price, but it is quite trifling."

**Mangle Rollers.**—EDDIFRA writes, in answer to LEARNER (see p. 651, No. 145):—"The plan I follow in turning rollers, beech and lignum vitæ, is to procure the rough sawn roller, and bore a hole in each end, by means of an auger, small enough to allow the shafts to be driven in a permanent fixture; the hole in the beech roller may be smaller than the lignum vitæ, as the latter is terrible stuff for splitting. Drive in shaft as true as possible, run in dead-centre lathe, and drive by means of a carrier fixed to shaft. Run lathe as fast as you can without undue shake, and trim down roller with a ⅝ in. or ¾ in. turning gouge; finish off with a 2 in. chisel or a jack-plane iron fixed in wood handle. The ends may be turned true with a lathe cutting chisel —or the safest is a round-nose—and finished with a diamond point, as there is not so much danger of slipping against the iron shaft."

**Steel Springs.**—W. P. writes, in answer to WING (see p. 686, No. 147):—"If he will write to me, William Park, 8, Cobden Street, City Road, Hulme, Manchester, sending rough drawing and all particulars, and gauge of thickness, I will send him prices."

## V.—LETTERS RECEIVED.

## CHICKEN-REARING APPLIANCES: HOW TO MAKE AND USE THEM, ETC.

BY LEGHORN.

TESTING EGGS—TIME OF INCUBATION—REARERS—COOP AND RUN—FOOD UTENSILS—MANAGEMENT OF CHICKS—AILMENTS AND REMEDIES.

*Testing Eggs.*—As promised in my last article, I will, before describing the construction of rearers, etc., give instructions for testing eggs at various periods of incubation, which will apply to both the natural and artificial methods. It will be best to test them after dark by means of a piece of cardboard or similar opaque material, in which a hole the shape of an egg, but slightly smaller, has been cut, using a strong light behind for illumination. Taking the card in one hand and the egg to be tested in the other, held (between the thumb and forefinger) over the hole previously cut, all extraneous light being now cut off, we can see almost through the egg. Experienced operators can distinguish fertile eggs from infertile or clear ones at four days, but the tyro will do well to leave them until the seventh day, when, if fertile, they will have something of the appearance of Fig. 1: a semi-opaque central spot (the germ), from which the blood-vessels, in the form of spidery arms, radiate in all directions. If this appearance is absent and any egg looks clear throughout, it should be removed and, if necessary, replaced by a fresh egg, previously warmed as before mentioned. Infertile eggs removed from the incubator are quite good enough for cooking purposes, or even for eating if anyone is partial to the taste of a "new-laid Frenchman," or may be put aside as food for the young chicks. If the eggs are dark or thick-shelled there may be some difficulty in forming a definite opinion as to their fertility, and in such case it will be well to leave them for a few days longer before discarding them. By the thirteenth day they should have the appearance of Fig. 2, at which stage the embryo chick may be said to live, and from which time development is rapid. Fig. 3 represents a good egg of twenty days' incubation, by which time it is almost entirely opaque, the head of the chick being plainly visible, and in a good many cases its chirp and tap, tap against the side of the shell can be distinctly heard. An addled egg—that is, one in which the germ had lived, but from some cause had died and putrefied—is represented in Fig. 4. A large dark central mass, shifting with every movement of the egg, and suspended in a cloudy liquid, is its characteristic.

*Time of Incubation.*—The egg of a hen takes 21 days, pheasant and partridge 24, duck and turkey 28, goose 30.

*Rearers.*—Now we come again to the constructive part. Rearers should always, if possible, be made round. If square, the chicks are very apt to crowd together into the corners for warmth, sometimes suffocating the weaker ones. With round appliances no such trouble can occur. A capital machine can be made from a cheese-box, obtainable from most provision merchants for about 2d. or 3d. Look out a sound one, with a decently fitting lid. They are of various sizes; one about 16 in. in diameter and 9 in. deep will house about five-and-twenty chicks. It is not advisable to keep a larger number than this together, and on no account should birds of various ages be put together, or it will probably be a case of the survival of the *not fittest*, but *strongest*. We have the choice of two methods of heating—by hot water and by direct heat from a lamp. I use both, but cannot claim any particular advantage for either over the other. With the first-named method there is no danger of chicks perishing through cold should the lamp go out at night, as there would be sufficient heat stored in the tank to last for some hours.

On the other hand, with a direct heating arrangement there need be no fear of drowned chicks through the tank giving way, and no bother about filling or renewing tanks. I think, perhaps, I should give the preference to "hot water" in cold weather and "direct heating" in warm. In Fig. 5 (following the thick lines only) I give a section of a direct heating arrangement, in which A is a cylinder of metal (a large tin canister, about 5½ in. in diameter and 4 in. high, will suffice) fixed to the bottom of our cheese-box, a hole sufficiently large to admit the lamp being previously cut.

Now make or procure a funnel, B, and secure same to the lid in a central position over A. The hole in lid should be cut ½ in. larger in diameter than the size of the top (inverted) of funnel, to prevent the heated metal being in contact with wood, and also to provide ventilation. Two or three ⅂-shaped straps must be riveted to top of funnel, and the latter by these fixed with screws to the lid. No "soft tommy," or ordinary tinman's solder, must be used in this funnel, but if soldered, threepennyworth of silver solder should be procured, the soldering being done with a blow-pipe, using powdered borax as a flux. A small radiator, C, hung from the top by a wire or piece of small chain, will economise heat by radiating it against the sides of the funnel. A small burner, taking a half-inch flat wick, will serve to supply the required heat, and should be mounted on a flat reservoir, as shown in Fig. 5, and as previously described for incubator lamp. Select a burner where the flame will be as far away from the oil as possible, to minimise the chance of the lamp catching fire.

This same design can be applied to the hot-water method, a tank, as shown by dotted lines, being fixed under the lid. A round stamped steel baking-dish will answer the purpose (of course, zinc or copper will be preferable, and last longer), and should have a sheet of tin plate or galvanised sheet iron soldered to the top, leaving a rim or lugs for fixing, as shown at F, F. Cut holes as required, and solder in the cone, E, and provide a pipe in the top for filling. In this case ordinary solder will answer our purpose to all parts where protected by water.

If an outside boiler is preferred, it can be arranged as shown by dotted lines on the right-hand side of Fig. 5, in which D is a small hollow cone, 2 in. diameter and 2 in. deep. This should be made of copper, and have a flow-pipe carried from the top—with the inside of which it must be soldered flush, to prevent air trapping—well into the centre of the tank, and a return-pipe at the bottom, issuing from the bottom of tank. The lamp is then placed in position under the cone, the water in which is quickly heated, and immediately passes by the flow-pipe into the tank. Colder water, entering at the bottom, is again heated and passed on, thus keeping up a continuous flow as fast as its temperature is raised by the lamp. The reason for carrying the flow-pipe into the centre of tank is to prevent the hot water issuing from it from being drawn immediately down to the return-pipe, and thus leaving a large bulk of the water cold. By arranging the pipes as shown, regular and steady heating will follow. One point I must mention: and that is, let the flow-pipe have a slight rise from the boiler and the return a fall to it. A reference to the sketch will make this clear.

Whichever plan we adopt, we shall, after selecting our box, require to cut an entrance, E, 5 or 6 in. wide and about 3 in. high, and over this, on the inside, tack a piece of felt or baize, F, large enough to cover the opening, and cut into lippets to allow the chicks ingress and egress. We now require an alighting board, H, or front doorstep, and for this we shall want a piece of ½ in. deal, about 8 in. by 5 in. Round the edges and corners, and fix it to the bottom, below the entrance, by means of screws. Two fillets, J, 2 in. by 1½ in., and about 14 in. long, fixed across the bottom will keep the rearer off the ground, and also provide space for the lamp reservoir.

If the hot-water arrangement is followed, we shall also need three or four distance-pieces, P, to secure the tank to the lid, which may be about 3 in. long, and 1 in. by 1 in. in section. Holes for lamp, etc., having been cut, and all fixed in position, a couple of coats of paint will improve its appearance and durability. Before moving our family into their new house, we must provide some bedding, which may be hay, straw, chaff, or any warm material, but avoiding fabric of every kind. Straw makes about the best bedding material if cut into short lengths, and rubbed between the hands till soft. Whatever is used, it must be frequently changed, and on no account allowed to become foul, or disease will assuredly ensue. The quantity of excrement deposited by a brood of chicks in a single night is enormous, compared to their size. Cleanliness in every operation of chicken rearing cannot be too highly estimated.

Fig. 6 shows Winchcombe's patent hot-water machine for outdoor use, fifty chick size, with special wind-proof lamp. Another size, for twenty-five chicks, is made for indoor use. They answer the purpose for which they are intended as well as many of higher price. The one I use works very satisfactorily, the maximum heat obtainable with the lamp turned full up being 90° Fahr. It has a deep tank fixed to the lid and an outside boiler, the inner case of which also forms the lamp chimney, a special burner being used, which fits well into the bottom of chimney shaft, thus doing away with the trouble of broken glasses. The oil reservoir is large, holding sufficient fuel for three days' supply. The lamp burns for forty-eight hours without attention, will not catch fire, and only costs about 3d. or 4d. a week for oil.

A cold brooder to take the chicks after removal from the rearer can be made from another cheese box (if somewhat larger all the better), and needs no internal fittings or furniture beyond bedding.

*Coop and Run.*—Fig. 7 illustrates a very handy coop and run, which may take the place of the cold brooder if the chicks cannot be allowed their liberty—in fact, it might be so used from the first by placing the rearer inside the coop, the run then proving a safeguard against depredations of the feline species. A range of three or four of these coops, etc., may with advantage be built together, and thus effect a saving in cost over the same number built separately. They will always be useful as pens for isolating cockerels, birds preparing for the show-pen, or suffering from infectious diseases.

A useful size for the coop will be 2 ft. square by the same height at back, and 6 in. higher in front. The run may be 4 ft.

long, 2 ft. wide, and 14 in. high. If the purse is low, and strict economy has to be studied, a suitable packing-case may often be obtained for a trifle, which can easily be adapted to suit individual requirements; but if eleganee and some degree of finish are aimed at, what is known as "match-boarding" will make a comfortable house, each board being tongued into its neighbour. Draughts will be excluded, with benefit to the inhabitants.

The whole of the back should be hinged to form a door, "cross garnets" being used for the purpose; a hole cut in front for access to the run, and provided with a drop shutter for use at night, and ventilation holes must be bored at the top of front, as shown. Slate batten, 2 in. by 1 in., is just the thing for the run, costing about 2s. 6d. per 100 ft. run. After being planed, the rails should be mortised and tenoned, or halved, painted, and covered with ¾ in. galvanised netting. The roof of coop should be covered with stout unbleached calico, closely tacked under the edges, and well painted, when it will last a long time without repairs. If it is desired to cover the run as well, it will be advisable to alter the pitch of roof, and slope it to one side instead of to the back, as shown.

For coop, as shown, we shall require, say, 48 ft. of 6½ in. by ⅝ in. match-boarding, and 20 ft. of batten as ledges, to secure the boards together; and for the run we shall want another 30 ft. of batten, making 50 ft. in all (these quantities allow for no waste, so allowance must be made in buying), and 18 ft. of 12 in. galvanised netting, or 10 ft. of 12 in. and 4 ft. of 24 in.

*Food Utensils.*—As chickens, if left to their own devices, will trample their food under foot and foul their water, it is necessary to take some special precaution that this is not done, as besides the waste occasioned, the scattered particles of food are apt to get sour or tainted with excreta, in which state they become highly dangerous. Prevention being better than cure, it will be an economy to provide a guarded feeding stage, as illustrated in Fig. 8, which consists of a base of wood, say, 8 in. long and 3 in. wide, to which wires are affixed, about ¾ in. apart. To bend these regular, a gauge will be necessary, which can easily be constructed, as shown in Fig. 9. A piece of wood is eut to shape as shown, 3 in. wide and about 3 in. high. This is fixed to another piece of handy size, and a screw or nail, N, fixed as shown. The thick black line is intended to represent the wire bent on the gauge, and is almost self-explanatory. Pieces of suitable stout wire are first cut to length, one end inserted between the gauge and the screw, then bent round to shape, giving a few taps with a hammer at the angles.

Having the bent wires ready, bore holes in the sides of baseboard, into which the wires will fit tightly. A few blows with a hammer will now make all secure. The food can (and at first should) be sprinkled on the board, or placed in a pan or trough, made of tin or zinc, to fit under the cover. Water can be protected by the same means, but I much prefer to use a small poultry fountain of glass or glazed earthenware, which can be procured for a small outlay at most china warehouses.

*Management, Feeding, etc.*—As soon as the chicks are hatched, they can be placed in the rearer, which should be well warmed, and kept during the first day at about 90° Fahr. It will also be well during this period to stop up the doorway. Leave them alone for twenty-four hours, during which time they will require no food, being sustained by the absorption of the yolk into the abdomen, this being the last operation before leaving the shell. One special word of advice—Don't follow the stupid and useless plan of ramming a peppercorn down their throats as soon as hatched, and don't attempt to remove the horny excrescence at the tip of their beaks. It is a natural provision to protect their soft and delicate bills, and will disappear naturally when no longer needed.

The first meal should consist of bread-crumbs, moistened with a little dripping, and mixed with grated hard-boiled yolk of egg. This course will do during the first day, after which egg should be excluded, and their diet varied as much as possible. Any of the prepared meals sold for poultry can be used, Spratt's being very good for the purpose, although somewhat expensive. From the first, for the last meal at night some grain food should be given, starting with coarse oatmeal, following with canary-seed, of which they are very fond, then bruised corn, and finally, when large enough to take it, the whole grain. A little animal food given daily is a necessity; and if only a few are kept the scraps from the table will suffice, but if a large number have to be fed something additional must be provided.

Spratt's "Crissel" (granulated meat) is very suitable, and is much relished. Green food must always be given if the chicks do not enjoy a grass run, and may take the form of chopped grass, dandelion, onion, lettuce, etc. A supply of grit is also a necessity, and a sprinkle of bone-dust over their soft food will be a preventative of diarrhœa and leg weakness. Boiled rice (get Patna), with a little milk, will also act as a check against the former, but should not be given sloppy. Never leave food about to become stale. As soon as they have finished feeding, remove the feeding vessel until the next meal-time. As to whether water should or should not be given, I will not venture a decided opinion; but if it is given, it must be pure and frequently changed, so as not to become stale. I believe that mortality among chickens could, if traced, in the largest number of cases be attributed to impure water. As the chicks grow, the quantity of food given must be increased, and the intervals between times of feeding lengthened. Every hour during the first week will not be too much, whilst at four weeks four meals a day should suffice, being further reduced to three at two months. For the first week, the heat of rearer should be about 75° Fahr., and gradually decreased until the third or fourth week, when, according to the state of the weather, it will only be necessary to supply it at night; and after the sixth or seventh, if the weather is favourable, it may be entirely dispensed with, and the brood transferred to the cold brooder or coop. I have not space to treat on the subject at length, so for additional information I must refer my readers to one or other of the numerous treatises on the subject.

*Chicken Ailments.*—Just a word, and I've done. With proper care and attention, illness should be unknown; but in case it should occur, I will just touch upon the symptoms of and remedies for treatment of the most common.

*Gapes* is a disease I have never been troubled with, but once get it among a brood, and it is difficult to eradicate. It is caused by a small worm, which infests the windpipe, causing the sufferer to gasp or gape for breath; hence the name.

Remedy: A little carbolic acid should be placed in an iron spoon and held over a candle. Into the fumes given off the head of the affected bird should be held until suffocation almost ensues. This will dislodge the worms; and, if carefully done, the chick will be none the worse—left alone, it will surely die.

*Roup* is a severe cold, and takes the form of a running at the nostrils, ruffled plumage, and loss of appetite.

Treatment: Isolation and warmth, and a course of Vale's or Cook's roup pills or Spratt's roup paste. A severe case is, generally speaking, incurable.

*Diarrhœa.*—Caused by stale and sour food, dirty water, and want of cleanliness.

Boiled rice, sprinkled with powdered chalk, will generally give relief; if severe, two or three drops of chlorodyne in a teaspoonful of water will generally prove curative.

*Leg Weakness.*—Heavy, fast-growing birds, especially cockerels of the larger breeds, are sometimes subject to this, but if bone-dust is used during rearing, it will rarely occur.

Treatment: A stimulating food with meat.

My task is finished. To all whom it may concern, I would say, "Go in and prosper." Poultry rearing is a profitable and interesting hobby; and these papers may, I hope, induce some who do not at present keep fowls to commence to do so forthwith. I am always ready, through "Shop," to help and advise anyone in trouble, and shall be pleased to smooth away any difficulties that may arise.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

GARDEN ARCHES: EFFECTIVE UTILITY OF ARCHES—ARCHES IN ONE FRAMEWORK—ARCHES COMPOSED OF TWO FRAMEWORKS—TOP UNITING IRONS—TWISTING ZINC RIBBONS OR RODS—MACHINE FOR IRON RIBBON TWISTING—THE WORKING OF THE LATTER—THE CONSTRUCTION OF THE LATTER.

**Garden Arches.**—These are effective and useful. I have very great admiration for the pretty effects obtained by the use of garden arches when they are covered and completely hidden from view by creeping plants, etc. A few of them fixed over a path at very short distances from each other, and entwined with Nature's adornments, will produce a pleasant shady spot for the leisure hours to be spent within; the sun or the moon peeping through the interstices above will bring up memories when one strolled through the country lanes, with the overhanging branches forming natural arches. But there is a far greater pleasure to be gained oftentimes by passing the hours away in our own gardens, as outsiders are not allowed to trespass; whereas in public walks one is always open to the intrusion of men and vehicles.

No necessity exists for a garden arch to be of elaborate construction. What is required is little more than a framework up and around which plants may be properly trained, as the latter should completely hide the former. Fig. 171 is a sketch of the most ordinary pattern made, and Fig. 170 represents one of slightly more pretentious appearance. These are sometimes made in two parts, sometimes in but one only. They are half-circular at the top. It will require very little arithmetical ability to arrive at the extreme length of one of these

articles if the height and width are given. A size they are frequently made in is 7 ft. high, 4 ft. wide, and 1 ft. deep at the sides. In these measurements I have not included the stakes at the ends; these are for the purpose of fixing them properly to the ground. I will deal firstly with those made in single pieces.

*Arches in Single Frameworks.*—These are formed of a pair of long rods to which are meshes used vary to a great extent. It is the endeavour of most workmen to so place the work that the junction of the meshes on one side are situated as nearly as possible against the long rods, as in Fig. 172, and also to have the stay-bars in such a position that they as well will cover junctions (Fig. 177).

When the piece of work is ready, the wires are turned over at odd intervals to

Figs. 170, 171.—Alternative Patterns of Garden Arches. Fig. 172.—Arch before being bent; not necessarily representing Arch in Fig. 170, as the latter is supposed to be in separate halves, some being made whole and others in halves.

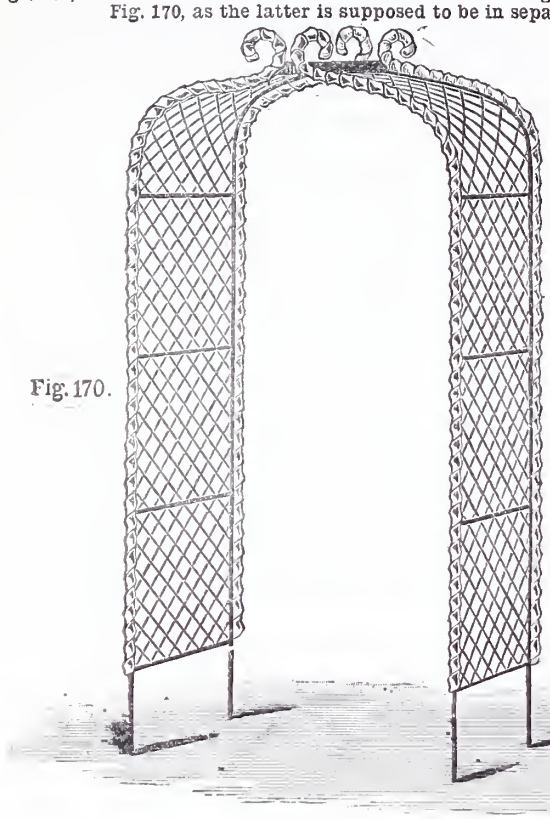

Fig. 170.

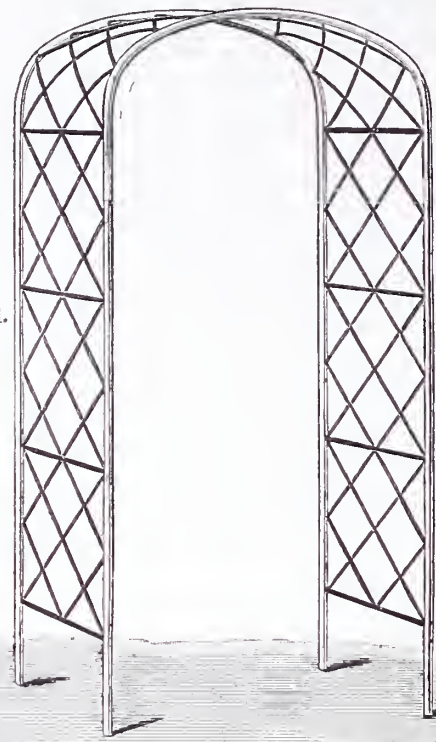

Fig. 171.

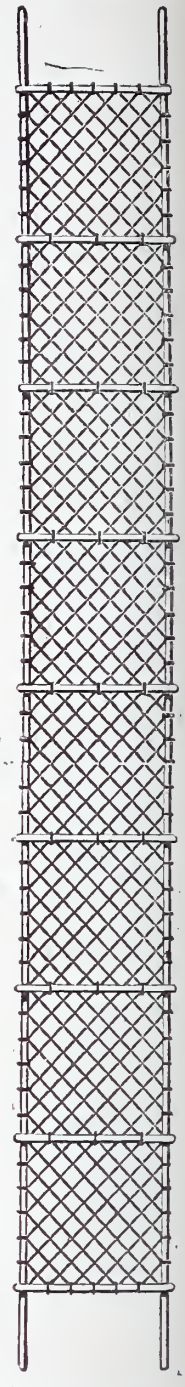

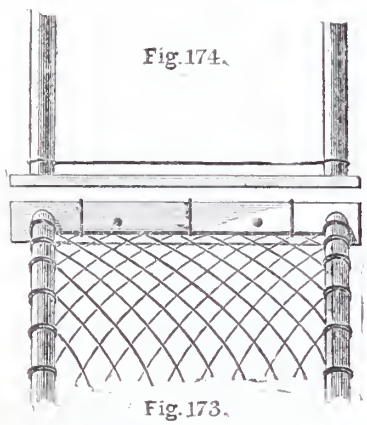

Fig. 174.

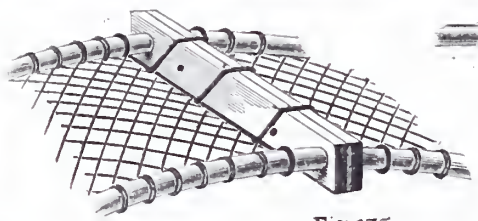

Fig. 175.

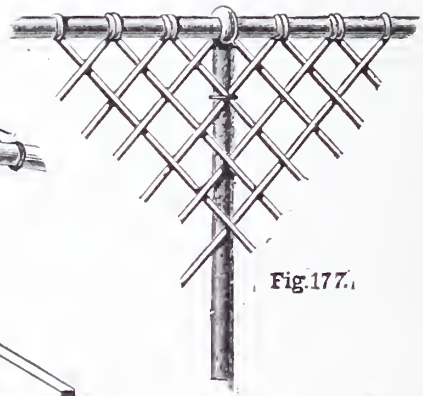

Fig. 177.

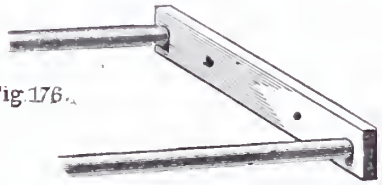

Fig. 176.

Fig. 173.

Fig. 172.

Fig. 173.—Appearance of Fig. 175 when viewed in Elevation. Fig. 174.—Plan of Framework of Fig. 175. Fig. 175.—Perspective View of Top of Arch when made in two separate halves. Fig. 176.—Perspective View of Fig. 174 minus the Cross-Wire. Fig. 177.—Enlarged Portion of Fig. 172, showing how Cross-Bars are attached.

secured stay-bars of the required length, as shown in Fig. 172. There are usually about nine of these. A portion of each long rod is left free to act, as before said, as a stake. The longer these free portions are, the stronger will be the hold they will afford the arch when the latter is fixed; but 1 ft. lengths will be very suitable.

When more than one arch of the same description is to be made, the number of meshes contained in the first one is noted, and taken as a guide for cutting out pieces of work for after use. The number of hold it in position for the final turning over. The wires are then secured to the stay-bars by being tied to them in about three places each. When thus far ready, the whole is carefully bent in the middle round a cylindrical object, and the arch is finished, with the exception of the galvanising, painting, or whatever process it is intended it shall undergo.

*Arches composed of Two Frameworks.*—Frequently these articles are made in two separate halves. Each half is at first a flat frame; each has two projections at one end for purposes named in connection with the one spoken of above, and at the other end there is a flat iron with two holes in it. They are each bent in such a manner that a proper arch results when two are placed together in a reverse position, with the two flat irons exactly in the middle of the arch, where they will be fastened to each other by means of screws and nuts, and thus make the whole a solid job. But before this point is reached I must say more concerning the turning over of the wires.

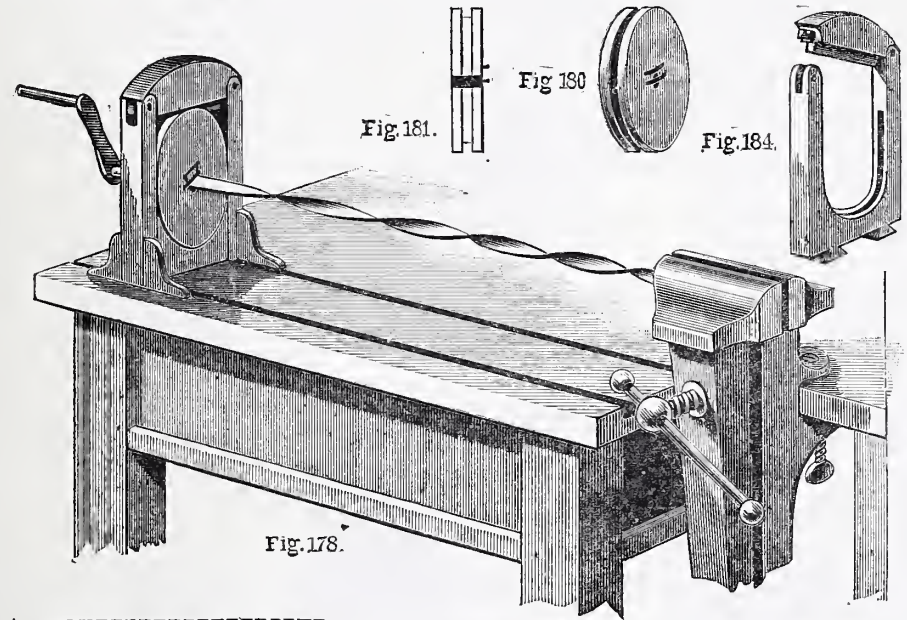
*Top Uniting Irons.*—It will be understood that at the ends where the flat irons are the wires cannot be turned over on to them. To overcome this, a wire of the same gauge as those composing the meshes of the arch is fastened to that end of the frame, leaving a small space between itself and the flat iron. Over this the wires can be conveniently turned. After this operation, the single wire is bound to the flat iron in two or three ties by a piece of wire being bent over

both at each point, as in Fig. 173, in which diagram it is supposed a side elevation is shown of the frame when arched.

The same particulars as those dwelt upon above will apply also to the arch shown in Fig. 170. The difference is that the meshes are smaller and the article is ornamented by having twisted iron rods or ribbons fixed to it by means of wire ties. These are made in various degrees of twists.

**Twisting Iron Ribbons or Rods.**—A method of twisting these rods, which are originally flat, is by fastening one end in a vice and one end between a pair of pincers, and turning it regularly and carefully. But the machine which I show in Fig. 178 will be acceptable to the workman using it, both on account of the advantage of performing the work much quicker and much more symmetrically than could be accomplished by hand.

*Machine for Iron Ribbon Twisting.*—One end of the iron ribbon is passed through a pair of catches on the wheel (Fig. 180), while the opposite end is held firmly between the jaws of a vice. The wheel is turned sharply, and the ribbon is consequently gradually twisted, as represented in the drawing. It is obvious that at each twist or turn the distance occupied by the iron between its two ends proportionately diminishes. Therefore, allowance must be made for this shrinkage. This is accomplished by permitting the machine to travel within a couple of grooves in the bench. Thus, when being used, the iron as it diminishes in length draws the machine nearer and nearer to the vice, thereby making all necessary allowance. To retain the appliance continually in direct contact with the bench, it will at once be seen that dovetail grooves, as in front elevaton, Fig. 179, will be advisable, in which may travel the bottom dovetails of the machine. Something also is needed to keep the device always perpendicular, and this something is found in the shape of two pairs of brackets, attached in such a manner that their bottom edges are in loose or free touch with the surface of the bench.



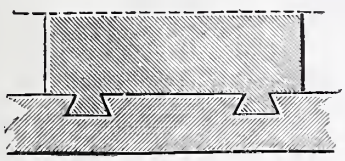


Fig. 179.

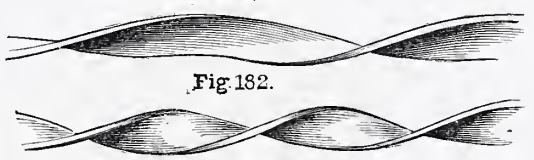

Fig. 182.

Fig. 183.

**Fig. 178.—Machine for twisting Iron Ribbons. Fig. 179.—Elevation or Section of Bottom Part of Machine and Bench, showing Dovetails, etc. Fig. 180.—View of Wheel of Machine. Fig. 181.—Section of Wheel. Figs. 182, 183.—Appearance of Ribbon or Lathing whilst being twisted. Fig. 184.—Standard of Machine.**

*The Working of the Machine.*—It will be expedient that the jaws of the vice meet and hold the end of the iron ribbon *exactly* opposite to the catch in the wheel, otherwise the twist may be irregularly made.

Space necessarily confines the piece of imaginary iron supposed to be undergoing the operation of twisting, in Fig. 178, to a very short piece; but it can, of course, be understood that any length may be turned by it, provided sufficient accommodation is supplied.

While using the machine, it will be well to hold it by one hand at the top, in order that it may not be drawn too quickly in the direction of the vice, for it will be noticed that frequently the ribbon will present symptoms of following a "barber's-pole" appearance—that is to say, instead of twisting as it should, it will appear inclined to bend to the same shape that it would be seen the red line of a barber's pole does if the same could be taken bodily off the pole.

It will be observed that there is a recess in the bench to accommodate the vice, so that the ribbon may stretch away from the machine precisely at right angles to it, thus allowing the vice end to be opposite to the catch.

In Fig. 182 a section of the ribbon is shown twisted to a certain degree, and in Fig. 183 it is represented after having further undergone that operation. It is not an essential matter concerning the degree of the final twisting, as workmen use their own opinions of the effects to be obtained. Many would deem that in Fig. 183 quite satisfactory; many would consider a closer twist preferable.

*The Construction of the Machine.*—Perhaps I may now particularise the details and construction of the machine. It needs no telling that it will be best if made in metal; but hard wood, lined with metal on those parts where friction will result—and there will be plenty of it occasioned by the revolutions of the wheel—may be used with comparative utility as substitutes. In Fig. 184 is shown the main portion of it. It matters little whether this consists bodily of one piece, or is formed by two uprights dovetailed at the bottom, and joined together by a cross-piece shaped half-circular on its upper edge.

Around the half-circular portion of the inner edge should be fixed a runner or a projection. This ought in all reason to be of metal. At the top of each upright is a deep notch or mortise, into which will be pivoted one end of a top rail. The outside surfaces of this rail should be flush with the surfaces of the portions to which it is pivoted. It will therefore be necessary to have small tenons on the ends of the top rail. To retain the free end when required, it will only be needful to run a pin through the holes in the upright and through the particular tenon between them. Along the middle of the top rail, at the bottom of it, will run a projection of the same depth as that upon the inner edge of the standard.

The wheel is grooved completely around its circumference, as in section, Fig. 181. This wheel is then fitted over the projection on the inner parts of the main portion of the machine, and is retained thus when the top rail is lowered into position and secured. The handle will, of course, penetrate the wheel through the centre. The larger the handle, the easier and quicker will the use of it be found; but it will be unnecessary, perhaps, to say that it must not be too large, otherwise it will be prevented from revolving by colliding with the bench. It is on this account that I have shown the machine as of rather large dimensions proportionately compared to the drawing of iron ribbon, etc.; for, no doubt, it can be comprehended that a very tall machine will permit of the introduction and use of a deep handle.

Exactly outside the centre hole of the wheel there will be a catch, simply consisting of a piece of iron bent and driven into the wheel in such a manner as to allow the zinc to pass underneath it, as does a strap under a buckle. Parallel to this, at a short distance from it, will be another catch exactly similar to it, to permit the iron to have a firmer security by being bent around it in addition to the first mentioned.

If the grooves in the bench are open completely to the end of the latter, the whole of the machine may, when not required for use, be taken from its position, in order that it may not by its presence be an impediment in the way of jobs which do not need its aid; whereas, if the ends of the groove are closed in, it must be apparent that the machine must always remain and be a source of inconvenience upon the bench.

In another paper or two my subject must be brought to an end here, although much yet remains to be said about machines, appliances, processes, ways and means used and resorted to in wire-working. The art is a useful one, and deserves to be known and practised far more widely than it is, and especially by amateurs who have a turn and liking for practical work.

## SIMPLE HEATING APPARATUS.

BY THOMASO.

A CORRESPONDENT, J. D. (*Arran*), wrote for information on a subject which could not be given intelligibly within the limits of a "Shop" answer. It has therefore been necessary to put it in the form of an article. But as the answer (while it may be useful to other readers) has special reference to the needs of that one correspondent, it has been judged advisable to let the article retain the phraseology of a "Shop" answer, otherwise it would scarcely be apparent to the general reader why one particular case was treated of and other contingencies merely glanced at.

Our correspondent wants to warm a bird-room which has no fireplace, by means of oil, without vitiating the air, and he says he has tried the ordinary paraffin stoves, but they fail in that one particular. I must assume that, there being no chimney, the ventilation is provided for in another way. Now, there are two ways in which the room can be warmed. The first is to have an oil warming stove in the room with a sheet-iron pipe over it, to carry away the fumes to the outer air. I expect the pipe was omitted, hence the vitiation complained of. This arrangement is very simple, particularly as there are windows in the roof. The pipe can be bought ready-made in lengths. One end of the pipe rests on the top of the oil stove and the other goes straight up, and out through one of the windows. A pane of glass must be removed, and a piece of sheet iron, with a hole through it large enough to admit the pipe, substituted. On the top of the pipe a large cone is placed, to prevent rain or snow beating down, and if the other end of the pipe is too small to cover the top of the stove where the heated air escapes, it must have a funnel-shaped piece attached to it large enough for the purpose. The different pieces of the pipe are joined by tapping the end of one inwards until it is small enough to enter the end of another piece, when it is riveted in place. By this method the iron pipe is made the heating agent. It gets hot, and gives out its warmth to the air in the room, none of the heated vitiated air or smell from the lamp escaping. Heated iron always gives out a more or less close smell; but in the present case it will be slight enough to be disregarded. The pipe is of course unsightly; but it cannot be helped. Blacklead it if it is not galvanised. Use no paint or varnish, or it will smell for a long time.

The other arrangement is more ship-shape, and consists of a simple portable (or otherwise) hot-water heating apparatus, which you can easily make yourself if you can use the soldering-iron. The general arrangement is shown in Fig. 1. A is a small boiler of stout tinned plate, which is shown in section in Fig. 2. The chimney is 2 in. in diameter, and after rising a short distance above top of boiler, it is bent sharp back and taken out through a hole in the wall, then turned up for a little distance, and the end covered with a cone. The other dimensions of the boiler are unimportant. Height may be a foot, and outside diameter 7 in. or 8 in. One thing must be kept in mind: viz., the object to be attained is to expose the greatest amount of surface to the heat of the lamp, and at the same time have as little water space as possible. I do not expect your warming-stove lamp will do for heating the boiler. Get a small oil cooking lamp having a double-wick burner, if possible, or at any rate one with a wick as wide as possible. See that it is not too far away from the level of the bottom of the boiler, or it will not warm the water sufficiently. Support the boiler on anything uninflammable which has a hole in the top large enough to expose the boiler to the heat of the lamp. Into the side of the boiler solder two tubes of tin plate, to the ends of which brass flanges have been soldered. These flanges are subsequently screwed or bolted (with red lead between) to corresponding flanges connected with the hot-water pipes. If you do not anticipate having to move the concern, it might be soldered together instead of using the flanges. The pipes are made of thick tin plate or sheet zinc, and may be 3 in. diameter. I think a total length of 9 ft. or 10 ft. (excluding the uprights) will be enough for your purpose. You may divide this length into three or four, if more convenient. Zinc is an unusual metal to use for hot-water pipes, but I cannot see any objection to it other than the corroding of the metal where it comes into contact with iron or copper, owing to galvanic currents being set up. Zinc is freely used for toilet jugs and cans meant for hot water, and an old zinc-worker

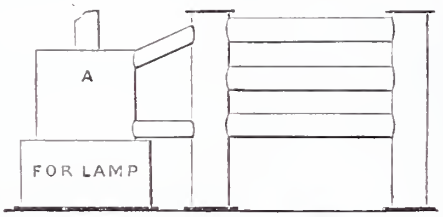

Fig. 1.—Simple Hot-Water Heating Apparatus, complete.

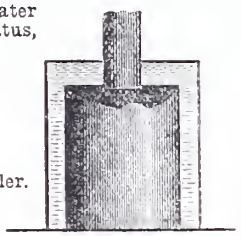

Fig. 2.—Section of Boiler.

tells me he has made hundreds of feet of zinc hot-water pipe in his time. Zinc is to be preferred to tin plate, as it does not rust. It must not, of course, be used for the boiler.

The uprights may be round or square: round is easiest. They must be larger than the other pipes, as a matter of convenience when joining them together. One upright will be wanted about every 3 ft. On the top and bottom of each solder a flat piece of metal, the bottom one projecting all round, to allow of the apparatus being screwed to the floor. You can put the pipes at any height you like, bearing these rules in mind—no part of the lowest pipe is to go below the level of the bottom of the boiler, and no part of the highest is to go below the level of the top of the boiler, the principle of the thing being this: hot water is lighter than cold, and therefore ascends to the highest point of the apparatus, while the cold water rushes in to take its place at the bottom, and is in turn heated and goes up aloft. And so the circulation of the water is kept up.

In the top of the upright, farthest from the boiler, make a round hole, and fit a sort of flat kettle-lid to it. The little steam that escapes will serve to keep the air from getting too dry. If it is objectionable, let the steam escape to the open air by way of a small pipe. For a greenhouse, for instance, the steam would be rather an advantage than otherwise.

The heat is of course regulated by turning the lamp up or down and opening ventilators. The water must always be kept high enough to entirely fill the top pipe. Examine it frequently.

Paint the whole appliance with some dull black paint, such as vegetable black and gold size diluted with turps. A dull black surface radiates heat better than a bright shining one. Before painting zinc, roughen it all over with coarse emery-cloth, or the paint will peel off.

If you increase or decrease the size of the pipes, increase or reduce the total length correspondingly. If preferred, you can have only two long pipes, and carry them along one side of the room on supports fixed to the wall, and thus save the trouble of making uprights. Of course, the two pipes must be joined at the end farthest from the boiler, and they should gradually rise so as to have the highest point of each as far from the boiler as possible. A very slight rise is sufficient. If you like, you can, of course, put lamp and boiler outside under a small shed, and carry the pipes through the wall. There is no possible chance of air vitiation then.

Whatever warming apparatus you decide on, be sure and have plenty of water about the room in shallow bowls or trays, otherwise the air will get so dry that the birds will suffer. You might put their drinking water in shallow zinc trays. They like to paddle in it, and it would thus be—

"Contrived a *triple* debt to pay."

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Mouldings, Chamfers, and Beads.

WE have hitherto dealt with the plainest of construction, but as nothing is made without some effort to please the eye, we will consider mouldings as a relief lesson, for mouldings are themselves a relief to the squareness of construction, which becomes tiresome to the spectator if too unbroken. Moulding in wood-working is a misnomer; but as the term is well understood, we will not trouble ourselves on that point. A dictionary definition is: anything cast in a mould, or as if so; a projection beyond a wall, column, wainscot, etc. Clearly this meaning supposed something built up, whereas our mouldings are produced by wasting the superfluous wood.

The simplest moulding is that known as a chamfer, which is merely the removal of the external angle (called by the workman the arris) to any desired extent. Chamfers, however, are not confined to the removal of the external angle of the stile or rail; when boards are intended to meet together, sometimes to form panels, the edges in contact are often chamfered, forming what is called a V joint. A chamfer can be made with any plane, but in order to obtain regularity of angle and distance, special planes are often used.

When the chamfer does not extend from end to end of the piece of wood, it is called a stop chamfer; and these stops may be of various patterns, and often give a very ornamental character to the article, as may be seen in the well-known Oxford frames. In making stop chamfers, a special plane is often used, but with care the amateur can do very good work with a well-sharpened chisel. A very good plan to make stops of an

ornamental character is to make a template of wood or sheet zinc, or even a piece of cardboard cut to the worker's fancy, and used to mark the work with. Vertical mouldings of the ordinary types are often terminated by a stop, or chamfered horizontal rail; the intersection of the stop with the moulding frequently develops beautiful curves. Examples may often be seen in Gothic stone-work as well as in wood-work.

The next simple mouldings are beads. These are of varied kinds, and have divers uses. The beaded edge, which is the reduction of the square edge of a board to a semi-cylindrical contour; the "stuck" bead, generally made with a bead-plane, but it can be made by a suitable scraper. This consists of a groove called a quirk, about one-tenth of the width of the bead, while the other nine-tenths of the nominal size consist of a semi-circular outline. Bead-planes are to be had in various sizes, from $\frac{1}{8}$ in. upwards. A bead-plane having a cutter set at a certain angle, shaped to fit the figure of the plane, cannot have all parts of its edge formed in the most favourable way; the ends of the semi-circle must be formed more by scraping than by cutting the wood. Hence there is a limit to the size of bead-planes, and this will be an explanation of the difficulty found by learners in handling moulding-planes; the plane-maker has set the iron so that it is in its best average position to cut the entire moulding, and that involves the need of the plane being held at an angle often very inconvenient to the beginner. Beads are often applied to flat surfaces and margins, to break up the surface and give variety of effect.

## PADS TO OPEN AND RELEASE A FALLEN HORSE.

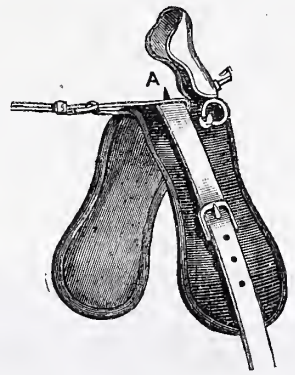
BY JOHN CHARLES KING.

"ANOTHER horse down!" This ejaculation is heard often in damp weather when horse traffic is on asphalte roadways; less frequently on wood pavement, less still on stone pitching, and rarely on macadam roads. As the system of using asphalte pays some of the interested parties well, the roadways are made of it, to the serious harm to horses, harness, and vehicles, besides stopping for a time the onflow of the road traffic.

The trouble when a horse is down is to keep him down until his harness is unbuckled, about which there is plenty of help and suggestions, and sometimes the knife is used to divide a stubborn strap that cannot be unbuckled. Even carters and coachmen are sometimes puzzled which strap or chain to undo first. A moment's glance at a horse harnessed to any vehicle will show that the traces have two attachments: one to the vehicle and one to the horse. As the horse often lies upon one trace, and has a free kicking leg over or under the other uppermost one, the unhooking is awkward to effect, and a lot of pulling and hauling is the result, with muddy clothes, caused by kneeling on the road, to do that which it is a mistake to attempt to do. At the ends of the traces attached to the horse's collar is the proper place for detachment, as it is done in an instant easily, by unbuckling the bottom hame-strap; then the hames and both traces can be lifted back along the back of the horse to the vehicle out of the way.

The next fixing is a tug on each side of the back-band in which each shaft goes. The best chaise-harness has a buckle on each side that fastens the back-band, so that either one releases this part of the harness from the horse, but the tags, being still on the shafts, have to be got off somehow; the best plan is to pull the vehicle back: this draws the shaft points out of the tug-loops. This part of the harness has been improved to facilitate rapid detachment of a fallen horse from a vehicle; and as it is simple, inexpensive, and self-fastening, and may be of service to WORK readers who are carriage users, it is given to them.

The illustration shows a hinged saddle-top to the pad, which, when unlatched and open, shows the crupper strap holding the back-band strap in its looped end; both are held by a short spike standing up at A. Now it is obvious that if the back-band buckle is undone the shafts are free to be lifted up away from the horse till checked by the pad through which the back-band slides. If the pad-top opens, as is shown, and the back-band and crupper be lifted off the spike, the whole of that part of the harness with tug-loops still on the shafts, and kicking and breeching straps still fixed to the shafts, can be lifted clear of the horse, and the horse can rise without breaking any of his harness. He will still have on his collar without harness, his pad and girth without back-band, crupper, or breeching, and his bridle, which will not have been interfered with. Replacing the harness and back-band by lowering the shafts, fastening the hame buckle and back-band buckle will be all that is needed to make the horse ready for a start again.



Pad to open and release Fallen Horse.

At a "horse down" scene on asphalte, amidst shouting, straining, and even vainly trying to unhook traces from a kicking horse, a lady, driving a gig, reined in, and, handing the reins to her groom, said: "If you will all look on I will get the horse free of his harness." All was silence: they did look on. A bystander held the horse's head; the lady unbuckled the hame-strap; the harness sprang back out of the collar "wale"; she unbuckled the crupper-strap from the pad—this was to release the breeching from the horse. "Pull back the cart now," she said. It was done, and she stepped into her gig and drove off as the horse rose free of his traces and breeching, and quiet, by the steady, quick handling of one who knew.

From this it appears that practical knowledge of their business is not to be found in all who have the care of animals, and especially of horses. This is shown far too frequently by the brutal treatment to which horses are too often subjected by their drivers who use the lash, at times without reason, and when it is in no way required. It has been well said that more is done by patting than by scratching any day, and this is pre-eminently true with reference to horses.

## SCREWING TACKLE.

BY "DAMON."

TAPS—TAP-WRENCH—SOCKETS.

IN my last paper, which appeared in Vol. III., page 343, of WORK, I endeavoured to describe a method of grooving taps so as to give them the section which is now universal among tap-makers. Before proceeding, I must make a brief digression to explain why this section has been adopted, to the exclusion of the rest. Various methods of producing the cutting faces have been followed at different times. Originally, the ordinary method was to file four flats or faces on the thread, giving four cutting faces at right angles to each other. A tap of this kind is shown in section at A, Fig. 1. This form is a very bad one, especially for tapping cast iron. The cutting angle is 135°, which is far too great—in fact, it hardly cuts at all, but acts more by squeezing the metal into the form of a thread. Cast iron crumbles to pieces under the pressure, and the resulting thread is very poor. Great exertion is required to turn a tap of this kind, and it is necessary to make the shanks extra strong, or they would be twisted off with the strain. Owing to the power used in turning them round, they are more readily broken than taps of a weaker section which cut more freely.

A great improvement on this form is the triangular one (B, Fig. 1). In this case the cutting angle is 120°. It does not, however, leave much room for the cuttings, and if much thread is left between the faces it is hard to turn. Backing off the thread a little improves this, but the clearance thus given must not be excessive, or the points will dig in and be broken off.

The half-round section (C, Fig. 1) has also been advocated. This gives a cutting angle of 90°. It cuts freely, and is said to stand well in spite of its apparently weak section. It, however, has only one cutting face, and is easily displaced from its true direction when in use, which is a great drawback.

In the fluted form having a radial face (as at D, Fig. 1), the cutting angle is also 90°. It has three cutting faces, which lessens the exertion required to turn it, and it is readily kept true in the hole being tapped. If the grooves are made as at E, Fig. 1—as is usual with some makers—the angle approximates to 90°, and the taps are easier and safer to harden. Of course, if the cutting faces are made as at F, Fig. 1, the angle is keener, but when the forward motion of the tap is reversed so as to withdraw it, the extreme points of the thread are apt to break off. However, as I have previously explained, the larger sizes of taps are often made this way, because the thread being stronger they stand better. A great deal depends, too, upon the hardening—it is so easy to burn the points of the threads when they break off at once.

Patents have also been taken out for taps having loose or, rather, detachable cutters, but this is only available for the large sizes, while the fitting is quite beyond the skill of the ordinary amateur.

It would seem, therefore, that the three flutes as usually cut give the best results, and have the fewest disadvantages. Now, to resume our tap-making. The style of grooving shown (D and E, Fig. 1) can be cut with ordinary care on taps down to $\frac{1}{4}$ in. diameter. In the case of smaller ones the operation becomes more difficult, and calls for more skill on the part of the operator than the amateur usually possesses, although

I have seen three spiral grooves cut in a ⅛ in. tap by an amateur on a double-geared milling machine, capable of driving 6 in. cutters; but this, of course, required great care and skill. However, for taps from ⅛ in. downwards, it is better not to cut grooves, but to file flats on the screw. The obtuseness of the cutting angles is not so great an objection in the small sizes. It is better in all these small taps to make the square on the shank stronger than usual, so as to avoid the risk of breaking from the torsion.

Machine taps for tapping nuts are generally made as shown in Fig. 2, so that one tap only is required to cut a full thread. From the point a portion of the tap is turned down to the bottom of the thread. This part is inserted in the hole in the nut, and acts as a guide to the tap while the thread is being formed. As the tap revolves the nut is moved forward until the tap starts cutting. At the top end of the tap a portion about equal in length to the diameter is left parallel. The rest of the body is tapered. The tap is passed right through the nut, and the thread is thus cut at one operation.

When the tap is intended to be used for cutting dies, etc., more flutes are usually put in. The flutes are cut with an angular cutter, just leaving a round at the bottom of the grooves. About nine flutes may be put in a 1 in. tap of this class. These taps are commonly called "hobs," and are used to cut worm wheels, chasers, and similar work. As space cannot be given in this paper, I will not attempt to describe the manufacture of dies and chasers now. The hob for cutting a worm wheel is made the counterpart of the worm, being the same diameter and same shape of thread. The flutes are then cut parallel to the axis of the worm. The threads are backed off a little, and the hob is hardened in the usual way.

In drilling holes for tapping, a little clearance is generally allowed in excess of the diameter of the screw at the bottom of the thread. This allowance should really be greater for wrought iron than for cast iron, but in practice the same drill is used for both. A short time ago I gave in the "Shop" columns of WORK a list of the sizes of tapping drills I use. I will, however, make out a fuller list, and, if I am permitted to do so, give it in a future paper, as it may be of use to some readers.

Although the hole intended to be tapped may be drilled quite square and true, the tap, owing to unskilful usage, may not follow the hole, and so get out of its true direction. To avoid this, steady, even pressure should be exerted on both ends of the tap-wrench while the tap is being started. Care should also be taken to watch the progress of the tap, and if the eye is not a sufficient guide, a small square should be applied in two different directions as a test.

The tap-wrench, or lever used for turning a tap round, is shown in Fig. 3. The square hole in the middle is to receive the squared part of the tap shank. The corners of the hole are generally relieved, so that the corners of the shank will not get the pull. The handles are round, and generally tapered. Their length varies according to the diameter of the tap. The wrenches are generally stamped with the diameter of the tap they fit.

The socket shown in Fig. 4 is used when some obstruction prevents the wrench being turned round. The square hole A at the one end fits the shank of the tap. The end B is made square to fit the wrench, which by the length of socket may be lifted clear of the obstruction. In fact, the socket is just like an ordinary "box-key," and answers a similar purpose.

In tapping wrought iron and steel, oil should of course be used as a lubricant, but it is not necessary for cast iron and brass.

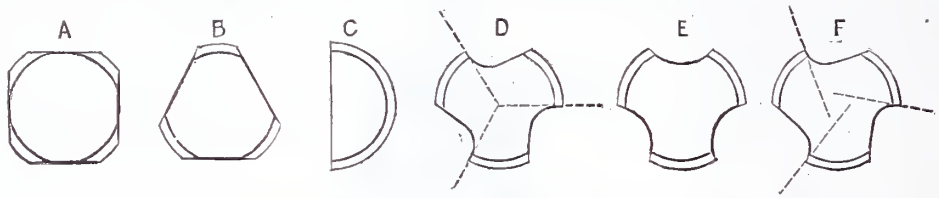


Fig 1.

Fig. 2.

Fig. 3.

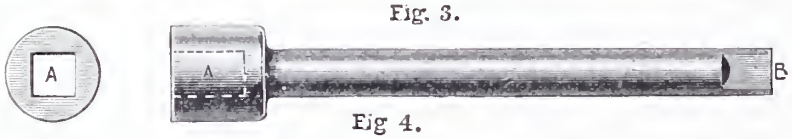

Fig 4.

Fig. 1.—Sections of Taps. Fig. 2.—Representation of Machine Tap for tapping Nuts. Fig. 3.—Tap-Wrench. Fig. 4.—Socket.

After use, taps should always be wiped clean before being put away. They should not be allowed to knock against each other, as it spoils the thread.

## PHOTOGRAPHY AS A MEANS OF HOUSEHOLD DECORATION.

BY WALTER E. WOODBURY.

THE method of mounting prints, described in the preceding paper, can also be utilised in various other ways; mounted in plush they form very handsome wall plaques. I once saw a very pretty card-table made with a number of photographic prints. Fig. 7 will give some idea of the manner in which it was constructed. A piece of deal is cut to the shape shown, and a piece of glass also; to this the photographs are mounted as described, a black paper strip being pasted in front of all the joints. A brass edging to hold the glass and wood firmly together completes the top.

Many amateurs work with a small quarter-plate or detective camera; with these photographs a very pretty chess- or draught-board can be constructed. Fig. 8 shows the idea. A piece of white cardboard is marked out into sixty-four squares of the size required, and the photographs pasted on. Thirty-two will be required to form the usual black squares. After mounting, the whole can be varnished with several coats of a good protective varnish, and the board stiffened with wood or stout boards.

A much better plan, however, is to mount the pictures in optical contact, as already explained, to a sheet of thick plate glass. The position of the pictures is obtained by laying the glass on a sheet of paper, previously ruled, with the correct-sized squares. A piece of white paper is then mounted on the back, and the whole attached to a wooden frame or table-top. The glass thus forms the top of the table, and the constant moving of the chessmen cannot injure the views.

This method of mounting prints to glass may often be employed for improving unsightly objects. To give some idea of what I mean, I will give a case that recently attracted my attention. A friend had a rather handsome mirror standing over his dining-room mantelshelf, but by some accident, or by the effect of dampness, the silvering of the glass in a portion of the centre had completely left it in places, forming a very unsightly spectacle. My friend, however, removed the mirror from the wall and carefully scraped away a portion of the silver, leaving an opening about 8 in. by 14 in. All the affected parts were thus removed, and he then backed the opening up with a carefully selected artistic photograph gelatinised and squeezed on. The effect surpassed his expectations. The unsightly portions were removed, and the presence of the picture much improved the appearance of the mirror.

We now come to a very important process, *i.e.*, the transferrotype. With this, photographs can be transferred to almost any substance. The Eastman Company and their agents supply a transferrotype paper which they manufacture. This is briefly a paper coated over with a soluble gelatine, and afterwards with an insoluble gelatine sensitive emulsion. With this paper, prints are first made as with bromide paper; they are then transferred to any substance by squeezing them into contact and laying in warm water, which dissolves the soluble gelatine film and releases the paper support, leaving the insoluble gelatine image upon the new support.

I, however, much prefer a transferrotype collodion process, with which I have had much success. Briefly described, this process consists in the preparation of a collodio-citro-chloride emulsion, which is coated over paper previously treated with gum arabic. The sensitive paper thus prepared is printed

in the ordinary manner. To remove the collodion film from the temporary support, after the image is printed on it, it is only necessary to immerse the print in cold water. The gum substratum is then dissolved away, leaving the film attached to any suitable material or object.

The first thing to be considered is the preparation of the collodion emulsion. For this we first of all require a plain collodion. This can best be prepared by mixing equal parts of ether and alcohol, and adding from two to three per cent. of English pyroxyline. I find that the best proportions of the latter are two per cent. during the summer, and three per cent during the winter months. A thin collodion will always be found preferable to work with—it gives an evener film; and if it be afterwards found to lack density, it is not a very difficult matter to coat the paper twice or to allow the emulsion to remain a little longer on the paper before pouring off the superfluous fluid. It is a well-known fact that collodion likewise improves with age. An old collodion should always be preferred to one freshly made, as it works clearer and cleaner. It is, therefore, advisable to prepare the collodion some little time before it is required for use, and

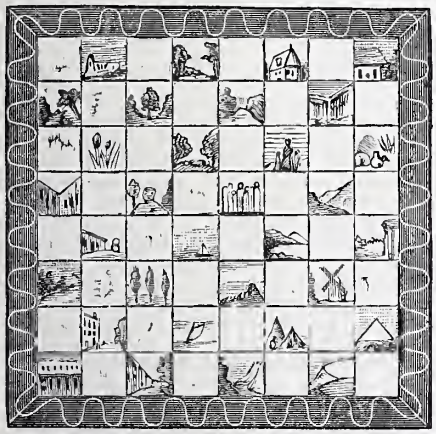

Fig. 8.—Chess- or Draught-Board.

to carefully decant it into another bottle without disturbing the sediment at the bottom of the bottle. The addition of a half per cent. of castor oil gives a wonderful finish to the glaze of the picture, and also improves the tone.

Into a glass measure capable of holding about 100 c.c.,* place about 13 grammes of silver nitrate, and 15 c.c. of water. Thoroughly dissolve the silver, and add 50 c.c. of alcohol—the addition to be made very slowly—rapidly stirring the solution the while. Into another small measuring glass dissolve 3 grammes of citric acid in 50 c.c. of alcohol, and in another 3 grammes of chloride of strontium are dissolved in 50 c.c. of alcohol.

We now have four vessels, one containing the collodion, one the citric acid solution, another the silver solution, and one with the strontium chloride. When all the ingredients have been dissolved, the citric acid and the strontium solution are added together, stirred up well, and placed in another vessel containing 100 c.c. of the plain collodion. We have now two solutions, *i.e.*, the collodion containing the chlorine and the acid, and the silver solution. We must now remove to the dark-room, or to a room lighted by gas or yellow light. The two solutions are now added together by gently pouring the silver solution into the other. The whole must be rapidly stirred and shaken up. As soon as the two solutions are added together, the sensitive emulsion is formed, the silver combining with the chloride to form sensitive silver chloride held in suspension by the collodion. The next operation is to filter the collodion; this can be accomplished by means of a tuft of cotton-wool placed in a glass funnel. It is then ready for use.

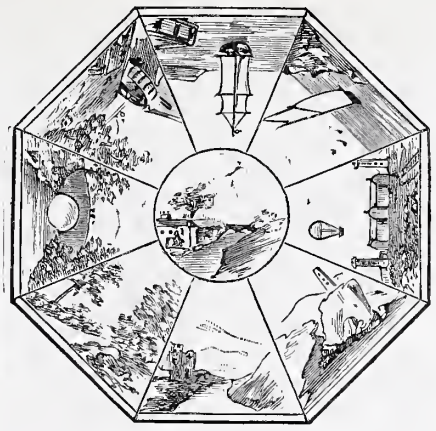

Fig. 7.—Octagonal Card-Table.

The paper to be used can be obtained at any large stationer's. It is best gummed paper doubly coated with gum arabic. A sheet of this paper is laid on to a sheet of glass and coated with the collodion. Those who have not had much experience in collodion work had better turn up the edges of the paper for about $\frac{1}{16}$ in. all round to prevent the collodion overflowing. A little of the collodion is poured on to the upper right-hand corner of the paper and worked all round till it covers the sheet. The superfluous collodion is then poured off, and the paper hung up to dry. When quite dry it is ready for printing upon. It is cut up to size, placed in the printing frame behind the negative, and printed out in the ordinary manner. If required to be transferred to glass for transparencies, it will be necessary to print very darkly indeed.

The surface to which it must be transferred is now thoroughly cleaned and treated with a ten per cent. solution of gelatine, either by coating or by means of a brush. The print is then trimmed to the size required and squeezed into close contact, the gelatine, while damp, causing it to adhere very firmly. The next process is to tone and fix. The print attached to its support is laid in cold water, when the gum layer dissolves, and the paper will float away. It is then treated with an ordinary gold-toning bath, and afterwards fixed in hypo. I prefer, however, to do these two operations with one solution—a combined toning and fixing bath. This is made up as follows:—Solution No. 1: distilled water, 36 ozs.; sodium hyposulphite, 8 ozs.; sulpho-cyanide of ammonium, 1 oz.; acetate of soda, 7 drachms. Add to this—water, 6 drachms; sodium chloride, 2 drachms; silver nitrate, $1\frac{1}{2}$ drachms. After this mixture has been allowed to stand for about twenty-four hours small flakes of insoluble compounds will be seen. These must be removed by a double filtration. While this is proceeding make up solution No. 2: distilled water, $3\frac{1}{2}$ ozs.; gold chloride, 15 grains; ammonium chloride, 1 drachm. Add solution 2 to solution 1, and, after well shaking and allowing impurities to settle, the bath is

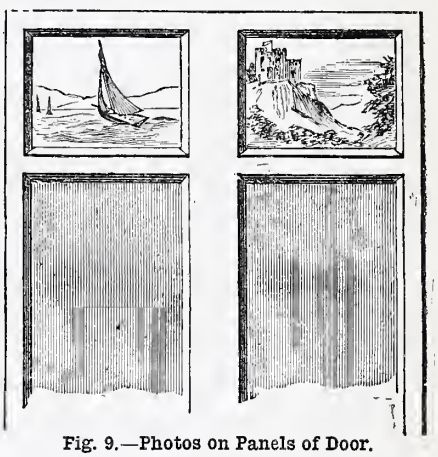

Fig. 9.—Photos on Panels of Door.

ready for use. After toning and fixing, the prints are well washed in a running stream of water.

It will often happen that the object to which it is required to transfer the photographic image is not of a nature to stand this treatment with the various solutions. In this case the print is first immersed in water, when the collodion film containing the image will leave the paper. By very careful manipulation the loose film can be toned, fixed, and washed, and afterwards transferred to the object.

With this power of transferring the pictures to any substance, the number of pretty objects that can be made is at once apparent — card and cigar-ash trays, paper weights, etc. etc.; and the number of ornaments, vases, plates, etc., that can be improved by a well chosen photograph is unlimited.

The next process we have to describe is that known as the Diazotype or primuline process of printing

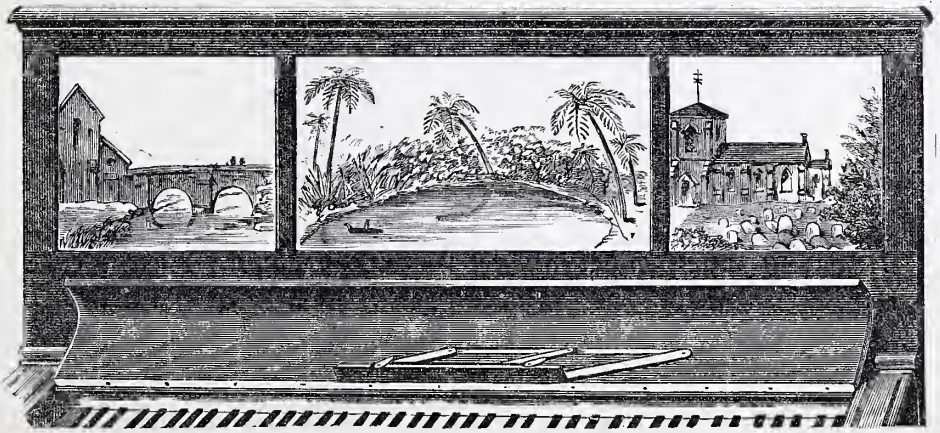

Fig. 10.—Top of Pianoforte decorated with Photographs.

* Those unaccustomed to the metric system of weights should read the figures as "parts."

upon silks, wool, cotton-stuffs, by which very pretty ornaments can be made. Photographs can be reproduced in a variety of beautiful colours upon the silk, and then handed over to the ladies to be made up into some fancy article.

All the materials for working this beautiful process can be obtained from Messrs. Green, Cross, & Bevan, who are the inventors and patentees of the process. In this process the material is first dyed with a hot solution of primuline, to which a small quantity of common salt has been added. About 15 to 30 grains of primuline are added to about a gallon of hot water. The addition of the common salt increases the affinity of the colour, and hastens the operation. For silk and wool the water must be nearly boiling, and twice the quantity of primuline used. In this solution the fabric acquires a primrose-yellow colour. It is then wrung out and well washed in cold water. If necessary, the material can be dried and kept until required for use.

The next operation is to diazotise by immersion for about half a minute for cotton, and two or three minutes for silk and wool, in a cold solution of sodium nitrite, ½ per cent., sharply acidified with hydrochloric or sulphuric acid. The material is now sensitive to light, and is well washed in cold water, dried, and stretched out on a level white surface and exposed to light beneath a photographic positive. The exposure varies, of course, with the actinicity of the light. In sunlight about half a minute will be required, while in dull weather half-an-hour's exposure may be necessary. The image is faintly visible, orange-coloured on a light yellow ground. The next process is to render the image visible by development. This is done with a weak solution (about ¼ per cent.) of a suitable phenol or amine. The following have been found to give very good results, each developing the image in a different colour :—

*For red.*—An alkaline solution of β-naphthol.

*For maroon.*—An alkaline solution of β-naphthol-disulphuric acid.

*For yellow.*—An alkaline solution of phenol.

*For orange.*—An alkaline solution of resorcin.

*For brown.*—A slightly alkaline solution of pyrogallol, or a solution of phenylenediamine hydrochloride.

*For purple.*—A solution of α-naphthylamine-hydrochloride.

*For blue.*—A slightly acid solution of amido-β-naphthol-β-sulphonate of sodium (eikonogen).

If the design is required to be produced in two or more colours, the respective developers, suitably thickened with starch, must be applied locally with a brush.

After development is completed the material is well washed in cold water, and should then be dried and ironed. If the purple or blue developers are to be used, the material should be finally washed in a very weak solution of tartaric acid.

Instead of printing from a photographic picture, images may be made from leaves, flowers, ferns, insects, or other designs upon paper.

I will conclude this article with a description of the dusting-on or powder process. With this, images in all colours can be produced upon glass, wood, paper, etc. The method is as follows. The substance which is to form the support is coated over with the following solution :—Gum arabic, 30 grains ; white loaf sugar, 30 grains ; ammonium bichromate, 20 grains ; distilled water, 1 oz. After drying, this is placed under a photographic transparency. The exposure varies from five to twenty minutes. An actinometer should be used as in carbon printing. The image is then developed by dusting over powdered graphite or other coloured powders which adhere to those parts of the gelatine film unexposed to the light. It is then coated with collodion, well washed, and varnished. If a dark-coloured ground, and a light-coloured powder such as ivory dust, barium sulphate, silver dust, etc., be used, the image can be made from a photographic negative. Very effective pictures may be thus made ; for instance, if done upon wood, and inserted in the panel of a door or cupboard, they improve its appearance wonderfully (see Fig. 8).

I have recently had suggested to me, by a young lady, the idea of improving the appearance of the pianoforte top by the insertion of artistic photographs (see Fig. 10).

I am well aware that the subject I have taken up is so inexhaustive that I have only been able to give a small percentage of the number of ornamental articles, but I think I have been able to at least show how useful photography could be made to become as a means of household decoration.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### III.—"THE ART AND CRAFT OF CABINET-MAKING."

WITHIN the last ten or fifteen years marked advances have been made in what may be called "practical literature," and at the present time there are but few trades that have not as a *vade mecum* a text-book treating of the means, modes, and methods. With reference to furniture making, the above-named manual has only just made its appearance, but I may safely say that among the various technical books that have been recently published by Messrs. Whitaker & Co., there is not one, perhaps, that is possessed of such value, or is likely to command such a steady and continuous sale as a "stock book." as "The Art and Craft of Cabinet-Making," which purports to be, and really is, "a practical handbook to the construction of cabinet furniture, the use of tools, formation of joints, hints on designing and setting out work, veneering, etc., together with a review of the development of furniture." My reason for speaking in such positive terms as to its worth is that it is written by Mr. David Denning, whose name and intimate acquaintance with the subjects on which he writes are well known to every reader of WORK. Its purpose, aim, and scope may, perhaps, be best set forth and explained by an extract from the preface, which shows in plain and unequivocal terms that, in writing this work—and I know of no one who is better capable of doing it, either by reason of his power of imparting information by pen and pencil, or through his intimate knowledge of every branch of cabinet-making—the intention of its author has been, and is, "to supply amateurs and young professional cabinet-makers with a reliable guide to the construction of cabinet furniture. No attempt has been made to teach the thoroughly experienced artisan, and no new fads are advocated, either in style or processes. The ordinary reliable methods of the workshop, and nothing more, are explained, and on this account the book will, no doubt, be of greater use to those for whom it is intended than if new theories of 'construction as it ought to be,' according to many of those who presume to teach the skilled mechanic, had been advocated."

Having thus given, in Mr. Denning's own words, his apology for the existence and appearance of the volume now under consideration, let me endeavour to show the readers of WORK not *how* the writer has handled his subject, for that goes without saying, as the phrase runs, but in what way he has commenced and gone through his subject, which is one that covers a wide field and demands, in order to write on it with effect, a general knowledge which but few possess. The book consists of twenty chapters or component parts in all, and is well illustrated with two hundred and nineteen engravings of tools, appliances used in cabinet-making, diagrams explanatory of joints, parts of pieces of furniture, and processes, and sketches of many articles of furniture, useful and ornamental, most of which bear evident marks of originality—or, in other words, of having been supplied by Mr. Denning himself. Reverting to the subject-matter of the work itself, and its general arrangement, the writer first takes the opportunity to show the difference, not always clearly understood, between joinery and cabinet-making, and to show what is the special and acknowledged work of the cabinet-maker. From this he proceeds to a review of the development of furniture, giving a sketch of its progress from the Tudor period to the present day, and showing that good modern work is much to be preferred to that of bygone times, however much it may be the fashion to cry it up. After a brief chapter devoted to an account of the woods chiefly used in making furniture, Mr. Denning comes to an important section of his subject, in which he dwells at length on glue and its preparation, nails with which screws—or screw-nails, as they are sometimes called—and other fasteners are considered ; tools used in cabinet-making, wooden appliances that may be, and indeed are, for the most part, made by the user, and grinding and sharpening tools, with general directions. The six chapters devoted to these matters may be regarded as forming the second section or part of Mr. Denning's book.

In the third part he touches on the joints used in cabinet-making, various decorative and minor structural details in furniture, and the construction of parts, such as drawers, doors, cornices, plinths, etc. Following these in due sequence, he tells the reader all that is necessary to know about many indispensable adjuncts to modern furniture, such as glass, which is now very extensively used, and cabinet brass work, and he sandwiches these—if I may be permitted to use the term—with a chapter on drawing and designing and another on the process known as veneering, or putting, as may be said, a good face on a material of inferior value. The fifth and last portion is devoted entirely to the consideration of construction, and the four chapters of which it is composed touch respectively on tables, bedroom furniture, library and office furniture, and sideboards and cabinets. Now this is all desirable and necessary, but I am compelled to say that if there is not a "missing link," there is certainly a missing chapter, in which the construction of chairs and couches should have met with respectful comment and treatment ; and when "The Art and Craft of Cabinet-Making" reaches a second edition, as I trust it very soon will, it may be enlarged and improved by the addition or interpolation of such a chapter. I know that in taking a bird's-eye view of any wide and comprehensive subject it is a matter of the utmost difficulty to think of everything, and that something or other that should have appeared has been accidentally crowded out ; but this is the only "one thing wanting" that I have been able to detect in this otherwise complete, carefully considered, and well-written book.

THE EDITOR.

## SHOP:

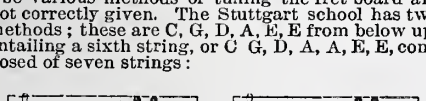
### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Hints on the Stringing of the Zither.**—T. G. M. (*Camberwell*) writes:—"Chancing to see No. 139, p. 550, of your valuable publication, Work, I found in it an article concerning the zither, as to its setting and tuning, with general remarks appended; but it contains inaccuracies and misleading information, to which I feel constrained to call your attention. The zither is not an easy instrument, and this is the true reason why the majority of lovers of the same fail to attain to any kind of perfection in their play, and also why so many who have not been debarred from starting the acquisition of zither-playing finally break down and give it up altogether. I am much afraid that inferior teachers are responsible for this state of things. I was fortunate myself in obtaining in London a perfectly practical instructor, who never digressed into irresponsible statements, and who thought more of his zither and pupil than of the 'main chance.' Let me first correct the following: 'Schlacht' zitber should be 'Schlag' zither, because it is struck in contradistinction to the 'Streich' zither, which is the 'bow' zitber, or Alpine violin. The Elegie, or alto zitber, tuned to E one-fourth below the outer, or A, string (which, in effect, is one octave below the fifth above the same A string), is, *par excellence*, the correct instrument for accompaniments to the voice, and also plays sentimental solos more feelingly, having a much sounder tone and longer vibration. The instrument which, however, is in general use amongst players of even mean capacity is the so-called 'Concert' zither. The 'Prim' zither is used by the peasantry of the Tyrol, when they have one at all, on account of its cheapness and handiness, and being well suited for the simple airs and dance music affected by them. The remark made that the zither can be taught in one week is ridiculous; and the statement that 'all bands' play it in the Tyrol is false. I travelled in the Tyrol two summers ago, and in the Bavarian Highlands, and made searching inquiry as to players, and always met with the same reply, 'There is only So-and-so near here;' and to the query as to what kind of music was played, the invariable answer was, 'You cannot get anybody in the country to play aught save *Ländlers* (country dances) and kindred music; they do not even rise to marches and superior dance music.' It is in the towns of Germany that the zither is cradled and made much of. On no account let anyone buy metal strings, except for the fret-board. No one uses them, all that has been said to the contrary notwithstanding. The great tension of this class of string ruins the grip of the tuning pegs, and so ruins the instrument. Their tone is harsh and clanging, and turns a sympathetic medium of music into a 'tin pot.' Metal strings 'hold up' well, but this is their only recommendation. The various methods of tuning the fret-board are not correctly given. The Stuttgart school has two methods; these are C, G, D, A, E, E from below up, entailing a sixth string, or C G, D, A, A, E, E, composed of seven strings:



The method given as the Viennese is really the Munich method, the Viennese being C, G, G, D, A, which, to be correct, must have the G between the G and D tuned one octave above the other. The Munich method is the only correct one harmonically, and is C, G, D, A, A, the two A's being tuned alike, the others being each one-fifth above one another. All the other strings of the zither are tuned in fifths, and as stated. The information given as to what there is to learn on the accompaniment and bass strings is not true; the statement being that it is only necessary to learn the position of one major chord, as all others are the same, there being nothing more to learn. One moment's consideration will show the fallacy of this. How about minor chords, augmented chords, diminished ditto, as well as incomplete progressions? Then, how about broken harmony and the various mechanical and harmonic methods not mentioned? It is due to such random statements that a beautiful instrument is depreciated by the public, and it is put down as only capable of playing 'Tum, tum, tum' music. Let me impress upon your readers that the zither well repays learning, because it is capable of such infinite variety; it is, indeed, on this account that old and experienced players are always studying—there is ever something new. To form some opinion of zither-playing, do not go to listen to 'Ländlers et hoc genus omne,' but take every opportunity of hearing good music—as solos, duets, trios, or quartettes. Ensemble or club pieces are, as a rule, too much of the 'Thrum, thrum' pattern, and not good music. As a parting word, I can also say, 'Be not afraid'; but say it as encouragement to persevere, and overcome the various obstacles lying before the student. His reward, if he has any music in his constitution, will be ample, and he will soon attain to some satisfaction."—["It is hardly kind of Dr. M. to 'slate' me so unmercifully, especially as I am a member of his own profession—which, however, is notoriously one in which 'dog' is addicted to a canine diet. Now, let us analyse the 'misleading information,' the 'inaccuracies,' and the 'irresponsible statements' contained in the article in question. The doctor will not allow that the zither is an easy instrument, in spite of my solemn assurance that I can teach, and have repeatedly taught, it in the space of a few weeks. Well, all I can say is that in the case of our critic it may, indeed, have been difficult of acquirement; while the general tone of his letter goes to prove that he would be rather sorry than otherwise to see the zither popularised—wants, in fact, to 'keep it select,' as it is, up to the present time, essentially an aristocratic instrument in this country. Nevertheless, braving the scorn and contumely of the doctor, I venture again to assert most emphatically that the zither is not only easy, but the easiest of all stringed instruments of its type. In proof that I did not at all exaggerate when I affirmed that I could enable anyone who cared to play within a very limited period, I may adduce the case of another doctor here, who, six weeks or so ago, had never touched a zither, but who is now able to play fairly well several airs, including some which embrace the very modes of accompaniment which Dr. M. says cannot be acquired by learning one major chord. That this gentleman has had no tuition other than from me, Dr. M. can easily satisfy himself, as I shall be very pleased to forward his name and address—I know Dr. M. has mine. It is ridiculous to suppose that the article assailed was ever intended as a complete compendium of the zither; nor was it intended for *virtuosi*, but for such as were open to accept simple instructions or hints at the hands of one who was perfectly competent to impart such information, and also perfectly disinterested in offering it. As to the 'inferior teachers' upon whom the learned licentiate has sat so unmercifully (and I am, by implication, included in the category), I am afraid I can only speak for myself. But in all my experience as an inferior teacher, I never yet knew of a case of relapse when once the study of the zither had been seriously undertaken; my innate inferiority, no doubt, prevented such instances from cropping up. Certainly, I was at a distinct disadvantage in every way—my practice as a teacher lying in an obscure Hampshire village called Bournemouth, of which the doctor may possibly have heard, and which, we all know, is peopled by Boors. Unkind, oh doctor! to cavil at the teacher's eye to the 'main chance.' Why, man, it was my only inducement to teach at all; yet I do not class myself as inferior to anyone in love of the zither, or as insensible to its capabilities. I am willing to believe that you are an infinitely better performer on it than I am, or than I am ever likely to be; but you surely might let experience go for something, even if only that of an 'inferior teacher. As I am always willing to admit it when in the wrong, I cry 'Peccavi' *re* the word 'Schlacht.' I simply perpetuated another man's error, as I am no German scholar; but surely no mortal in his senses could ever confound the zither proper with the Streich zither, which is an instrument of the viol family? Dr. M. is also good enough to tell us that the élegie zither is the best as an accompaniment to the voice and for slow *tempi*, which is perfectly accurate; but not so his assertion as to the concert zither being the one in most general use. As a matter of fact, the concert zither is tuned in 'G,' the prim, or ordinary, zither being in 'A;' while the élegie is pitched in 'F,' and the bass zither in 'E.' With the latter the good doctor is presumably unacquainted, or he would certainly have mentioned it in his very comprehensive letter. He also asserts that the prim zither is used by the very 'inferior' zitherists of the Tyrol, as being 'cheaper' and 'handier' than his favourite instrument — the concert zither. Now, in some German lists I have seen the two priced alike, while in an English one, which lies before me as I write, I notice that prim zithers are quoted as kept in stock up to ten guineas, and that the limit for concert zithers is £4 10s.—conclusive proof that the doctor's argument is *right*, and that the prim is invariably the 'cheaper' instrument. As to its being the 'handiest,' I don't know where it comes in, if by the term the doctor means portability, etc. This very captious gentleman also takes exception to my remark as to the universality of the zither among the peasants of the Tyrol. Now, in 'Grove's Dictionary of Music and Musicians'—a reliable and standard work, I think—under the article 'Zither' will be found the following: '. . . . as constructed about half a century back, when it became a favourite among the peasantry of the Styrian and Bavarian Alps.' I have not enjoyed the advantage of bearding the zither in its native lair—so to speak—as has the doctor; but I think it is extremely possible that the natives were shy of performing before him, as his fame must inevitably have preceded him; and, indeed, if they had any suspicion of the contempt in which he holds their beautiful 'Ländlers,' it is not to be wondered at. Now, whether these poor unfortunate zitherspielers have degenerated or not, it is a significant fact that Petzmeyer, the father of the zither in its present form (as well as Gusicow, Picco, and other world-famed players), was a perfectly self-taught player, and was not only ignorant of even the rudiments of musical science, but was also otherwise illiterate; yet he was appointed Kammer—*virtuoso* to the king—which proves that it does not follow that a man must be acquainted with music at all to be a good performer. That the *dilettanti* consider this the worst of heresy I am well aware. The doctor's moan because he could not find exponents of a class of music to which the Tyrolese were not accustomed is about as ludicrous as if one were to quarrel with a Scotch piper because he could not render an oratorio! In the towns of Germany, the doctor says, the zither has been developed. Quite so; as, even in benighted Germany, the talent flocks to the bricks and mortar. But Munich—which he gives as the seat of a distinct school—has no performer of international fame, whereas Vienna has several. There are many obsolete or little used methods of stringing besides the ones he cites, and really, whether the one I gave was Munich or Vienna, is a matter of very little practical importance. Now, so far I have followed the doctor with great interest, if not always in accord with him; but when he assails the metal strings in cold blood, it is too bad. They are infinitely superior in all respects to those of silk and gut. In the hands of an 'inferior teacher' or a player 'of mean capacity,' the former might, perhaps, be found harsh and clanging; but for great delicacy of touch, and an infinitely greater resiliency, commend me to the metal strings. It is sheer nonsense to talk of their destroying the grip of the pegs. Look inside a piano. Furthermore, they are very accurately balanced as to tension, whereas with silk and gut there are scarcely two strings alike in this respect. Which, then, is likeliest to conduce to a delicate and sympathetic touch? It is not considered gentlemanly in this town to give anyone the lie direct, which is what Dr. M. has done when he says that my remarks on the accompaniment are 'not true;' he should have added, 'in my opinion' or 'in my experience.' Our friend has probably acquired the zither, 'through much tribulation,' in the orthodox manner, and cannot believe that he has really wasted much valuable time. But, be that as it may, I hereby reassert all what I have said on the subject of the accompaniment. Minor chords, etc., I must venture to submit, do not come within the scope of elementary instruction; but all the graces enumerated by the doctor are to be accomplished when the pupil is once familiar with the positions of the strings, and this latter may easily be acquired by practising the major chords, only one of which need be taken until the stretch, etc., is mastered. Having thus vindicated the truth of most, if not all, of my 'random statements,' I may add that our English players have done nothing for the popularisation of the zither, and for this reason: each appears to be actuated by the same carping spirit which is so manifest in every line of the doctor's letter, and most so-called zither clubs are—well, 'select assemblies'—bem! We are warned not to set strong spiritual food before the catechumens, and the same is true with regard to the intending learner of the zither; so let every reader of Work peg away by the light of the few hints embodied in the article attacked, and I will undertake that there need be neither lapses nor failures. *Vale, Doctor carissime!*"—An Old Teacher.]

**Ancient and Curious Watches.**—F. C. (*Nunhead*) writes:—"I have recently had an opportunity of examining a curious watch in the possession of a well-known alderman of a sontbern town. This watch is three hundred years old, and is contained in an oval or egg-shaped case about 2¼ in. long by 1¼ in. wide. The front of the case is missing, but the remaining part is about ¾ in. thick. Over the dial is one hand only, to mark hours (like the clock on Westminster Abbey), and the watch is so constructed that this hand can be set to time, which is not the case in all similar watches. The movement is English verge, and the only defect in the watch at present is that the teeth of the 'contrate' or crown wheel are bent. Between the spring barrel and the fusee a piece of catgut supplies the place occupied in modern watches by a flat-link chain. The same gentleman owns another watch, the ball-mark in which is one hundred and twenty-eight years old. It is enclosed in a tortoise-shell and gold case, and has a verge movement. At the present time this watch runs with a variation in time of less than two minutes per diem. While speaking of watches, I may mention a curious repair effected by a Japanese workman. An English gentleman travelling in Japan found that the main-spring of his watch had snapped, and sent it to a native artisan. The watch was returned to him apparently in perfect condition, and its performance was satisfactory until he reached a damp district. On examination, it was found that the new main-spring was made of thin bamboo."

**Fairy Bell Pegs (or Pins).**—G. H. M. (*Bristol*) writes:—"Noticing a reply in 'Shop' offering to supply above at 1s. per dozen, it struck me as being a somewhat exorbitant charge, in proof of which I may say I shall be pleased to supply either of the enclosed three sizes at 6d. per dozen, postage 2d. extra, or for not less than three dozen, post free;

and wire at 4d. per ring (see 'Sale' column)."—[These pins are all that could be desired.—ED.]

**Xylonite and Fret Saws.**—H. B. (*Leeds*) writes that "he supplies xylonite in small quantities in its best forms—viz., ivory, ebony, coral, and tortoiseshell; also a new 'Lightning' fret saw' (see advertisement)."—[The samples sent are certainly to be commended.—ED.]

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Boot and Shoe Repairing.**—NOVICE.—The articles on "Boot and Shoe Making and Repairing" appeared in WORK, Nos. 112, 117, 122, 126, 130, and 137.

**Self-acting Fountain for Garden.**—A. L. (*No Address*).—The principle upon which the fountain works, as described in No. 69 of WORK, is undoubtedly the best for your purpose. If you read the article carefully in connection with the sketch now given, you will see the necessary alteration which will have to be made to make it an effective and convenient apparatus. The sketch will then need little explanation—the question of size is one which you must decide for yourself—but as the vessels are out of sight, and therefore cannot look clumsy, I would advise you to have them sufficiently large to play a small jet for. say, two to three hours

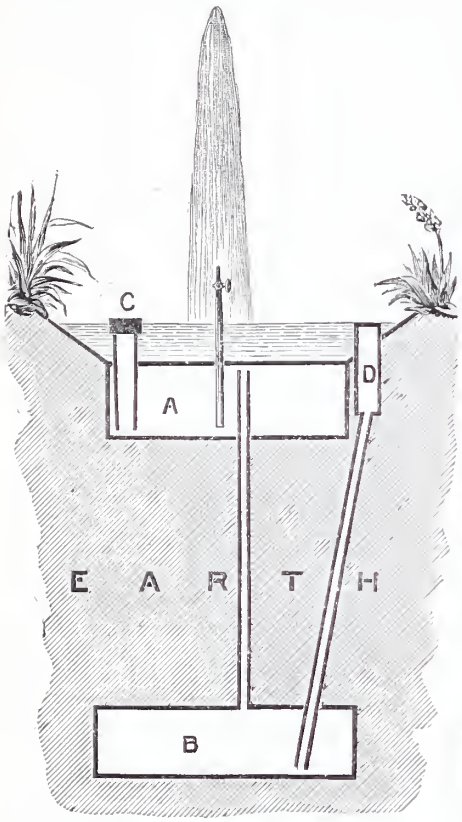


Diagram showing Buried Self-acting Fountain for Garden.

—thus: top vessel, A, 20 in. × 20 in. × 4 in. deep; vessel B, 21 in. × 21 in. × 4 in. deep; and as in the open air a feeble jet is disturbed by a very light breeze, it would be well to have a considerable force behind the jet. The latter itself need be no larger in thickness, but driven out with greater force, and hence—being much stiffer and better able to bear the wind—this force can be obtained to any extent by *increasing the distance between* the vessels A and B; the size and shape of the vessels have nothing to do with it. I would recommend not less than a clear 4 ft. between the vessels. The earth would have to be excavated to accommodate these dimensions, and when the fountain is made up, *thoroughly tested* for leakage, and filled up, a zinc cone somewhat like a milk-pan should be soldered to top of vessel to form basin, and the edge neatly built up with rustic rock-work. To use the fountain, pour water into the basin until no more will run down the pump-hole, D, and the basin is also conveniently full; then, to make it play, unscrew the plug, C, and work the pump up and down, when water from B will be sucked up into the basin, and drawn down the plug-hole, C, into A. When B becomes empty, air will come up instead of water, accompanied by a gurgling sound; then restore the plug, and *afterwards* cease from pumping, when the water will instantly rise from the jet and continue playing until A becomes empty. It is essential that the vessels and joints should be air-tight, and they should be tested to a higher pressure than they will be used at. With regard to price, this will vary very much in localities. As you do not give any address, I am unable to surmise. —C. M. W.

**Cyclometer.**—W. W. (*Stamford Hill*).—I am unacquainted with the interior mechanism of the cyclometer. It is not a job for a novice, however, but for a practical optician. I am sorry I cannot supply a drawing, as I have not the article by me. It would be cheaper and better to buy one of the makers or cycle dealers. Consult WORK advertisements.—A. S. P.

**Fitment for Small Harmonium.**—A COUNTRY CABINET-MAKER.—It would be beyond the scope and purpose of WORK to give instructions as to how to play any particular instrument, the construction of which is set out in the journal.

**Pneumatic Tires.**—A. S. (*Glasgow*).—The repair of these tires requires initiation, and no novice should attempt it without first seeing it practically done, and repairers are not fond of showing the process to everyone.—A. S. P.

**Clay Modelling.**—M. J. C. (*High Wycombe*).—The articles on "Clay Modelling" appeared in WORK, Nos. 56, 60, 64, 68, 71, 74, 77, 83, 88, 93, and 98.

**Suggestions for WORK.**—W. N. (*Homerton*).—Thanks for your suggestions. I am always glad to have these from any reader. Your efforts to make WORK better known among your friends, and your introduction of it into your school, will no doubt be productive of good all round. As to tools, you will see that B. A. Baxter is already dealing with carpentering tools, and no doubt he will treat the subject exhaustively. Your required information as to enamelling a coal vase only awaits its turn in "Shop."—ED.

**Collodion Wet Plate Process.**—AMATEUR.—Your best plan would be to purchase an elementary shilling handbook on photography, which will give you more detailed information than it is possible to do in the limited space of these columns. All the necessary materials may be purchased of almost any photographic material dealer, such as Fallowfield; or Adams, Charing Cross Road, W.C., will supply you.—D.

**Enamel.**—J. R. G. (*London, S.E.*).—You cannot do better than use the Foochow or Aspinall enamel advertised in WORK.

**Architecture.**—WOULD-BE.—Before wasting any money in buying books, I should advise you to write to the Secretary of the Royal Institute of British Architects, 9, Conduit Street, Hanover Square, London, W.; or to the Secretary of the Glasgow Institute of Architects, 115, St. Vincent Street, Glasgow, plainly stating your case, and asking their advice.—E. D.

**Bell Telephone.**—N. D. (*Sheffield*).—I am pleased to learn that you have succeeded in making your telephone so well from my instructions given in WORK. It shows that my labour has not been in vain. The further information which you require regarding transmitters and switch-board has been written out fully with drawings, and is in the hands of the Editor. Perhaps, if you and others use some persuasion, he will be induced to publish the same at an early date.—W. D.

**Sawing.**—A STUDENT.—Sawing against the grain, especially in curly or knotty wood, is, of course, more difficult than sawing along the grain of a straight and regularly grained piece of timber. From A STUDENT'S letter I should think his saw is not in good order, for sometimes "the saw seems to refuse to move altogether." Is this so? For a correct and complete answer to this, read J. H.'s article in WORK, Vol. I., p. 161, dated June 1, 1889, then examine the saw carefully in the light of the knowledge gained.—B. A. B.

**Safety Bicycle.**—ERIC.—Your correspondent is quite right in his remarks in reference to the adjustment of pedal-shaft, and I am not wrong. It is this way: As to wheels, the hubs revolve round a fixed axle. These hubs always have the spindles made with a right-hand screw, and if made with a fast and loose cone, the loose cone is always on the *left* side as described, and as ERIC says. With regard to a pedal-shaft, the hub, so to speak, is a fixture, and the shaft revolves. If the pedal spindle has a fast and loose cone—the fast cone being, as it always is, next the chain wheel, and the shaft or spindle a *right*-hand screw—then the chain wheel would be on the *left* side, and the loose cone on the *right*—just the reverse of the wheel spindle; the operation of driving would then wind a loose cone *outwards*. But nearly every safety that I have handled in the last two years for repairs had the pedal-shaft made with a *left*-hand screw, and the loose cone, consequently, on the *left* side, and it was one of these brackets I had by me when I wrote the description, which is correct when applied to the *left*-hand thread, as it was meant to be. Your correspondent, who evidently knows what he is talking about, will see that my description applies, as he mentions, to a left-hand, threaded shaft, which fact I ought to have mentioned when writing the description.—A. S. P.

**How to Make a Hot-Air Engine.**—S. T. (*Oughtibridge*).—You ask how to make one, but without saying what size. I don't know whether you mean a model or a large one. I think an amateur could not well do more than a model, because the cylinder of a hot-air engine is necessarily large, and the heater big and bulky. What could you do towards making a hot pot and displacer 12 in. or 14 in. diameter? You might make the patterns if you have a large lathe, but most of the work is done in the foundry. Then the cylinder requires a power-lathe to bore it, and so does the fly-wheel and crank; then what remains for you to do? You might make a model, and before this appears you will have seen a drawing and description of Mr. Seal's simple little engine, sent in answer to another inquiry, which plan you might follow, taking a pipe of some kind as the foundation, the furnace below the heater in the middle, and carry the crank-shaft above. I would make the cubic space moved through by the working piston one-quarter that moved through by the displacer, and if you have a 5 in. working cylinder, you might drive a sewing-machine, fret-saw, or 3½ in. lathe.—F. A. M.

**Cabinet Making.**—SIRINO.—I cannot call to mind a book such as you require. Messrs. Cassell and Co. publish "Drawing for Cabinet Makers" (3s. Read my reply in "Shop," No. 140, Vol. III., headed "Advice to Draughtsmen;" you may find some books therein mentioned of service, if you are not already acquainted with them.—J. S.

**Cheval Screen.**—N. M. (*Norwich*) may, it is hoped, find in the annexed sketch the hints he requires for making up his tapestry as a cheval screen. The uprights and cross-pieces should be about 1½ in. square. The fret (Fig. 2) must also be cut from stuff of the same thickness. The pieces A and B (Fig 1) should be of ½ in. board. For mounting the tapestry, a stretcher should be made like that over which an artist's canvas is strained, cut from ¾ in. lath, 2 in. wide, and the tapestry should be tacked tightly over it. N. M. proposes protecting his needlework both at front and back with glass. If

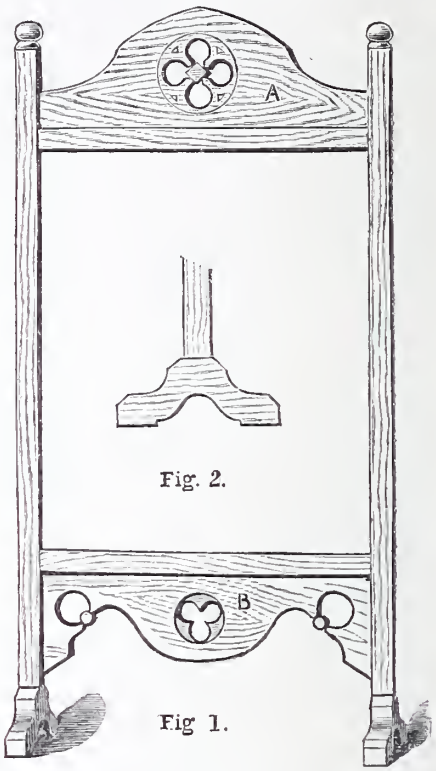

Fig. 2.

Fig 1.

Cheval Screen.

he does so, his simplest and most effective way of fixing it in will be with a narrow gold moulding, fastened to the frame with needle points. If his material is—as it most probably will be—soft wood ebonised, the gold will look especially well. I do not, however, see the necessity for glass: it will make the screen heavy and clumsy, and will always be exposed to danger, whilst the introduction of it will greatly increase the maker's difficulties. I advise him to do without it. A few dowels will then serve to keep the panel in place, and when the framework is tightly brought together round it and pegged, the whole will look solid and workman-like. The boards A and B will be fixed in shallow mortises in the uprights, and may run in V-shaped grooves in the cross-pieces.—M. M.

**Oxide of Cobalt.**—WORKITE.—You can dissolve black oxide of cobalt very easily in hydrochloric (muriatic) acid; but if you have any difficulty, warm it. Use the hydrochloric acid mixed with an equal volume of water. You might get out most of the yellow colour from the clay by warming the clay with dilute hydrochloric acid, allowing the clay to settle, and decanting the liquor. Wash well with water till free from acid.—F. B. C.

**Glass for Fountain.**—A. B. (*Aberdeen*).—You can obtain the above from Messrs. J. & W. Smith, of Farringdon Road, E.C. Ask for a 10 in. glass consumer with a hole in centre, as used for hall lanterns.—C. M. W.

**Small Engine.**—INQUIRER.—This is *too much* to ask for in a correspondence column. The drawings would take two days to make, and fill a page of the paper. Wait for some short paper on a small engine to work your 2½ ft. long model with a propeller.—F. C.

**Zinc Fern Case.**—J. D. (*Glasgow*).—An illustrated article on the construction of a Wardian case in zinc and glass is in the hands of the Editor. If the design is not just what you want, you can, of course, modify it to any extent; the general instructions, pattern of metal, etc., will hold good.—C. M. W.

**Gas Matters.**—W. H. B. (*Southsea*).—You will find on p. 541 of Vol. I. a similar question to yours answered under the heading of "How to Read the Index of a Gas Meter," with illustrations or diagrams. There is a misprint in the sentence in brackets; it should read 1,000, and not 1,090, as printed. You will find, on p. 422 of Vol. II., another answer to a question under the heading of "Gas Meter." There are also various other answers on the above subject, which you will find very useful; so you see that, although you have been a subscriber from the beginning, you have hardly been a constant reader. Your query as to "Why a consumer should pay so much for the hire of the meter when he does not have to pay a tradesman for the use of weights and scales and measures he uses?" only wants a little explanation, and I think you will acknowledge that the two cases are not analogous. For instance, the cost of a pair of scales and weights with which a tradesman can supply, say, five hundred customers would mean the cost of five hundred meters to the gas company before they could supply a like number of consumers—that is to say, it would cost the company about five hundred times as much for scales or measures as it would a tradesman. It would seem, at the first glance, that as the purchase of meters costs the company so much, and therefore must be paid for either directly or indirectly, the fairest way for them to charge would be to add so much on to the price of their gas or commodity, and get paid for them in this way, as in the case of the tradesman, though to a much greater extent. But this would hardly be right, for say the price of gas was raised 5 per cent. to pay for the purchase and repair of meters, then A, who burns, say, 1,000,000 ft. a quarter and has only one meter, would be paying out of all proportion to B, who only burns, say, 1,000 ft. a quarter and has one meter likewise; and yet A is a far better customer than B, and really is more entitled to a reduction than an increase in comparison to B, whose custom hardly pays for the initial expense of laying on the gas and fixing the meter. Therefore, in paying so much a quarter for the hire of a meter, the customer who burns the least gas pays more for it on the average than the one who burns most, and this, I think you must own, is the fairest way. We now come to your next point—viz., "That there is sometimes a considerable decrease in the consumption of gas for a certain time, through the fact of not having used it so often as usual; that, on the inspection of the meter index by the inspector appointed for that purpose, it has created a suspicion that something must be wrong with the working of the meter; but, on the other hand, if the meter registers ever so much more than the usual average of consumption, there is no remark made, no matter how one watches and economises the consumption." This cuts both ways. For example, if it is wrong for the gas inspector to doubt the meter when it does not register as much as usual, it is almost as wrong for you to doubt it when it registers ever so much more, but you both have your remedy. If the inspector doubts the meter, he has it tested; this puts you to little inconvenience, and costs you nothing if it is right and he wrong. If, on the other hand, you doubt the meter, you can have it tested by the Government inspector, and this would cost you nothing if you were right and the meter found to be wrong. Of course, if you have the meter tested and it is found to be all right, it is only proper that you should pay the expenses, and this would be but a very small sum but some inconvenience. But the improved way meters are now made and periodically inspected makes the remark, "To lie like a gas meter," practically speaking, an untruth, especially in the case of dry meters. You can get a very good idea if the meter is working properly by lighting one or more burners whose burning capacity you know. For instance, suppose you light four burners that are supposed to burn 5 cubic ft. each per hour—20 ft. per hour—then if, at the expiration of two hours, the meter has registered about 40 ft., you know that the meter is not far out. I have generally found, in practice, that a burner burns more than the amount stated. You can generally tell the number of feet an ordinary burner is supposed to burn by a number stamped on it or the number of rings chased round it near the earthenware top. A detailed description of the construction and working of a gas meter, with illustrations, would be far too long a subject for the columns of "Shop." I quite agree with you that it would be interesting to a number of readers, and, with the Editor's permission, I will write an article on it later on.—E. D. ["How to Control the Gas Meter" will shortly appear in WORK.—ED.]

**Lantern Microscope.**—S. C. W. (*Bristol*).—Microscopic slides, unlike ordinary lantern slides, require to be placed close to the objective in a lantern microscope. In this manner the small 3 in. by 1 in. slide is brought close up to the apex of the cone of light emitted by the condenser, which should be about four to six inches distant from the slide. The ordinary form of lantern microscope is generally supplied with two objectives, for the purpose of exhibiting slides having a diameter of 1 in. and ½ in., these lenses usually having a focus of 1½ in. and ¾ in. respectively. The objectives may take the form of a pair of plano-convex lenses of short focus mounted in a tube with the crowns of the lenses close together (as in an ordinary condenser), the foci varying from ¼ in. to 3 in., according to the power required; or, if preferred, the low power may be a pair of short focus bi-convex lenses, and the high power the ordinary achromatic form made to pass plenty of light. It is not always advisable to utilise microscopic objectives for lantern purposes, as lenses of this description are not always suitable for the purpose, and, moreover, they do not pass sufficient light. The body tube of the lantern microscopic, which is illustrated in Fig. 1, is made to screw into the draw tube of the lantern front in place of the ordinary objective, which is removed for the purpose. This body tube is provided with an inner spring tube, which retains the microscopic slides in position when they are inserted through the opening at the front end of the tube. This inner spring tube takes the form of a short length of tubing covered with a disc of brass at one end, which is pierced with an opening 1 in. in diameter, in order to admit the rays of light to the slide. A strong spiral of wire is coiled round the interior of the tube, and acts as a spring by forcing the tube towards the outer opening. In the better class of instruments this spring tube is held back while the objects are being inserted by the action of one or two milled screws. The objectives are mounted in separate tubes, so that they may be readily slid into a short adapter, or jacket, which is made to screw into the diminishing collar attached

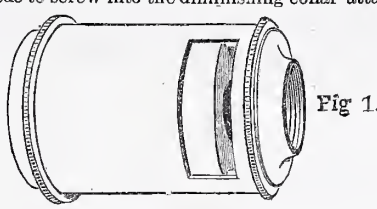

Fig. 1.

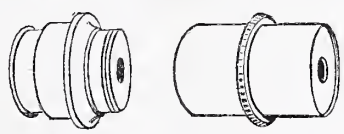

Fig. 2 Fig. 3.

Fig. 4.

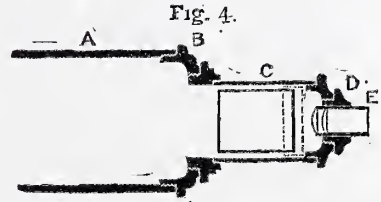

Fig. 5.

**Lantern Microscope. Fig. 1.—Body Tube of Lantern Microscope, showing Inner Spring Stage. Fig. 2.—Objective to screw into Diminishing Collar of Body Tube. Fig. 3.—Extra Power to slide into Objective Mount. Fig. 4.—Microscope with Double Stages shown at A, A; B, Objective. Fig. 5.—Section of Microscope—A, Draw Tube of Lantern Front; B, Collar of Draw Tube; C, Body Tube of Microscope; D, Objective Mount; E, Objective Tube fitted with Lenses.**

to the front end of the body tube. The focal adjustment is secured either by simply sliding the tube containing the objective in and out of the jacket, or by means of a rack and pinion attached to the latter. In Fig. 2 the high power is shown inserted in the jacket or adapter; and Fig. 3 represents the low power mounted in the short tube. Fig. 4 represents a better form of lantern microscope provided with double stages (shown at A, A) and clamping screws for the same; also an objective working with a rack and pinion adjustment, B representing the extra power which can be inserted in the rackwork tube when required. Fig. 5 is a section of the lantern microscope illustrated in Fig. 1, showing the disposition of the various portions. In the better class of lantern microscopes the light emitted by the large condensers of the lantern is received by a supplementary achromatic condenser, which reduces the pencil of light to a proper size; then follows an alum trough and the object holder for 3 in. × 1 in. slides; and in front of this the magnifying apparatus as in a tube microscope, consisting of a special achromatic objective, and an eye-piece giving considerable amplification and a wide field. The pencil of light is adjusted by means of rackwork attached to the small condenser, and the image is received upon a tightly strained paper screen, the adjustment being completed by means of a rack and pinion in connection with the objective. The lime-light alone should be employed with the lantern microscope, as no other form of illumination is capable of supplying a light of sufficient intensity to produce good results. As the heat rays emitted by the source of light are very nearly brought to a focus upon the small microscopic slide, it becomes necessary to interpose a small tank, filled with a solution of alum, between the condensers and the object, in order to absorb the heat rays, and thus protect the object from damage. There are many other matters to be dealt with in the construction of a lantern microscope that render it impossible to properly treat the subject in the form of a reply. A paper may possibly appear at some future date. In the meantime, you will find some additional information in Mr. A. A. Wood's manual, entitled, "The Magic Lantern: How Made and How Used." A description of a superior form of lantern microscope for use with the lime-light appeared in No. 29 of *The Magic Lantern Journal*. Several papers on Lantern matters will appear in the next volume of WORK.—C. A. P.

**Receipt of Deposit.**—GARTON.—Our correspondent is quite in error in assuming the receipt of the *deposit* of the application for the grant of a patent is provisional protection. When the papers he has lodged have been examined and accepted, he will then receive the grant of provisional protection. As, however, he states that he is "his own agent," he may pretty surely count upon the return of his specification for correction or alteration, as it is quite impossible for anyone who has not had a practical training and experience in patent matters to produce a document which shall meet the needed requirements. The Comptroller of Patents stated in his evidence before the Committee that "the *bad* specifications, as a rule, will be entirely those made by the applicants themselves; and the *very bad* ones are undoubtedly made by the poor inventors. It is clear that, nine times out of ten, it is *impossible* for the poor inventor to draw up his own specification in English!" In a late case before Mr. Justice North, where it seems the inventor had prepared his own documents, the learned judge said, "The plaintiff *not having been wise* in preparing his own specification, the defendant was equally *unwise* in preparing his own defence." Mr. Justice Field has said, "We all know the *sad difficulties* in which inventors are placed by reason of *want of care*, and sometimes *want of knowledge*, in preparing their specifications and drawings. It is a branch of learning which I have never yet succeeded in acquiring, and probably my life will not be long enough to enable me to do so. Many and many a perfectly good and perfectly valuable invention has been *absolutely defeated* by some *little mistake* of the *most trifling description* in a claim which was, perhaps, of no value at all." It may be taken as a positive fact that an inventor is about the *worst* person to be entrusted with the unaided preparation and completion of the documents required for obtaining a valid patent, inasmuch as there are such a great number of points requiring careful attention, wide experience, extended practical knowledge and skill, and the power of expressing, in a correct and significant manner, *what* the invention is, and *how* it is to be practically carried out, and *what* has to be protected, with the knowledge of *how* this should be done, which very rarely, if ever, is found in an inventor, and nearly as seldom in not a few of the professed "obtainers" of patents; that every inventor and intending patentee cannot be too careful in his proceedings in this direction. It is quite true that the inventor or intending patentee *must* know better than anyone else *what* his invention is, *what* he wants to do, and *how* he proposes to do it; but it must not be forgotten that the mere fact of this being the case does not, therefore, qualify him for those duties which can alone be properly carried out by those who have devoted their time, thoughts, abilities, skill, and experience *specially* to this object. It might as well be argued that, because a man is owner of a steamship, he is therefore able to navigate her or to fulfil the duties of chief engineer, and take charge of the engines and machinery. An inventor who has received provisional protection for his invention should be very careful in his proceedings, for there may be a prior application for the subject-matter of his invention, the provisional specification of which may be wide enough to admit of the comprehension of his plan in the complete, and for this he has no remedy; unless he can prove that his invention came to the knowledge of the party, and was appropriated by him, he is nowhere. We should advise our correspondent not to treat with anyone until he has filed his complete and received notice of its acceptance, especially if his invention is novel, useful, and likely to be of public benefit. Why will inventors with no knowledge of patent matters, or experience in the required proceedings, meddle with what they know nothing about? Can they expect for one moment to achieve a successful result? or can they think that the existence of a mass of invalid, useless patents will cause the capitalist public to look with favour on what is always a ticklish kind of security to have to do with? It should not be forgotten that every *penny* saved (?) in having the documents *properly prepared* will generally be found to result in requiring the expenditure of a great many *pounds*, and, in nine cases out of ten, ending in the loss of the patent. It is to be hoped that increasing intelligence and understanding upon patent matters will convince

inventors and intending patentees that the possession of an invalid and useless patent is no advantage to the owner nor any security for a capitalist, and that in future they will see that it would be wiser to abstain from meddling in matters of which they are entirely ignorant and have had no practical experience.—C. E.

**Buying Lathe Heads.**—A. V. S. (*Westbourne Grove*).—You can buy a head-stock, poppit, and rest at a tool shop; they are regularly sold for carpenters, cabinet makers, etc., who wish to make wooden bed and frame themselves. You can also get them at shops where they sell second-hand machinery, or by watching the advertisements in WORK. Try Caplatzi. £2 should buy a fairly good set second-hand.—F. A. M.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Blowing Fan.**—WAREHOUSEMAN writes:—"Will any reader of WORK enlighten me as to the best fan or air propeller for clearing a large warehouse of its vitiated air?"

**Rubber Rings.**—INDIARUBBER writes:—"I shall be glad of information as to machines for cutting rubber in rings."

**Coal Dust.**—HOUSEHOLDER writes:—"I have—in fact, have long had—large quantities of coal dust in my cellars and outhouses. Will any reader tell me of the best means of utilising it, and what to cement it with, if I wished to do so?"

**Galvanised Iron.**—COLONIST writes:—"Will some reader of WORK mind explaining the process of galvanising iron—the pickling, spelter, galvanising, and corrugating?"

**Hollow Stay Bolts.**—ENGINEER will thank any experienced in the work to explain the rolling of hollow stay bolts.

**Rock-Boring Drills.**—MONT CENIS will feel obliged to any reader who will acquaint him with the best rock-boring drills—hand or steam—upon the market.

**Corrosion in Steam Boilers.**—AJAX writes:—"Will any expert give me the cause and remedy for this?"

**Phonograph.**—RALPHO writes:—"Will some practical reader oblige by giving full particulars and drawings of a phonograph? I think there are a great number of readers who are clever enough to make one."

**Enamelling Fretwork.**—G. F. R. (*Bournemouth*) writes:—"Will any reader give me any hints through 'Shop' as to the best way to enamel fretwork? I have tried a good many things, but they are not quite a success. I find that the enamel brings the wood out rough, especially cross-grain, no matter how smooth I make it first."

**Cutting Clothing.**—DODO writes:—"Would any subscriber to WORK give information as to cutting out men's clothing, or where a treatise can be purchased? A system such as the Cosmopolitan, which ladies use for cutting their dresses, would answer."

**Whip Handles.**—G. L. (*Westminster*) writes:—"Could a worker in the trade kindly tell me how to prepare holly-sticks for whip handles?"

**Venetian Blinds and Glass Mending.**—H. R. (*Chacewater*) writes:—"Will some kind reader tell me the best material for mending glass or china; also where I could get Venetian blind laths, punched or unpunched, wholesale?"

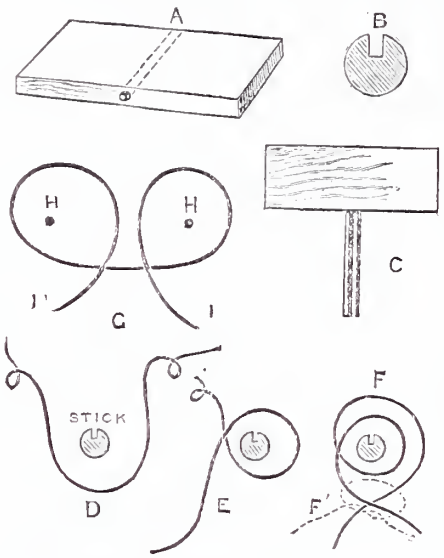
## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Brass Lacquering.**—L. L. H. (*Falmouth*) writes:—"As I understand L. M.'s query (see p. 637, No. 144), he wishes a pair of iron hames to appear as if they were of brass. This is practically impossible. If they are already covered with brass, and merely want re-lacquering, he could get it done through any good ironmonger, or even do it himself by polishing the brass-work thoroughly with Putz pomade, and then giving it a coat of the Silico Enamel Company's brassoline. If he is in any further difficulty about the matter, I should recommend him to write to one of the harness-making firms at Walsall, who would put him in the way of getting exactly what he wanted."

**Luminous Paints.**—EDDIFRA writes, in answer to R. R. (see p. 137, No. 144):—"Orange: 46 parts varnish are mixed with 17·5 parts prepared barium sulphate, 1 part prepared Indian yellow, 1·5 parts prepared madder lake, and 38 parts luminous calcium sulphide. Green: 48 parts varnish, 10 parts prepared barium sulphate, 8 parts chromium oxide green, and 34 parts luminous calcium sulphide. Yellow: 48 parts varnish, 10 parts prepared barium sulphate, 8 parts barium chromate, and 34 parts luminous calcium sulphide. Blue: 42 parts varnish, 10·2 parts prepared barium sulphate, 6·4 parts ultramarine blue, 5·4 parts cobaltous arsenate, and 36 parts luminous calcium sulphide. Violet: 42 parts varnish, 10·2 parts barium sulpbate, 2·8 parts ultramarine violet, 9 parts cobaltous arsenate, and 36 parts luminous calcium sulphide. Grey: 45 parts varnish, 6 parts barium sulphate, 6 parts calcium carbonate, 0·5 parts ultramarine blue, and 6·5 parts grey zinci sulphide. Yellowish-brown: 48 parts varnish, 10 parts prepared barium sulphate, 8 parts auripigment, and 34 parts luminous calcium sulphide."

**Besom Makers.**—H. M. S. writes, in answer to L. S. D. (see p. 635, No. 144), asking for address of besom makers:—"I might say that they can be obtained from the Liverpool workshops for the Outdoor Blind, Liverpool, where they make them."

**Rope Door Mats.**—E. P. B. (*Penge*) writes, in answer to J. A. (*Southwark*) (seo p. 590, No. 141):—"There are many varieties of mats made from old rope, but from your correspondent's statement that he has 'tried pricking a bole through canvas, and putting rope through,' I imagine he means the kind known as 'thrummed mats,' in the manufacture of which a thrum board is used. It is constructed by boring a hole through the edge of a piece of 1 in. board (size of board may be about 18 in. by 6 in.), A, and driving into it a stick about 18 in. in length of which B is a transverse section. C is plan of board complete, and *modus operandi* is as follows: Having unlaid the strands of a piece of rope—preferably coir, but alternatively bemp or manilla—and again unlaid these strands into their constituent yarns, the board is placed upon a chair—groove up—and used as a seat by the operator, with the stick projecting between bis legs. He then, taking a length of yarn about a yard from its centre, and holding it in both hands, dips the bight under the stick, as at D; one end is then taken over and down (E); the other follows in same way (F). All is hauled taut, and an assistant—who sits facing the operator—with ordinary seaming twine ties an overhand knot at each crossing, as shown by dotted lines at F, keeping same tight up under stick. This is continued until stick is full, when a sharp knife is drawn along the groove in stick, cutting each bight, and leaving a stick-length of thrum sennit, which



Diagrams for Rope Mat Making.

is sewn into mats with palm, needle, and twine. The yarns, after unlaying, should be made up into lengths of, say, about 20 yards for convenience sake, with a split overhand knot. When only very short lengths of old rope are available, they may be used by stretching two yarns parallel to each other, and then (having previously cut all yarns to exactly the same length—about 3 in. or 4 in.) taking a hitch round the stretched yarns, as at G (where H, H, are yarns and I thrum), hauling well taut, and, in progress of work, driving yarns well together. There are also paunch, sword, sennit, and canvas mats, of which I could send description, but fear it would be too lengthy for 'Shop.' The latter, however, is simply made by threading a large roping-needle with yarn (working on the bight), and, having folded canvas into a ridge, sewing yarn through it over a round stick with groove in it, along which a knife is passed to cut bights of stitches, and thus form thrumming."

**Copying Apparatus.**—C. R. (*Ealing*) writes, in reply to C. F. C. (*Oldham*) (see p. 637, No. 144):—"The address of the Auto-Copyist Copying Apparatus Company is in London Wall, E.C."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—E. A. M. (*Stockwell*); N. R. W. (*Colne*); BLUE EARTH; W. C. (*London, W.C.*); S. S. (*London, W.*); N. B. (*Wellington*); R. T. W. (*Leicester*); S. C. T. (*Knutton*); S. J. (*Stockport*); H. R. (*Colne*); N. J. N. (*Birkenhead*); MODEL S. L.; A. R. (*Scorrier*); C. T. (*Bradford*); J. J. (*Park*); W. M.; C. G. M. (*Penistone*); R. M. (*Croydon*); A YOUNG BEGINNER; R. G. (*Settle*); LEARNER; P. E. J. (*Tipton*); W. H. (*Bradford*); S. E. C. (*Warrenley*); KALLITYPE; W. H. B. (*Hastings*); D. P. (*Birstall*); J. P. (*Jubbulpore, East India*); G. H. B. (*Horsham*); S. D. (*Harmondsworth*); W. S. (*Cambridge*); A. R. R. (*Yarmouth*); W. S. A. (*London, N.W.*); F. R. (*Stapleford*); K. L. (*Leeds*); H. E. L. (*Stockton*); W. J. R. McG. (*Sale*); G. E. B. (*Ipswich*); RUBBER; E. H. (*Bethnal Green*); W. H. C. (*London, S.E.*); J. W. (*York*); G. P. O. (*Clapton*); W. W. (*Brentford*); CORKSCREW; C. B. S. (*New Wortley*).

## MANUALS OF TECHNOLOGY.

EDITED BY PROF. AYRTON, F.R.S., AND RICHARD WORMELL, D.Sc., M.A.

**The Dyeing of Textile Fabrics.** By Prof. J. J. HUMMEL, F.C.S. With Numerous Diagrams. Seventh Thousand. 5s.

**Steel and Iron.** By WILLIAM HENRY GREENWOOD, F.C.S., M.I.M.E., etc. With 97 Diagrams from Original Working Drawings. Fifth Edition. 5s.

## A DISSERTATION ON WALL DADOES.

BY FREDERICK PARSONS, F.S.Sc.

EXPLANATORY — RETROSPECTIVE — THE ANCIENT POMPEIAN DADO — RENAISSANCE — ELIZABETHAN — HANOVERIAN — MODERN DADOES: THEIR UTILITY — DECORATIVE VALUE — EXAMPLES OF MODERN DADOES IN VARIOUS STYLES AND MATERIALS.

IN some preceding numbers of WORK it has been my privilege to call its readers' attention to the subject of modern wall coverings, and in connection therewith to the province and value of colour. Therein we concerned ourselves with, respectively, the nature and qualities of materials, and the value of colour as a visual means of expressing and conveying sentiment. With a further view to making these fragmentary efforts a means of practical advice and assistance in their entirety, I purpose again to revert to the subject of materials, and therewith to deal, in a necessarily condensed form, with the general practice of dividing and sub-dividing wall surfaces into the divisions known as dado, filling, and frieze.

The dado, as a *common feature* of apartment and staircase walls, is an item of very modern and rapid growth. Ten years ago the technically "strongly flavoured dish" which my head-line suggests would scarcely have been considered interesting matter to such a heterogeneous mass as the intelligent readers of WORK. At that time "Lincrusta-Walton" was in its infancy; Japanese leather papers were the latest novelty amongst the high-price and West-End decorating firms; whilst "Anaglypta," "Alabastine," and many other strong claimants for attention to-day had then no commercial existence. If we are desirous to know what factor has caused the dado to become a "common hack," we have only to consult the enterprising paper-stainer's book of next spring's goods, and find therein dadoes, borders, and fillings, "made to match," at a retailing price of less than 6d. per roll of twelve yards. Well, I suppose none of us need feel personally aggrieved at this "levelling down" of an ancient and honourably connected feature. No one is materially the worse if Mrs. McCarthy, with natural envy of Widow Malony's "illigant dado," hies herself forthwith to the local glass, putty, and paper shop, and makes a like purchase. Not in the least. But very few of us can forbear making mental comparisons between "mind and matter," when, as is often the case, we find these cheap and usually pleasant wall coverings a direct antithesis to the crumbling structure, filthy and unwholesome surface, that lies beneath their bright exterior. "As we sow, so must we reap;" and therefore, if by reason of unrestrained judgment the paper-stainer makes worse than common the association of his "wall papers, with dadoes to match," the discredit, as well as commercial ill-effects, must be borne by them also.

*Retrospective.*—In order to remove from the mind such prejudice as the above-mentioned circumstance may raise, and to gather some idea of the respect that is due to our subject, we must turn back the pages of time, not merely ten or a hundred years, but to the dim past ages of the great Roman Empire—to the period when those beautiful cities, Pompeii, Stabiæ, and Herculaneum were so tragically buried beneath the streams of molten lava and showers of cinders vomited forth on the 24th of August, A.D. 79, by that monster of destruction Mount Vesuvius.

Although it is probable that were we to explore minutely the still more ancient remains and records of Egyptian, Chinese, and Grecian decoration, we might come across earlier examples of dadoes—sur-base divisions—on wall surfaces; nevertheless, it was not until the ancient Roman artists—and particularly those of Pompeii—worked out their elaborate and fanciful schemes of painted wall decoration that the dado became as definite an interior division as the pilaster and frieze.

The Pompeian treatment, as will be seen on reference to the diagram Fig. 1, did not consist only of a horizontal line, which merely divides the wall flank into two (upper and lower) divisions—now termed by us *filling* and *dado* respectively—but the latter was really the superficial and decorative sur-base of one complete effect. We may not stop here to analyse the proportion of dado to panel (or filling), of panel to pilaster, and so forth. It is, however, advisable to point out that considerations of utility had little or no place in the arrangement of the sub-divisions or their subsequent embellishment. Like as in the Japanese and the Italian Renaissance styles of design and decoration, the Pompeian artists studied to produce effects pleasant simply to the senses—the æsthetic province of decoration. Those amongst my readers who apparently, like the contributor of a certain tirade against purely ornamental beauty of design, have not yet learned to appreciate anything but *phonetic—mind-speaking*—ornament, should not fail to spend an entire day in that beautiful reproduction of a Pompeian house at the Crystal Palace.

Fifteen hundred years after these classic Roman ages, Italy was stirred throughout by a re-awakening—Renaissance—of art and architecture. Then were the sites of ancient cities and the remains of classic art fully explored, and the artistic work of those middle ages was consequently much influenced by the discoveries and studies relating thereto. It is not to be wondered at, therefore, that we find elaborate division and painting of wall surfaces a special feature of also the Italian Renaissance decorations.

*The Elizabethan style* of ornamentation was to a great extent an offshoot of the Renaissance, and in this period dadoes and high-panelled wall divisions were much in vogue. Although it might be suggested that a wooden dado notion is such as might have come naturally to the mind of the native Elizabethan architect—at a period when the English oak and a good stone wall were the chief building considerations—it is more probable, one would think, that the custom was brought over from the Lowlands—a sign as definite as the Elizabethan ornament itself of the influence of the *Flemish* phase of the great Renaissance.

*The Hanoverian period*, although anything but remarkable for its contemporaneous works of architectural or decorative excellence, brings to our minds the influence and life's work of two eminent architects—the Brothers Adams. We cannot now discuss the purely artistic merit of the interior ornamentation originated by these men of much respected memories; it is sufficient here to note that the arrangements of design alluded to are noticeable in their prominent display of panelled and sub-divided surfaces, also by a lightness and delicacy—almost to frivolousness—of the ornamental detail; and, further, in natural connection with the first characteristic, a general use of dado and frieze. From all this it is evident that the Pompeian style was a source of inspiration to the Adams Brothers in all respects—save that of the degree of conventionalism in which the detail was drawn and the substitution of ornamental *relief* form for the strong, sensuous colouring of the ancients.

With the foregoing cursory glance over the historial associations of the dado we must rest content—our work is of the present, not the bygone ages.

In dealing with the *modern dado* and its "thousand and one" variations of style, material, and treatment, one's professional experience—at all times subject to some limitations—is here the only source to be drawn upon. If the memory is taken back to the days immediately preceding the introduction of Lincrusta-Walton, now approaching twenty years, the influence of the Adams' style was still very marked. In the West-End districts of the metropolis, and encased within the ugliest of square brick-built houses, beautiful designs of the above type were repeatedly met with, and, in fact, many are still preserved. With these examples continuously before him, the modern professional decorator quickly availed himself of the dado division as a means of contrast and decorative display for the new materials—which productions, by reason of their expense or great richness and elaboration, it was not expedient to hang all over the walls. Having now defined the source of the modern dado's popularity—fashion, alas! being almost as rampant in house decoration as with ladies' clothing—it is superfluous to trace it through the various stages of rarity and generality down to the before-mentioned depths of trashy degradation and misuse. There is still one minor feature in connection with dadoes yet unmentioned. For many years past it has been an occasional plan with builders to divide a parlour wall by a "chair-rail." The fixing of these bands of more or less moulded wood-work—usually of anything but an elegant nature—for the purpose of preventing the tops of the chair-backs from knocking the plaster wall, although, no doubt, adopted as a "clever notion," is not a very commendable practice. A chair-rail proper is a piece of moulding fixed at the *base of the skirting*, where it answers the purpose equally well in keeping the chairs from the wall. Again, the height of a chair-back is scarcely a guide for the proportion of dado to filling—anything but that—whilst the notion of getting first the chairs, then the wall to suit the chairs, suggests some very absurd combinations. It is, therefore, scarcely fair, I think, to the modern dado to associate its origin with the old chair-rail.

*The utility of the modern dado* is a subject presenting a twofold aspect: viz., first in connection with "wear and tear," and secondly, that relating to its usefulness as a purely *decorative* feature. There is, however, at least *one* leading principle common to the introduction of both, and this—*that the more the lower portion of a room wall is likely to be hidden by furniture the less suited is the apartment for a dado.* Simple and common-sense enough as this principle is, one seldom finds it carried out in practice. We may often see in a modern house the dining-room dado panelled all around alike, so that when the occupier's sideboard and buffet is *in situ* many yards of expensive panelling is hidden. Had the architect used a commensurate amount of time and material for making an inexpensive fixed sideboard in character with the dado, both the artistic and commercial issues would have profited. Again, in the modern drawing-room, dadoes have been "pushed" alarmingly by the paper-stainer, whereas the expense is literally thrown away; half, or

more, of the dado is unseen, and even that latter portion, instead of serving as a foil and background to the best furniture and accessories, more often detracts from the shape and outline of such goods. It is thus patent to us that the usefulness of the dado division not only varies with different apartments and the uses to which they are put, but is further intimately concerned with the style and arrangement of the furnishing. In connection with the homes of the "masses," a dado division will prove very economical for staircase, passage, and kitchen. Nothing can compare with a light and cheap filling division of distemper, both for effect and cleanliness; and when the surbase is painted either a darker tone of the same colour or a dark contrasting colour, wear and tear is well provided for. The practice of pasting paper over paper until it forms one mass of putrefying vegetable nastiness has probably caused ten times more sickness than ever the presence of arsenic in wall papers has been responsible for. Cheap papers are more related to the percentage of interest on house property investments than to any other artistic or useful consideration. If every dwelling-house had the same attention from Government inspectors as is given to the workshop and factory, many would benefit therefrom. We should certainly have better finished walls, lighter and more cheerful interiors, and far purer air to breathe if the cheapest wall paper cost 2s. 6d. per roll, for it would then be recognised, of necessity, that plain tints of distemper formed the best cheap covering.

*The decorative value of the dado*, although a subject of less practical interest to my readers, calls for a few sentences. In the first place, the base division of a wall breaks up the monotony of the surface mass. The dado, however, has no material connection or association with the *build* of the wall. Even with costly wooden dadoes these are always attached as accessories, surface treatments, and as such must be considered part of the furnishing. One of the effects of a dado is to convey a snug, "closed-in" sentiment, and which, when carried to extremes of proportionate height, gives the impression of "sitting in a well." Therefore, by reason of the horizontal *tendency of line*, the feeling of *sur-base support*, and the *scope for contrasting colour*, the dado as a purely decorative factor is invaluable in the embellishment of our homes. In design they should never be "patch-worky," *repose* being a desideratum. Where there is full scope for display a dado of rich-looking relief material is very effective, care being taken that the form of the furniture is always helped by the contrast of pattern as well as tone. Imagine a shaped wooden chair-back placed against a dado space covered with a stiff design of something between a Chinese puzzle and a Gothic ceiling pattern, and you will understand "what not to do," my reader. With regard to *colours* combined with pattern, the fewer the better in a dado. Next to one general colour, the most suitable treatments are soft monochrome effects, whilst all strong subdivisions of line or assertive contrast in colour, and—unless in the nature of a highly raised leather paper—all gilding and metallic colours should be avoided for the dado of an *ordinary apartment*.

*The examples of modern dado* materials which are given on page 753 should serve to emphasise some of the various points I have herein drawn attention to. Their height, it will be observed, varies considerably, but in dealing with the average room the height of the top of the door lock-rail gives a useful proportion of filling and dado. The latter should never, unless with high wooden panelling, come above the mantelpiece, and the aim should always be to work in the line of rail, or top border, with some pre-existing structural feature of the room. Beyond mere consideration of colour and oil paint, the materials adaptable to dado purposes are innumerable. American oil-cloth, India matting, cretonnes, Turkey twills, brown paper (bought in continuous rolls and finished with painted decoration), plain "oil-grounded" papers, and the great variety of ordinary wall papers, Lincrusta-Walton, Willesden paper, Tectorium, leather papers, Alabastine, Anaglypta, and many more could be added to the list. Our worthy Editor will surely say, "Hold! enough!"

## THE WINTER ELECTRICAL MACHINE AND ACCESSORY APPARATUS.

BY CHAS. A. PARKER.

THE GOLD LEAF ELECTROSCOPE—PROOF PLANE—PITH BALL ELECTROSCOPE — HORIZONTAL ELECTROSCOPE — PITH BALLS — HENLEY'S QUADRANT ELECTROMETER—SPANGLED TUBE—LUMINOUS NAME-PLATE—ELECTRICAL SWING—ELECTRICAL SEE-SAW—ELECTRICAL MORTAR—HENLEY'S UNIVERSAL DISCHARGER—EXPERIMENTS WITH THE DISCHARGER—CONCLUSION.

THE *Gold Leaf Electroscope*, which is depicted in Fig. 56, will be found a most useful piece of apparatus to possess when studying the phenomena of induction, or for the purpose of detecting minute charges of electricity. It consists of a couple of narrow strips of gold leaf attached to a flattened piece of brass rod, to the upper end of which a flat disc of metal is affixed, the leaves thus prepared being enclosed in a glass jar mounted on a wooden stand. For the glass jar an ordinary chemical deflagrating jar will be found to answer very well; or, failing this, a "comet" pattern domestic lamp chimney may be made to serve the purpose fairly well. It will be necessary to employ the largest size of this pattern chimney, which will measure 6½ in. high and 2½ in. diameter; any oilman or ironmonger can supply these at about 3d. each.

When a suitable glass jar has been procured, the next proceeding will be to provide it with an ornamental turned wooden base, which should be furnished with a slight groove, into which the glass may fit. In the absence of anything better, the base may be made in a simple manner from a cigar-box lid by cutting out a couple of discs, one of which is made to just fit into the jar, with the other one about ¾ in. larger. These two discs may now be glued and clamped together firmly, and when dry, a disc of foil of suitable size is pasted on to the upper surface of the smaller disc. A couple of narrow strips of tinfoil—about ½ in. wide, and nearly half the height of the jar—should now be pasted inside the glass jar on opposite sides, in order to serve as a means of discharging the gold leaves if they should become overcharged at any time.

We shall now require a 5 in. length of stout brass wire, one end of which should be softened in a gas flame, and then bent to the form shown in Fig. 57, the lower portion being hammered quite flat, in order to afford an attachment for the gold leaves. A small disc of brass must now be soft-soldered to the bent portion of this wire in the manner indicated by the dotted lines in Fig. 58, and when this has been done it will be necessary to insulate the wire, and then fit it into the cap of the jar. The wire is heated in the centre, and then provided with a thick cylindrical coating of shellac, which should be made to flow evenly round the wire for about a couple of inches along its length, being rolled whilst hot between the fingers until of a uniform diameter, about the thickness of an ordinary cedar pencil. Thus prepared, the whole is inserted in a hole previously bored in good sound cork of a suitable size to fit into the opening at the top of the jar. If desired, a small turned wooden cap may be glued on to the cork, in order to form a better finish.

The wire will now be ready to receive the gold leaves, which, by the way, should be the real article, and not Dutch metal, as the latter is much too harsh for our purpose. A leaf of gold should be gently coaxed from its containing book on to a sheet of clean note-paper, which is then folded and cut into strips about 2 in. long and ½ in. wide, using a pair of sharp scissors for the purpose. Both sides of the flattened end of the brass rod should be moistened with just a trace of glue or gum, after which the two strips of gold leaf are attached to the rod with the greatest possible care. It will be necessary to hold the breath while the leaves are being manipulated, otherwise they may become crumpled and blow away. When ready, the wire should be quietly and gently introduced into the jar, with the leaves hanging perfectly parallel to the foil strips attached to the sides of the jar. It is necessary that the leaves should be just clear of the glass on either side when they are greatly diverged.

The glass should now be cemented on to the wooden base, after which the air should be sucked out of the interior by means of a glass tube inserted in a hole bored for the purpose through the cork, the aperture being closed with a dab of sealing-wax immediately afterwards. It will add considerably to the appearance of the instrument if the under-side of the disc and the top of the cork or cap is painted over with a coat of red sealing-wax varnish.

A *Proof Plane* (which is shown in Fig. 59) will be found very useful to employ when charging the electroscopes. It can be readily made by simply cementing a brass knob or thin disc of sheet brass with perfectly smooth edges into a suitable length of glass tube of small size and bore, as shown in the illustration.

The *Pith Ball Electroscope* (see Fig. 60) is another form of electroscope, which may be readily made in the following manner: One end of an 8 in. length of soft glass tubing, ¼ in. in diameter, is first drawn out to a fine point in a Bunsen flame, and is then bent in the form of a curve, with a small hook at the end, as shown in Fig. 60. Thus prepared, the larger end is cemented into a hole bored for its reception through the centre of a small ornamental turned wooden base, which is afterwards painted with enamel spirit varnish. This done, the pith ball is suspended from the hook of the supporting stem by means of a single filament of "cocoon" silk, which is drawn through the ball by means of a needle, and then knotted at the end.

The *Horizontal Electroscope* depicted in Fig. 61 is another description of electroscope, which takes the form of a straw balanced on a needle-point mounted on a short length of glass tubing, and attached to an ornamental turned wooden base. First prepare a small turned wooden base about 2½ in. in diameter, and then provide this with a hole in the centre, into which a 2 in.

length of soft glass tube is cemented. Previous to the tube being cemented into the base, draw out one end to a fine point by means of a Bunsen flame, and then, holding a small sewing-needle point outwards in a pair of pliers, proceed to fuse the thick end of this into the drawn-out end of the glass tube, being particular to see that it is quite true with the tube.

The glass stem having been cemented into the wooden base, the latter should receive a coat of spirit enamel, after which it will be ready for the straw. For this we shall need a perfectly straight 9 in. length of sound wheat straw, which will require to be mounted on a small metal pivot to act as an axis. To make this pivot, take a piece of stout brass wire, and having first filed one end to the form of a cone, cut off a $\frac{3}{16}$ in. length, and then drill a small hole longitudinally towards the apex of the cone, afterwards cementing the pivot thus formed into a hole burnt through the middle of the straw by means of a hot wire, after which a small pith ball is glued to either end of the straw. This hole in the pivot will naturally require to be drilled perfectly true, in order that the straw may balance correct, and be capable of twisting round at the slightest influence.

The *Pith Balls* above mentioned can be readily cut to the spherical form from a piece of perfectly dry elder pith, using a very keen razor for the purpose. When cut, the balls may be gently rolled beneath a flat board, in order to remove any little irregularities of surface, care being taken not to crush them. Bundles of pith, suitable for this purpose, can always be obtained from any watchmaker's tool warehouse at 2d. each.

*Henley's Quadrant Electrometer* (shown in Fig. 62) will be found a very useful instrument for ascertaining the tension or amount of electricity collected on the prime conductor. It takes the form of a graduated semi-circle of ivory or celluloid attached to a vertical rod, which can be readily mounted on the prime conductor of the machine. From the centre of the graduated disc a light pith ball is hung on a pivot, and as the latter flies up the scale as the machine is worked, it is considered to indicate the amount of electricity developed. The graduated scale may be prepared from a thin piece of mahogany, cedar, celluloid, or vulcanite, which is carefully cut to the semi-circular plan shown at A in Fig. 63, with a slight projection at either end, in order to provide for its subsequent attachment to the supporting stem.

The component parts of the electrometer are shown full size in Fig. 63, but if desired, it can be made larger or smaller, provided that the dimensions are kept proportionate.

Having got the scale roughed out, take a pair of compasses and strike out three semi-circles, about $\frac{1}{8}$ in., $\frac{1}{11}$ in., and $\frac{1}{16}$ in. distant from each other, after which all the divisions should be carefully marked in black, red, or Chinese white, according to taste. A small piece of thin sheet brass is now cut to the plan of B, Fig. 63, and afterwards bent into the form of a tubular hinge, in which one opening crosses the top of the other, as will be seen by reference to C, Fig. 63. This hinge is now pivoted in the axis of the scale by means of a short brass pin or stud riveted into a hole prepared for its reception in the scale, care being taken to see that the hinge moves with perfect freedom.

The scale is now fitted tightly into a slot of sufficient length and width, which is filed half-way through a $4\frac{1}{2}$ in. length of brass tube of small diameter (D, Fig. 63), after which a small brass ball (E, Fig. 63), provided with a hole of sufficient diameter, is made to fit over the upper end of the tube, thus securing the scale in position, an ordinary brass screw (F, Fig. 63) being finally soft-soldered to the lower end of the tube, in order to afford a means of attaching the electrometer to the prime conductor of the machine. A very thin round match (G, Fig. 63) or a sound straw is now cemented into the opening in the central hinge with a small pith ball (H, Fig. 63) affixed in a like manner to the lower end of the match. It will also be found convenient to have a small turned wooden base on which to support the electrometer when not in use.

The *Spangled Tube*, or luminous hand spiral, illustrated in Fig. 64, is a very interesting piece of apparatus for showing the effects of the discharge when passed through a series of small bodies nearly in contact. Take an 18 in. length of $\frac{1}{2}$ in. or $\frac{3}{4}$ in. soft glass tubing, and having carefully cleaned the inside by means of a piece of rag tied to the end of a string and drawn through the tube, warm the air contained within the tube in order to dry it, and then tightly fit a good sound cork into the opening at either end, afterwards cutting the ends off flush with the edges of the tube.

Now take a sheet of tinfoil, and having laid it on a metal surface (preferably zinc) cut off a few strips $\frac{1}{8}$ in. wide by the aid of a keen-edged penknife and a ruler, being careful to cut the foil perfectly clean and free from ragged edges. Thus prepared, the strips of foil are stuck round the glass tube in a spiral form by means of shoemaker's paste, care being taken to lay them on the glass perfectly true and free from creases, after which any superfluous paste is wiped off with a damp cloth, and the tube placed aside until quite dry. When thoroughly dry, the foil must be cut up into a series of hexagonal pieces by means of the penknife drawn across the strips in the manner shown in Fig. 65, in order to remove all the shaded portion shown in the above illustration.

As the glass rapidly blunts the knife, it will be necessary to frequently sharpen it on a hone. At this stage of the proceedings one end of the tube will require to be provided with a brass ball of suitable size: an ordinary ottoman ball will be found to answer the purpose admirably, as the screw stems with which these balls are provided will enable it to be screwed into the cork of the tube, care being taken to see that it is in metallic contact with the foil. The other end of the tube should have an $\frac{1}{2}$ in. strip of foil pasted round the glass, with about $\frac{1}{8}$ in. turned over on to the cork, and a small disc of foil pasted over the flat end. It will also be found convenient to have an ornamental turned wooden base on which to support the tube in a vertical position.

The *Luminous Name-Plate*, depicted in Fig. 66, is a slight modification of the spangled tube, by means of which it is possible to show illuminated names or devices, which have a very pretty effect when viewed in a darkened room. The design or word is formed by pasting a number of small hexagonal pieces of foil on to a sheet of glass of suitable size, with horizontal strips of foil pasted in lines across the glass, in the manner shown in Figs. 66 and 67. Thus prepared, the glass is mounted in a wooden frame, which is supported on a glass stem attached to an ornamental turned wooden base. A small brass knob is now affixed to one of the upper corners of the frame in contact with the top horizontal lines of foil, and a small hook is attached to the opposite lower corner in a similar manner. In use, the discharge is passed in the usual manner from the upper knob along the horizontal lines of foil, and out by means of a piece of chain suspended from the hook at the lower end of the frame.

The *Electrical Swing* and *See-saw*, shown in Figs. 68 and 69, are a couple of amusing pieces of apparatus for showing the phenomena of attraction and repulsion. Taking the swing first, a piece of sound dry mahogany, measuring 6 in. by 4 in., is carefully planed up on the face and edges, and then provided with four supporting feet in the usual manner. This done, a couple of 7 in. lengths of glass rod, $\frac{1}{2}$ in. in diameter, are cemented into a pair of turned wooden sockets furnished with short projecting pins, in order to provide for their subsequent attachment to the base. Two small hollow brass ottoman or stool balls, of a suitable size to fit over the tops of the glass rods, are then provided with small brass hooks, which are soft-soldered into holes drilled for their reception in the side of each ball, after which the latter are cemented on to the upper ends of the glass supports.

The projecting pins of the wooden sockets of the glass rod are now glued into a couple of holes prepared for their reception on opposite sides of the base, with the hooks of the brass caps facing each other on the inside. A small brass ball is next soldered to one end of a 2 in. length of stout brass rod, the other end of which is then pointed by means of a file, and afterwards pushed firmly into the wood-work at one end of the base. When this has been done, another hollow brass ball is provided with a small brass hook in the manner before described, and is then cemented to the end of a 2 in. length of glass rod, which is afterwards glued into a hole of suitable size, bored for its reception, at the other end of the base.

A small pith figure, cut and painted to form a neat little doll, about $1\frac{1}{2}$ in. in height, is now mounted on a thin flat piece of pith, which forms the seat of the swing. This figure is afterwards slung between the two insulated pillars of the stand by means of a silk thread passed underneath the seat of the swing, and up through a couple of holes on either side, the upper ends of the silk terminating in small loops, by which it is suspended from the hooks of the insulated supports.

When in use, the swing is connected with the machine by means of a short length of chain, brought from the prime conductor, and hung from the hook of the conducting rod at the back of the base, another piece of chain being suspended from the insulated ball at the front of the base, in order to provide the necessary earth contact. If properly adjusted, the figure will steadily swing backwards and forwards during the time that the machine is worked.

The *See-saw* (which is represented in Fig. 69) is but a modification of the swing just described, and is of extremely simple construction, as will be understood by reference to the above-named cut. For the base, a piece of mahogany, 10 in. by 3 in., is carefully smoothed by means of a plane, and then provided with four supporting feet as usual. This done, a couple of 3 in. lengths of in. glass rod must be cemented into suitably turned wooden sockets, each of which should have short projecting pins turned underneath, to enable them to be glued into a couple of holes bored through the base—on opposite sides—by means of a centre-bit.

When these two supporting pillars have been attached to the stand, two short brass

Fig. 76.—Section of Table.

hooks should be fitted and soldered into holes drilled through the sides of a couple of hollow brass balls, which are afterwards cemented to the ends of a pair of 1½ in. lengths of glass rod, these rods in turn being cemented into holes prepared for their reception at either end of the wooden base. A very thin lath of dry wood, 10 in. in length and about 1 in. wide, must now be pivoted between the two insulated supports by means of a darning-needle thrust through the width of the wood exactly in the centre.

A couple of hollow brass balls of suitable size, to fit the supports of the plank, should now have a small hole drilled through the side of each, after which they are cemented on to the upper ends of the supports, with the strip of wood pivoted between them by inserting the ends of the needle in the holes in the brass balls. The see-saw is finally completed by gluing a suitably carved pith figure on to either end of the balanced plank, after which it may be set in motion, in a similar manner to the swing previously described, by means of a couple of short lengths of brass chain hooked on to the conducting knobs—one of the latter being placed in communication with the prime conductor, and the other with the earth.

An *Electrical Mortar* (shown in Fig. 70) is employed for the purpose of exhibiting the deflagrating powers of the discharge. It is formed from a block of hard wood, about 2 in. square, which is turned in a lathe to the form shown in the cut, and then provided with a hole ¾ in. in diameter, which is bored from the upper side through to about half the thickness of the wood. A couple of short lengths of brass wire are now bent in the form of a small ring at one end by means of a pair of pliers, and then rounded off at the other extremity by the aid of a file. Thus prepared, they are now tightly fitted into a couple of holes bored through the block on opposite sides at ¾ in. below the mouth of the mortar, as it may now be called.

When ready, the mortar may be charged with a mixture composed of equal parts of chloride of antimony and chlorate of potash, which should be separately powdered, and then mixed together carefully by means of a feather. It is important to crush these substances separately; otherwise, if they are pounded together the mass will be inflamed. A sufficient quantity of the powder is put into the mortar to just cover the two conducting wires, one of which is now attached to the outer coating of the Leyden jar or battery, and the other to the discharging rod, by means of short lengths of brass chain, and when the discharger is brought into contact with the inner coating of the jar or battery, it will cause the charge to pass and fuse the mixture.

In *Henley's Universal Discharger* (which is represented in Fig. 71) will be found an almost indispensable piece of apparatus for use with the Leyden battery. The base should be prepared from a piece of sound dry mahogany, ¾ in. thick, carefully planed to measure 10 in. by 4 in., and then furnished with three holes, which are bored through the wood by means of a ⅜ in. centre-bit, one being situated in the middle of the board, with the others at about an inch from either end. Three small ornamental wooden sockets to receive the supporting glass rods are now turned in a lathe to the form of Fig. 72, and then fitted into the holes in the base by means of the short projecting pins. The openings in the sockets should have a depth of about 1 in. and a diameter of ⅝ in., and as soon as they are ready a 2 in. length of ½ in. glass rod may be cemented into the central socket, with a couple of 4 in. lengths of the same diameter for the other two.

When this has been done, it will be necessary to prepare two hinged caps for the upper ends of the last-named glass supports. For each of these, mark out and cut a piece of moderately stout sheet brass to the plan of Fig. 73, then bend the piece of metal thus obtained round the glass rod, and afterwards solder the seam neatly together, thus forming a metal cap with two projecting leaves. The tubular portion of the hinge is now formed from another piece of sheet brass, which is marked and cut to the plan of Fig. 74, and then head round a piece of $\frac{3}{10}$ in. brass rod, after which the two leaves are soldered together, in order to make the hinge as solid as possible. The two portions of the hinge thus formed are now riveted together by means of the head, and a short portion of the stem of a brass screw, which is passed through holes bored for its reception through the outer extremity of each portion. When completed, the hinges, which will present the appearance of Fig. 75, should be cemented on to the upper ends of the two onter glass supports of the base, after which they will be ready to receive the two metal arms.

For each of these arms a 10 in. length of brass rod, about $\frac{3}{10}$ in. thick, should be bent in the form of a small ring at one end, and then pointed at the other extremity, after which the pointed end of each arm should be tapped to screw into a small ½ in. brass ball. It is necessary for these balls to be removable, as it is sometimes desirable to screw others in their place. As soon as the arms have been completed, the glass supports to which they are attached may be made a fixture to the base, and when this has been done a small mahogany table, 3 in. in diameter, should be turned in a lathe to the form of Fig. 76, with a short socket on the under-side, which is made to fit the upper end of the central glass stem of the table. A longitudinal or circular recess is now cut in the upper surface of the table, into which a piece of ebonite is carefully cemented, after which the surface must be accurately levelled, and the table finally cemented on to the upper end of the glass supporting stem.

The table should not be cemented into the central hole of the base, as it is sometimes convenient to remove the table altogether for the performance of certain experiments. It is also usual to provide a small screw press, which is capable of being attached to the base in place of the table, as may be required.

This press consists of a pair of small mahogany boards, mounted in a horizontal position on a glass stem, in a similar manner to the inlaid table above described, but provided with a couple of vertical adjusting screws and wing nuts, which are affixed to the lower board at either end. The body through which the charge is to be sent is placed in position between the press, the screws of which are then tightened and the discharge passed in the usual manner. Correctly speaking, the arms of the discharger should be mounted on the supporting stems by means of ball and socket joints, but for all ordinary purposes of the amateur experimentalist the above modification of this form of joint will be found to answer extremely well.

*Numerous experiments* may be performed by the aid of Henley's Universal Discharger and the Leyden battery before described, the charge being passed through various substances placed upon the table of the discharger. Arrange the arms of the discharger to within about a couple of inches of each other, and then slightly unscrew the ball, and insert a thin slip of tinfoil between them, afterwards screwing the balls up again. Now connect one of the arms with the outer coating of the Leyden battery by means of a short length of brass chain, and then attach another length of chain from the director to the other arm of the discharger. If the battery is now charged and the ball of the director is rapidly brought in contact with the other arm of the discharger, it will cause the entire charge of the battery to be passed through the strip of foil, which is instantly fused up with a brilliant flash.

A slip of gold leaf arranged in a like manner will also be fused, as also will other metals, silver leaf resulting in a bright green flash, and Dutch metal a purple tint. The strips of metal employed for this purpose—which should not exceed ¼ in. in width—may be readily cut by enclosing the leaf of metal between a sheet of writing-paper, and then cutting the required width by means of a pair of scissors. An ordinary visiting card or a few sheets of note-paper, supported on the table of the discharger between the knobs of the arms, can be pierced by the discharge, which will produce a slight burn on either side of the card. If the knobs are placed nearly in contact on the table of the discharger, and some tow is arranged between them, and then sprinkled with a small quantity of powdered resin, the latter will be inflamed upon the charge being passed.

When the spark is passed in the ordinary manner between the brass balls, it results in a brilliant violet flash, but if these balls are removed and a pair of ivory balls substituted, it will assume a crimson tint, or a pair of copper balls silver-plated will colour the spark green.

Various substances placed upon the table of the discharger, with the arms in contact, will assume different tints upon the charge being passed: rock crystal becoming red, sulphate of barium or lump sugar green, chalk orange, and calcined oyster-shells the prismatic colours, etc.

## ON SOME WORKSHOP APPLIANCES.

BY H. J. L. J. MASSÉ.

BENCH: IMPROVEMENTS ON AND UNDERNEATH IT—VICES—SPARE TABLE ROOM—CLAMP—FLAP FOR ADDITIONAL TABLE—TOOL CHEST—GAS SUPPLY.

A DESCRIPTION of some of the appliances I have fitted up in my workshop at different times may be of interest to some of your readers; and as some of the devices are quite inexpensive, they may, perhaps, in some cases, be adopted, or they may supply hints on which other contrivances may be fashioned.

To begin with the bench, as this is an indispensable article in any workshop. Mine is one of the smaller size of German benches, standing about 31 in. high, and measuring 50 in. by 18 in. I found this quite high enough when I began to work only occasionally at woodwork, but found it too low to work at for any length of time, so I raised it slightly from the floor by putting a piece of quartering under each of its two legs. These two legs are really rough pieces of framing, kept firmly in place by two struts, which fit into mortises and are wedged in. On the struts rests a board, on which the jack and trying planes are kept, and below them are a couple of boxes for odds and

ends of all sorts—bits of leather and bits of wood, all of which are sorted periodically into different boxes for future use. One of the first things I added to the bench was a bench-stop—known as the "Perfect"—which, as many readers of Work know, is fixed in flush with the bench top. The stop can be adjusted to any height by hand, either under the bench or from the top, and is fixed or released by a half-turn of a screw, also sunk flush with the bench.

Later on I bought and fitted to the bench a joiner's instantaneous grip-vice, a tool which, without any unscrewing, will take in anything, from a sheet of paper to a block 12 in. in thickness, and hold it "like a vice." This vice is all very well for wood-working, but it is quite unsuited for holding small pieces of metal, and it is too low down—being only 35 in. from the floor—to enable one to do much filing satisfactorily. As I had a small parallel bench-vice with 3 in. jaws, which I used to screw on to a table or bench when required, I mounted it on a piece of plane-wood (30 in. by 5 in. by 4 in.), which I had bought for turning, but which, working out rather rough, was discarded. This block, then, with the vice on the end of it, is placed in the jaws of the instantaneous grip-vice, and can be held there at any height most convenient for the job in hand. If the grip-vice is in use, the block can be fixed in the sliding end of the bench, which is in itself a vice, and held there at any height. Sometimes, too, it suits me to sit down with the block and vice held tightly between my knees, and resting on the floor.

Everyone, even the tidiest among us, has sometimes felt how nice it would be to have another table (no matter how small) to hold some small thing that has been just recently cemented or otherwise repaired, well out of reach of everything else. This end I was able to attain by making a table out of an old drawing-board, about 2 ft. by 15 in., with pieces of wood screwed to the under-side in the shape of a capital H. The cross-bar of the H is held tightly in the jaws of the small vice on the block, and the block inserted and held in the instantaneous grip-vice. In this way I have ready at hand a table which can be adjusted to any height and almost any angle I happen to want. It has been a most useful contrivance, and as I often like to stand up after a long spell of sitting, it is a real comfort and a great economiser of time: *e.g.*, suppose I am in the middle of a piece of repoussé work or chasing, and the kitchen clock is sent up to be put to rights, with a message that everybody is waiting for it; or a toy is brought in by an imperious youngster, who means to wait till it is mended, the table can be rigged up high and dry above everything else in a moment—there is no clearing away of tools, and no delay in returning to the work originally in progress. I often grip in my big vice a board 4 ft. by 11 in. by 1½ in. when I want the bench temporarily widened for mount cutting, or any large piece of work.

The back of the bench has a lath attached, between which and the bench chisels and files can be put, and to hooks on the legs of the bench two tenon saws and a small panel saw are suspended.

Another useful addition to the bench is an American bench-clamp. It is a difficult tool to describe, but it somewhat resembles an F. The top arm and the upright pillar or shaft are made of one piece of round steel, a little over an inch in diameter. In the end of the arm a screw works, and this screw raises or depresses the lower arm as required. This lower arm is 16 in. long, and moves between four spurs or studs on the shaft; it can thus be brought up close to the shaft or kept 16 in. away from it. The shaft is merely inserted into a hole in the bench—I have three holes in mine, one at each end and one in the middle—and the object to be clamped is put under the end of the movable arm; and then the more turns that are given to the screw in the top arm the tighter the article is clamped to the bench, and the tighter does the shaft hold in the hole in the bench.

This clamp is most useful for holding down a plank flat on the bench while planing or bevelling it, for pressing together two pieces of wood that have been glued, or for holding a thin sheet of metal while turning the edge down on to a wooden shape held underneath. By clamping a piece of board (about 3 ft. long) under it at right angles to the bench a convenient table for fretwork is formed, under which one can sit and move about with perfect freedom.

Another table in my workshop, which is used occasionally for picture framing, mount cutting, but chiefly for photographic and chemical work, is really nothing more than a strongly-built kitchen table, measuring 6 ft. by 3 ft., which stands against a wall. Seeing that after giving up a foot all along its width to a chest or nest of drawers, the space left is sometimes insufficient, I have a plank which, by means of loose edge hinges (*i.e.*, hinges which can be unmounted in a moment), can be fitted to or removed from the table with the greatest ease. This plank is kept in its place by a small button at the end of the table (otherwise the hinges might work loose), and is held up by two arms which, being pivoted at both ends under the table-top, need only to be pulled out at right angles to the edge of the table to make a secure support for the flap.

My tool-chest takes the form of a cupboard (4 ft. by 3 ft. by 11 in.), which I have mounted on two boxes as pedestals. The boxes are placed on their sides, and their open tops which give on to the room form most convenient receptacles for such bulky things as boot-lasts, mitre-cutters, cramps, and the like. Between the two boxes there is a space, in which I keep a box for larger oddments in brass or copper.

The gas arrangements are the outcome of much planning. The gas bracket is a straight and rigid iron pipe with a connection for flexible tubing fitted to the end. By means of this I am enabled to run three tubes, each with a separate tap, from the one tube which constitutes my gas "main." The top pipe has a "Kinnear's" patent jet attached, a most useful invention, as it enables me to turn the gas down to a tiny bead, in case I am called away from my den, and it needs no relighting on my return. It is absolutely necessary in printing on alpha or bromide papers. This burner is the chief illuminating agent in my workshop.

Tube No. 2 is carried down by red india-rubber tubing to a position just above the bench, where it is attached to a double-swing gas bracket, about 22 in. long, fitted with a Swedish burner, opal globe and shade. With this I can work very comfortably at night and on dark days, as I can regulate the shadows that fall on any work to a nicety, and it is a good light for reading purposes.

Tube No. 3 is a longer length, nearly three yards, and is fitted to my blowpipe—a tool I could not do without—worked by one of Fletcher's foot-blowers. My object in having such a long tube is that I can have my blowpipe wherever I like in the workshop, or in whatever room I have occasion to transport the whole apparatus, for soldering or what not. I can also, by removing the blowpipe, fit the tube on to a gas standard on the lathe, where a good light is indispensable for good work. I can also, when in a hurry, very easily light my fire by inserting the lighted gas tube in among the coals; in this case no laying of the fire is required.

## A CLEVER CHAIN-COUPLING LINK.

BY JOHN W. HARLAND.

In looking over my diminutive "marine stores," into which I throw all items of metal, broken tools, screw-bolts, nuts, etc., in the hope that "they may come in useful some day," I came across a link of chain which, on examination, struck me as a very valuable invention. I cannot account for its coming into my possession; it bears no mark; it may

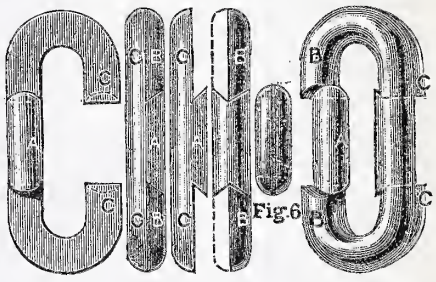

Fig. 1. Fig 4. Fig. 2. Fig 3. Fig. 5.

Chain-Coupling Link.

have been patented, for aught I know. I have shown it to several people who ought to have seen it if it had ever been in general use, but it is as new to them as to me. Perhaps someone of the hundred thousand readers of Work might know something of it. At any rate, it would be invaluable for military purposes, and as a reserve link in case of broken chains for railways, wharves, carriers, etc.

My sketches above show its beautiful simplicity. Fig. 1 is one of two exact counterparts of the form of a letter C. Between the points C, C, is a gap in each. Fig. 2 shows side view of same; it is in form (in profile) a half link with a portion of dovetail shape left on, full thickness, and round to fit the gap of the counterpart half link as shown fitted together in Fig. 4, Fig. 3 being the said counterpart. Fig. 5 shows these two half links slided almost into place. It is evident that when the neighbouring links are placed within one half link, and the other is slid into place, the stress on the chain will maintain the two half links in position so that they can never slip undone; the dovetail piece, A, being solid, supports the point, C, of the other half link, B, and, being dovetailed, all strains tend to press the two flat surfaces closer together laterally—binding them into one link, as it were. Fig. 6 is an end view of link with dotted lines showing dovetailing when in closed position.

Such pairs of half links could be cheaply made by machinery, and if made in steel would be stronger, if anything, than the links of the chain itself; at any rate, it would be a pity that so good an idea should be left to perish in obscurity. I shall be glad to know if any reader of Work has at any time met with a link similar to this.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

### The Dining-Room—The Fireplace.

*The Dining-Room.*—This room, which opened from the entrance-hall on the side opposite to the study, had, at the time when I entered upon the house, a decidedly more civilised appearance than that room. Some previous occupant had done his best to modernise, and, according to his lights, to improve it. The wide, open fireplace which it had formerly possessed (of the same kind as that in the "den," but on a somewhat larger scale) had been walled up, and instead of it had been inserted a rather handsome grate of the *delirium tremens* pattern in vogue thirty years ago. I apply this name to that particular style from the singular facility with which its cast-iron ornamentation resolves itself, when the spectator's nerves are a little out of order, into horrible monsters. By this alteration the length of the room had been diminished by some 3 or 4 ft., though it was still of fair size, viz., 18 ft. by 15 ft.

The walls had been papered. They had skirting boards, but no cornice. The doors, of which there were two, one from the hall and one opening to a passage leading to the kitchen, were panelled and fairly good. The one large window had once had handsome stone mullions, but these had been removed, probably for the sake of more light, and wooden ones of far less bulk substituted.

*The Fireplace.*—With one of the above "improvements" I would most gladly have dispensed, and that was the modern fireplace. The old open chimney, situated as it was at the end of the room and immediately opposite to the chief doorway, might have been made a highly effective feature. But restoring it to its original form was out of the question. I had to accept it as it stood and make the best of it.

The modern mantelpiece which had been put up was, if not ornamental, at least inoffensive. It was of blackened slate. On consideration, I resolved not to remove it; but if the reader will refer to Fig. 18, which represents this fireplace as it now stands, he will see that it has been pretty effectually concealed. The present mantelpiece, as there shown, is of carved oak on a background of ebonised pine; there are some old scraps in it, but the work is mostly my own. I made a frame of black wood, large enough to encase the slate jambs and lintel, and attached to it my twisted pilasters and carving. I then drilled holes into and plugged the slate, and fixed up the woodwork by screwing through the pine boards into the plugs, and thus succeeded in making my new mantelpiece perfectly firm and secure, without the trouble and mess of pulling down the old one, and without, what to me was a point of importance, the necessity of calling in the mason.

My new and larger shelf lies on the old slate one, which is hidden by a moulding fixed to the under-side of the shelf-board; a couple of strong dowels into the wall at back hold the new shelf in place. It is still further secured by the super-mantel, which is screwed to plugs in the wall, and rests upon and is dowelled into it.

I must admit that the carving about this

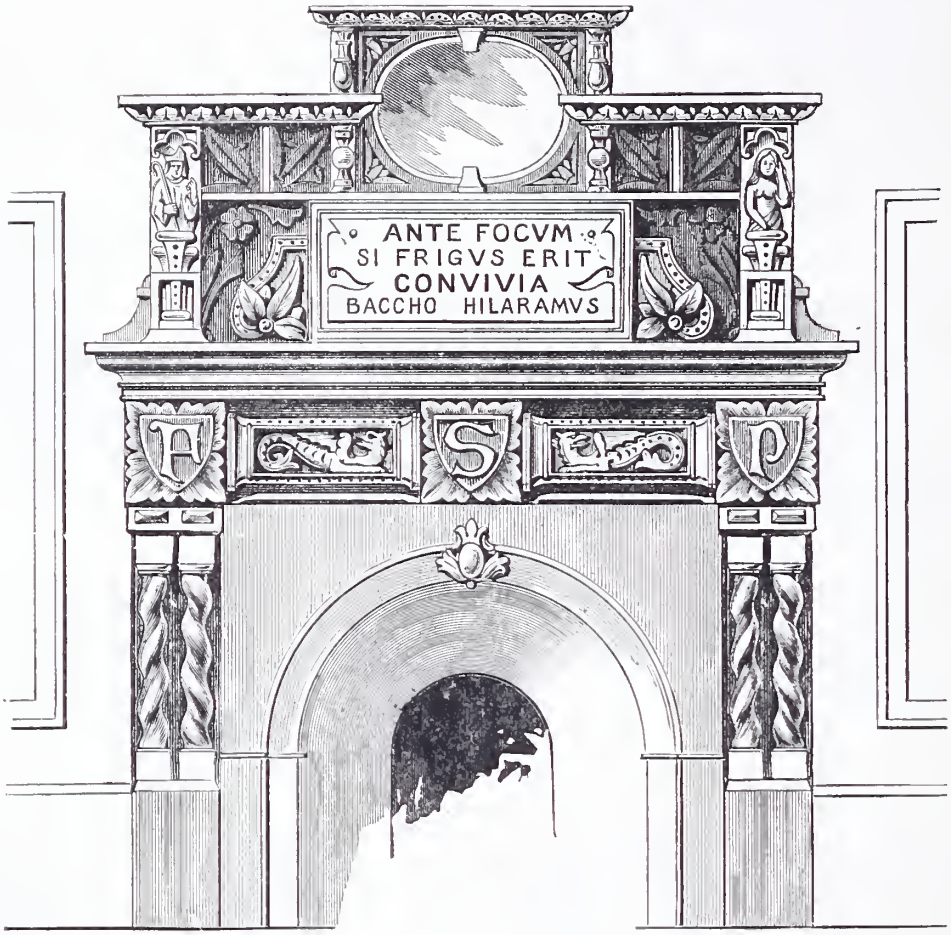

Fig. 18.—Dining-Room Fireplace in Carved Wood.

fireplace cost me considerable labour and time, perhaps more than most people would care to devote to such a purpose. But I imagine that one of its most telling features, namely, the twisted shafts, might very effectively be combined with turned and joinery work only, so as to be carried out more quickly, and by anyone who did not carve. These twists were cut by hand (not in the lathe) and they are readily made. The way to set them out is to wrap strips of paper spirally round the wood; a draft is then made with the saw up the hollows, which can afterwards be quickly worked out with the gouge, the work being finished with the file and glass-paper.

If, instead of a plain mantelshelf, one covered with velvet and edged with fringe should be preferred, such an arrangement will be found perfectly suited to the design, since a fringe 4 in. or 5 in. in depth will hide the mouldings merely, and not the carved work.

## CORK WORK.

BY J. W. W.

Old corks are generally considered useless litter, only fit to be burned, but there are few things that lend themselves more readily to the adornment of various articles; and anyone with an average amount of patience may turn out work that will, by its beauty, surprise both himself and his friends. Of course, I know there are many readers of Work who will consider themselves above this kind of work, but there are many more who, like myself, are willing to try their hands at any kind, so long as it goes toward the beautifying of their homes.

And now, having said so much in favour of old corks, I will proceed to give a few simple designs for those who should feel desirous of trying their hands at this kind of work. First, as regards cutting the cork: an old, thin-bladed table-knife, well sharpened on a rough stone, is the best tool, as far as my experience goes—and I have tried everything almost, from a small dovetail saw down to a pocket-knife—and should be used with a quick, firm pressure; it is impossible to cut cork by hitting or chopping.

Fig. 1 is a pretty design for a picture-frame. For this you will require a wood foundation, made out of $\frac{1}{2}$ in. by $\frac{3}{4}$ in. stuff, rebated out $\frac{3}{8}$ in. deep, and then half-checked together, leaving the ends 2 in. long—the broad side should be to the front; cut your corks like Figs. 7, 9, and 10, glue the three-cornered pieces on the sides close up to the front, and the half-rounds on the front close up to the edges, then glue the pyramids on down the middle; the three-cornered and half-round pieces are $\frac{1}{8}$ in. thick, and the pyramids are $\frac{1}{2}$ in. square at the base. For the corners where the frame is half-checked together, cut four flat-topped pyramids $\frac{3}{4}$ in. square at the base, and about the same height; it will greatly improve the appearance of the frame if these are blacked, but you must do it before they are glued on, as it is a difficult job to do after without smearing the others. The frame should now look like the corner shown at Fig. 1, and may be washed over with a thin coat of glue, to stop the pores; after which, it should receive two coats of shellac varnish, as that shows to more advantage than the more transparent kinds.

Fig. 2 is a design for a basket: filled with African everlasting flowers and prepared moss, this makes a very pretty ornament for a small bracket. Select a nice oval cocoanut, and cut it as shown, leaving the

handle about ⅜ in. wide (care must be exercised in extracting the nut, or you will break the handle off); this is covered with corks cut like Fig. 8, a row being glued on the top edge, another round the outside close up to the top, then four festoons, as shown. For the legs, gimp three corks, cut one end to a bevel, so that it fits the side of the nut, and glue them on equal distances apart. The handle and open spaces should be covered with cork cut very fine, or rice may be used for the same purpose—but if it is, the cork must be varnished first, as the rice looks best left as white as possible, and should be done with transparent varnish.

Fig. 3 is a cover for an ordinary flower-pot. To obtain the correct size and shape for this, wrap a piece of paper round the pot it is intended to cover, letting it overlap ½ in.; then cut it out in stiff cardboard, glue the overlapping edge, and tie it round the pot till dry. Now cut a circular piece for the bottom, with a ½ in. hole in the centre to allow the drainage to escape; a few strips of calico should be used in gluing this on, to make it more firm. The same design is used for this as for the basket, with the exception that the festoons are continued right to the bottom, one falling from the middle of the other; fine-cut cork or rice is used for filling in the spaces. If the pot is intended to stand in a saucer, the bottom may be left off, if thought well.

Fig. 4 is a very pretty design for a pair of spill-holders. The foundations for these are made out of stiff cardboard; the shape of the front is shown at Fig. 5, the dotted lines showing where it is turned up for the sides; strips of calico should be used to make the joints more firm. They are covered with corks cut like Fig. 8, a row being glued round all the edges and angles; the open parts are filled in with rice—bearing in mind to varnish the cork work first with shellac varnish, the rice being done after with transparent. A bow of ribbon is tied round the neck, and a loop attached to the top to hang them up by.

Fig 6 is a basket for ferns: any old box may be utilised for the foundation. A cigar-box does very well, if only a small one is wanted; it is covered with half-round corks, (½ in. thick) and pyramids (½ in. square at the base); a row of pyramids is glued on the top edge, then a row of half-rounds round all the sides; next a row of pyramids, and so on till there is only a small space left, which may be filled up with cork cut very fine. The feet are round pieces of wood driven into holes bored in the bottom, and then covered with fine cork; the handles are fastened to the inside of the ends with small screws, the cross-bar being fixed in place with a fine brad driven through all three sticks, then covered with fine cork, like the feet.

Of course, there is almost an endless number of things that may be ornamented with cork, but, having said so much in favour of cork work, I will leave the readers of WORK to follow their own taste, and exercise their ingenuity in finding out and fashioning articles that lend themselves conveniently to this mode of decoration. With regard to the execution of the work, or rather the cutting of the cork that is used for its decoration, the instructions given above must always be held in remembrance and acted on. Cork is in itself a material which is far more difficult to cut than harder substances, owing to its spongy and yielding nature; therefore it is imperative that a sharp tool should be used, and that the tool itself should be kept well sharpened. The cork worker should endeavour to provide himself or herself with cork of tolerably close texture, such as is used for phial-corks, and not of an open, spongy-like character.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Mouldings, Beads, Ovolos, and Ogees.

A frequent use of beaded edges is where boards are brought into contact, but not glued. If a large surface is to be boarded, it would be almost impossible to get timber so dry as to remain perfect joints; so in the familiar form of matched lining we have a frequent use of beads; when the boards shrink a little it gives the appearance of another quirk, making the bead look more symmetrical.

Around sashes, beads are prepared and added to the frame, making a neat finish, yet easily removed in the event of a broken sash-line. The amateur will more often require beads to lighten the appearance of his door-frames, and to break the continuity of folding doors, etc. It is advantageous to have beads to definite sizes, and to see that when the iron is fairly set the bead works true to its name, because frequently the parts of a framing have to be so fitted that allowance for beads, rebates, or mouldings must be made on the shoulders.

Sometimes the worker is able to evade this condition, as in sashes where the moulding on the face side is exactly compensated by the rebate for the glass, it is obvious that the rebate can be made to any size, and to make it the depth that the moulding removes leaves the setting-out of the work "square."

I mention these considerations because the amateur will now be buying bead and moulding planes, and he is advised to get them true to size; if, however, he has planes in hand, he had better make a set of mouldings with them, and keep the set thus made for reference.

The mention of sashes reminds us of ovolos. A variety of shapes and sizes of mouldings are covered by this term, which is derived from ovum, egg. The special feature of all these mouldings is some resemblance to a quarter of an ellipse; some, however, are founded on the quarter circle; usually the curve is detached from the flat surfaces by narrow flats, called fillets. If these flats are large in proportion to the moulding, they are to some eyes very ugly, and the quarter ellipse as a basis for the moulding is much more graceful than the quarter circle.

Another useful moulding is the ogee. This, which has a great variety of forms, consists of a hollow and a rounded surface in close contact, and melting, as it were, one into the other.

Many of these mouldings are—and more were—worked by the use of hollows and rounds: a useful set of tools, which will not often be required by the amateur. In such cases one or two hints may be of service. Prepare the stuff truly, marking out on the ends the profile required. All straight lines on the ends should be brought to the surface and marked thereon, care being taken to mark the moulding in a true plane—*i.e.*, not "winding." Use a plough if much wood is to be removed, and with rebate planes work the straight or flat portions, then with rounds work the hollows, finally using hollows to make the round members of the moulding. In cases where the moulding—as in a cornice—is set forward, the bevels at back should be made before using the hollows and rounds, and special care should be exercised to make sure of a true surface, for upon this largely depends success in mitring the moulding when finished.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 112.—The Homacoustic.

The instrument which bears this name, and is represented in the accompanying illustrations, is a new speaking-tube instrument constructed after Cutmore's patents. It is claimed for it that when used in connection with speaking-tubes, it entirely supersedes, for indoor purposes, all existing arrangements for inter-communication, including even the telephone, over which it possesses many special advantages. Taken with reference to speaking-tubes, it completely supersedes the old-fashioned mouthpieces and whistles, and does away with all the features that render them so objectionable—the principal of which is the necessity of blowing into the pipe in order to set the air therein in motion, and so sound the whistle at the other end of the tube. This is brought about by the bottle-shaped contrivance shown in each of the accompanying figures; for when the plunger at the top is pressed down, the pressure displaces the air and causes the whistle to sound, the instrument being thus automatic. When the whistle has been sounded to call attention at the other end of the tube, the operator lifts and holds to his ear the pendent tube which is seen hanging from the appliance, and speaks, when necessary, into the funnel-shaped orifice which is opposite the mouth. This arrangement entirely does away with the necessity and inconvenience of applying first the mouth and then the ear to one and the same orifice, as in the old-fashioned whistle-fitted speaking-tube, and messages can be simultaneously transmitted and received, and conversations can be carried on as if the speakers were in the same room and speaking in the ordinary way; and there is no inhalation of the breath injected into the tube by the speakers, as must inevitably occur when the old form is used, and the whistle is always in position. The mode of using the instrument is clearly shown in Fig. 3, and the Homacoustic itself, when not in use and when attached to a wall, is exhibited in Fig. 2. Of course, it will be readily understood that, in this case, it is only possible to operate on a single tube with the instrument. The different parts are as follows: A is the whistle placed at the top of a hollow plunger, B, which, when pressed, is forced into the globular metal casing, C, in which is placed an indiarubber ball, which, by its action, restores plunger and whistle to its place when the pressure that has been applied is removed; D is the mouthpiece into which the operator speaks, and projecting from the centre of the tube is a fixed hollow cane fitted with base, which acts as a baffle when the whistle is being sounded, and prevents the escape of the air otherwise than through the whistle itself; E is the flexible tube which is applied to the ear.

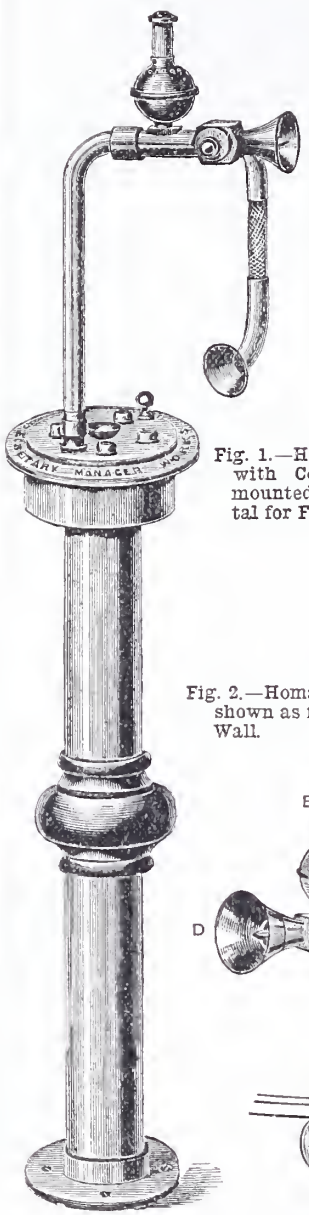

Fig. 1.—Homacoustic with Commutator mounted on Pedestal for Floors.

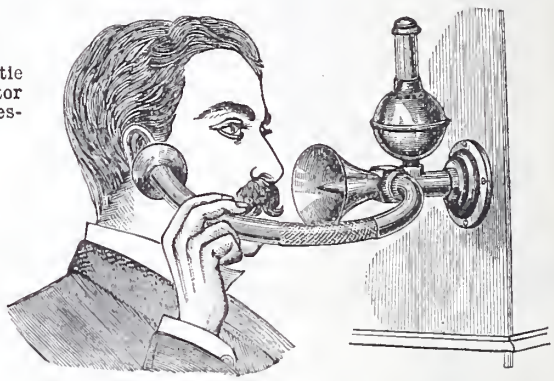

Fig. 3.—Mode of using the Homacoustic.

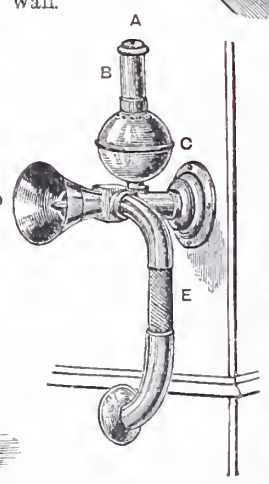
Fig. 2.—Homacoustic shown as fitted to Wall.



But one of the greatest advantages possessed by the Homacoustic is shown in Fig. 1, from which it may be seen that a single instrument is sufficient for operating on a number of tubes which are collected in a pedestal fixed to the floor and have their upper ends fitted into a strong metal base, the Homacoustic itself being fixed into a small circular switch-plate or commutator, which can be moved at pleasure to the right or left, thus bringing the end of the Homacoustic immediately over the orifice of the tube connected with the place or apartment with which communication is desired. It will be noticed that the room or department with which each particular tube communicates is indicated by lettering on the band in which the plate carrying the Homacoustic revolves, and the part of the building with which it must be connected by the simple act of moving the plate and bringing the instrument over the tube which is connected with it, is shown by an indicator shutter in the plate, which springs up as soon as the whistle is sounded. In a brief notice, such as this necessarily is, it is impossible to describe minutely the whole of the means by which the instrument is brought into use; but enough has been said to show its nature and its importance as an invention. It was invented and first used in Australia, and is now under the control of the Homacoustic Speaking-Tube Company, who possess patent rights in the instrument apparently in every country in the world in which such rights can be obtained. It seems to be a very meritorious instrument, and one which will find favour with the mercantile public when better known. The Editor.

## SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—LETTERS FROM CORRESPONDENTS.

**Central Foundation Schools Carpentry Class.** — A CORRESPONDENT writes:—"You may be glad to note that in the exhibition of carpentry and turnery recently held at the Central Foundation Schools, Cowper Street, London, several simple articles shown had been made from drawings which have appeared in WORK. A coal-box, a lady's table, a model kitchen table, a screen secrétaire, an easel, and two writing cabinets were among the simple articles made by members of the Carpentry Class under the direction of Mr. R. Scotter, the instructor; while others were being made during the exhibition at a bench near the stall. The other articles exhibited might be called specimens of the application of drawing to woodwork, designed to show how useful articles may be made from simple geometrical designs. Various examples of turnery were exhibited, several made at a lathe attached to the carpentry stall during the exhibition. I was glad to see the interest these boys had evidently taken in their work, and trust they may develop in after-life the taste which they have had opportunities of acquiring for making practical use of simple tools."—[We are glad to receive such satisfactory testimony as this of the successful adoption of technical training in schools, this being a matter which will always have our encouragement.—ED.]

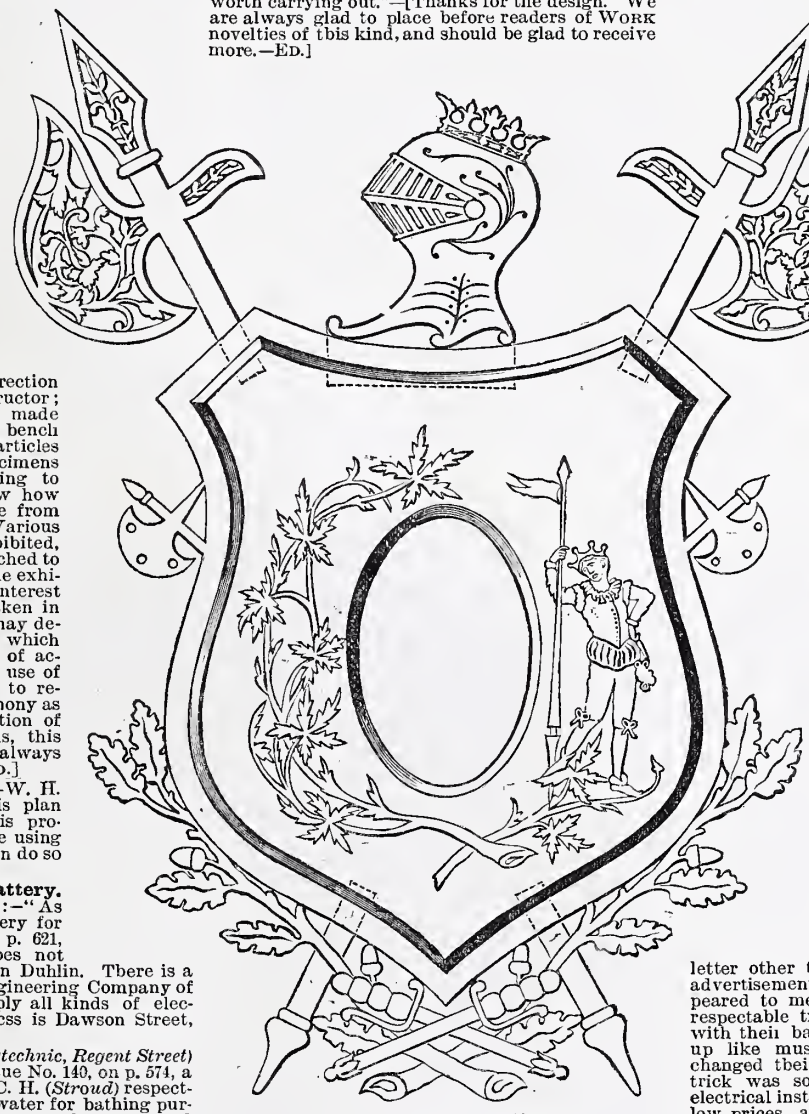
**Bicycle Anti-Vibrator.**—W. H. P. (*Tottenham*) writes:—"This plan (see WORK, p. 510, No. 136) is protected by patent, and anyone using or making the application can do so only by licence."

**Electric Night-Light Battery.** —F. G. M. (*Dublin*) writes:—"As regards the question on battery for electric night-light in WORK, p. 621, No. 143, G. E. B. says he does not know of any electrical firm in Dublin. There is a firm called the Electrical Engineering Company of Ireland, Limited, who supply all kinds of electrical appliances. The address is Dawson Street, Dublin."

**Bath-Room Air.**—B. (*Polytechnic, Regent Street*) writes:—"I notice in your issue No. 140, on p. 574, a reply to ROUND O (p. 414) by C. H. (*Stroud*) respecting a method for warming water for bathing purposes. As such a simple appliance as that suggested by C. H. is likely to be largely utilised by readers of WORK, may I, if you think the matter of sufficient interest to your readers, utter a few words of warning in connection with the ventilating of any room in which such an appliance is to be used? The bath-room is usually one of the smallest rooms in the house, and bathers, on entering a bath-room, invariably close the door and window so that they will not catch cold from draughts; then, so soon as they have stopped free access of air, they commence to strip while the water is getting hot. Now, by stopping the free entrance of air into the bath-room, it follows that the air left in the room is rapidly rendered impure by the inhalations and exhalations of air by the bather, and is made absolutely poisonous by the lighted charcoal in the stove using it for the purposes of combustion. Thus the pure air which the room had contained is rapidly replaced by the exceedingly impure products of combustion, formed by oxygen combining with the free carbon from the burning charcoal and forming carbonic acid gas, and, in smaller proportions, the very dangerous carbon monoxide. To ensure safety while bathing, it is necessary to either remove the stove out of the room altogether or else fit it with a loose cover to which a socket is attached, and this could be connected with a pipe, which should be so arranged that it would pass the products of combustion out into the open air. That there is very great danger in using these appliances when not properly ventilated is proved by the number of deaths which have occurred while using similar kinds of bath-heaters during the last few years."

**Locks.**—BRASS (*Wolverhampton*) writes:—"Two slight mistakes appear in my reply to J. G. (*Bloomsbury*) (see 'Shop,' p. 590, No. 141). In the first two addresses the letters *E.C.* should be omitted, as they are wrong and may mislead someone. The addresses are all of Wolverhampton, as stated further on, but at first sight one would think London was referred to."

**Fretworker's Photograph Frame.** —A. D. (*Monkwearmouth*) writes:—"I submit herewith an original design for a photo frame, which some of the fretwork readers of WORK may find useful and worth carrying out."—[Thanks for the design. We are always glad to place before readers of WORK novelties of this kind, and should be glad to receive more.—ED.]



Design for Fret Photo Frame.

**Hand Saws.**—CHOPSTICK writes, in reply to A. R. (*Scorrier*) (see p. 603, No. 142):—"I beg to inform him that he has read my former letter in quite a different way from what I intended it. If he looks again, he will see that I said nothing about the *rake* of the teeth, but was simply referring to the *shape:* which is quite a different matter. I was simply trying to do away with the ridiculous fancy shapes mentioned in the article. As to the proper *rake* of the teeth, that, of course, must be governed by the experience of the user, as an experienced man can work a saw with considerably more rake on than a novice; but the more the rake the faster it works, and also the more likely it is to run out of its course. A. R. mentions strength, but that is of very little use without experience, and that he will know as well as myself. He also seems to doubt my experience; but I can tell him that I have for this last twenty years sharpened all kinds of saws, from the dovetail to the pit saw in hand-working saws, and from a 4 in. to a 66 in. circular, and also band saws for steamwork. I began sawing in the pit when fourteen years of age, and had plenty of cross-cutting logs at the same time—and even younger; and if I had A. R. at one end of the cross-cut saw, and myself at the other, with an elm-tree 4 ft. in diameter between us, I could do more to convince him of my experience in cutting logs than I ever hope to by writing. However, I think he is a very good man at the job, though we do not both think alike; but I take it all in good part, and whatever he may say, I shall not write again on this subject unless the Editor wishes it. In reference to a former letter of A. R.'s, I assure him that I have written nothing, nor shall I write anything, except what I know to be true and practicable, as I certainly would not lead anyone astray. If ever I happen to be anywhere near Scorrier, I will look up A. R., and then, I have no doubt—no shadow of doubt whatever—that we should come together in some of our opinions, and part better friends than we met."—[This correspondence must now be closed."—ED.]

**Patent.**—C. E. (*London, N.W.*) writes, in reply to S. E. (*Upper Clapton*) (see p. 587, No. 141):—"Our facetious friend Artemus Ward gave a very sound piece of advice when he said, 'Don't prophesy unless you know.' I see in the first column of 'Shop' (p. 387, No. 141), S. E. says I have 'made a serious slip' in one of my communications, and therefore he hastens 'to correct it,' and says, 'If you or any of your readers rely upon this particular statement of his, they may regret it when too late;' but he may rest assured that I am *not* ready to admit my error in this case.' Now, if S. E. will just be plucky enough to invest one small sixpence in the purchase of the Patent Office 'Rules and Regulations,' which contains the fees to be paid on the various matters relating to patents, he will there find in print exactly what I have said, and I suppose he will accept this as correct. I am extremely obliged to S. E. for his kind solicitude on my behalf, and beg to thank him for it; but as he describes himself as an 'inventor,' and sets himself up as an instructor of the public, I will just modify Artemus Ward's advice to suit his case, by saying, 'Don't attempt to *teach* unless you *know*!' I must also thank him for giving a practical illustration in himself of the truth of what I have said in that part of my statement which he quotes at the commencement of his communication. Truly the race of persons ready to do what angels fear is not yet extinct."

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Glazier's Diamond.** — W. T. (*Llantrisant*). — The only firm I know of is a London firm — viz., Sharratt & Newth, Percival Street, Clerkenwell, London—and you can send your diamond to them with the knowledge that you are sending it to those who thoroughly understand their business.—E. D.

**Electric Swindlers.**—G. T. (*Hollinwood*).—I do not know the firm of traders mentioned by you in your letter other than by name. I have seen their advertisements in the papers, but these have appeared to me to be too tempting to be those of respectable tradesmen, so have not been caught with their bait. A whole batch of them sprang up like mushrooms a few months since, and changed their names every few weeks, but the trick was soon detected and exposed. When electrical instruments are advertised at ridiculously low prices, attended by absurdly high claims of efficiency, you may well expect the whole to be a swindle, and the advertisers a gang of electric swindlers. Such scoundrels ruin legitimate trade by destroying public confidence, which is the very soul of trade. When men order goods and do not pay for them, or take money for goods they do not supply, or in any other way obtain goods or money under false pretences, they are thieves, and should be treated as such by all honest men. I should like to see all such swindlers well scorched by public exposure in the newspapers. I should advise you to sue them for the money at once, and in future only deal with men of standing and known character, and who have *bonâ-fide* business premises and addresses.—G. E. B.

**Wooden Mole Traps.**—J. J. (*Cumberland*).—The best plan for J. J. is to make his own traps. This is not a difficult matter to do.

**Tagging Machines.**—F. B. (*Leek*).—You wrote a second time before the information you needed could be obtained and printed.

**Photos on Metal.**—A. W. (*Parsonstown*).—Yes, plates are specially prepared for photo zinco work, but only so far as the flatness and substance of them go. Most have secret methods of working, so very much depending on skill rather than formula. A method frequently used to print an image on

bichromated gelatine: Swill it with water, ink with a greasy ink, and transfer to zinc; or transfer an image, and etch the zine with an acid solution. Either plan requires considerable practice to obtain good results.—D.

**Ironmonger's Spare Time.**—EVENING.—The best way that I can suggest for an ironmonger's assistant to utilise spare time in evenings, etc., is to study some of the practical branches of the trade. By practical, I mean the working departments. Take, for, instance, electrical work. In the present day an ironmonger who does not go in for elcctric bell work is bebind the times; and yet I venture to say that very few know anything about the practical making or fitting up. This is one thing that I am sure will well repay your time and trouble, if not immediately, in days to come, when you may perhaps be a master, and have men under you; and even if this is not to be your fortune, you will be all the more valued as an assistant. You should fit yonrself up a little work-bench, provide yourself with the necessary tools, and take for your instructions the valuable articles written in WORK by Mr. G. E. Bonney. I call them valuable becausc, being a practical man myself, I can appreciate their thoroughness and correctness; and I venture to say that if you thoroughly go into them, and carry out the details of electric bell making and fitting, you will create in yourself such an interest that you will seek to go farther into the fascinating paths of electricity. If you have any workmen on the firm in which you are employed, they would, no doubt, assist you in any technical details that you might find difficult. If you persevere, you will soon find it remunerative. I have in my mind a young man in exactly a similar position to yourself who studied tbe subject I have recommended to you, who is making a fair sum doing this kind of work for his employers: sometimes by himself, sometimes assisting the workmen. There is no reason why you should not do the same if you persevere.—R. A.

**Periscopic Glasses.**—H. G. H. (*Sheffield*).—The combination alluded to will have the qualities claimed for them. Tbc probability, however, of anyone unacquainted with the properties of lenses is that the combination would not work satisfactorily. Non-corrected lenses, such as thosc alluded to, if combined, would require very long exposures, as of neeessity the working aperture is very small. The best method is to use only two lenses, *close together*. The combined foci would be about half that of the shortest focus lens, whatever lenses were used; for instance: a 24 in. combined with a 12 in. would produce a focus of about 6 in. Of course, this is not exact, but suffieiently so for all practical purposes. Suppose another similar lens was added to this pair, the focus would be reduced to about 3 in. As spectacle lenses can be purchased of any focus, varying about two inches, as 20, 22, 24, and so on, for the camera mentioned one of 20 in. focus and one of 14 in., with the 20 in. outside, would form a good combination and give a nice-sized image. If this focal length was not approved, using a lens say 10 or 12 in. instead of the 14 in. would reduce the size of the image without the intervention of any other lens to alter the focus. The fewer the lenses the better the results. Get one of the photographie journals of about a year ago, in which a paper on the subject by Mr. Lyonel Clarke, read before the Camera Club, was published. The experiments made by him and recorded in that paper will supply very much useful information of the kind desired that the space at disposal in these columns is inadequate to give in detail. It must always be remembered that the spectacle lens, being uncorrected, cannot be treated satisfaetorily in the same manner as properly cemented and corrected ones. It is an *inexpensive* method of making a *practicable* instrument, and one that will do *really* good work; but at the same time it must not be expected to have all the good qualities of an orthodox first-class lens.—D.

**Binding WORK.**—F. C. S. (*Manchester*).—The London price for binding the yearly volume in the cloth eover is 2s. 9d., but the carriage to and from London would, of course, be additional.

**Switchback Railway.**—SIGNARF TSEW.—You do not say how long the railway is to be, nor how many passengers the carriage is to contain—in fact, you give no data at all upon whieh to work, so I can only give you a few general instructions. The difference in height between any summit and the one next after it should bc at least one-hundredth of the length of rails laid between these summits, and if your carriage does not run very easily this difference may be insufficient to carry it over. At each summit you may make the rails in a short circular arc convex upwards, and these ares are to be joined by cireular arcs convex downwards. The depth of descent does not signify so loug as the difference of summit heights is determined in proportion to the *length of rail* (not horizontal distance between summits). Your track may be carried on timbers about 4 in. square on braced trestles of the same scantling, placed about 10 ft. apart. On the horizontal timbers—which are to be cross-strutted together—are spiked down railway bars of the lightest section you can get. Vignolle's section is very eonvenient: it is single-headed, with flat bottom, and held down by hook bolts. There is nothing special about the earriage: it may be made like an ordinary open tramcar, with cross or garden seats. You must be careful that tbe rails meet accurately at the joints, and that tbeir surfaces form an even and *continuous* curve; otherwise there will be danger of the carriage running off. At the end of the track toothed racks are laid for some distance beside each rail, and into these fall hanging pawls pivoted under the carriage, to prevent its running back after coming to rest. The end of the track should for safety be carried very nearly up to the level of the starting-point, to prevent an over-run.—F. C.

**Model Ship.**—J. C. (*Bristol*).—Find, by trial, the point in the ship's length at which it balances as nearly as is practicable, and beneath this point fix a vertical bar—flat will be the most convenient—and support it upon an axis close nnder the ship. To the lower end of the vertical bar, which may be any eonvenient length, fix a weight, such as a lead disc, just sufficient to hold the ship upright. Get a clock movement—second-hand will do—take out the escapement, and fix a crank, say 1 in. throw, on the arbor of the minute hand. Connect the pin of the crank by a rod, with the vertical bar under the ship, at such a distance below the pin on which it hangs as will give the required pitch. The best way to do this will be to fit a tightly-sliding block upon the vertical rod, and on the block fix a pin to take one end of the connecting-rod from the crank, then this block can be slid up or down until the required movement is obtained. A light spring should be fixed to the case, with a screw behind to press it against the crank arbor, to regulate tbe speed of the movement. The sea may be represented by glazed green "lining" (sold by drapers), and should be glued round the sides of the ship and round those of the case, being left loose and crinkly, to represent the rise and fall of the waves. Your ship would look better if you made it to roll as well as pitch. To do this you would have to carry the vertical bar (which would then be round) in a ball and socket joint instead of on a pin, and let its lower end rest in a hole in a horizontal wheel, carried, instead of a crank, by the clock movement. The mechanism must be carried by cross-pieces to leave the bottom free, which must be put on last, after the "sea" has been glued in.—F. C.

**French and German Accents.**—W. A. (*Beckenham*).—If the dictionaries you refer to do not supply what you want, no other books oceur to our mind.

**Van Wheels.**—W. B. (*Kent*).—I am engaged at present in writing on wheel-making. In the meantime, until the subject appears, you must read carefully a former answer of mine to a queriston wheelmaking in "Shop," No. 66, Vol. II., page 225. The nave or hub of a van wheel will have to be turned "coach fashion," and not "cart fashion." The illustration in No. 66 for hand-cart wheel is turned cart fashion; it will also be better and eheaper for you to buy the spokes ready dressed and tenoned. Yes, you will have to use a templet or felloe pattern to work by. To ascertain the length of felloes for a wheel, however large or small, we describe a eircle ½ in. higher than the height of the wheel. We next describe an inner circle, 2 in. or 2½ in. (whatever the thickness of the felloes or rim may be) distant from the outer circle. If there are to be sixteen spokes in the wheel, we divide the circle into eight equal divisions or parts, each part representing a felloe. If there are fonrteen spokes, we divide into seven parts, etc., two spokes to each felloe. A piece of wood should be fixed so that one of these parts is described upon it when dividing the eircle into parts; each part must bo of equal length, or the felloe joint would have the wrong bevel: a most important point in wheeling. Whien the pattern is sawn out, the size of the wheel should be painted upon it, to show at a glance what height the wheel would be if seven or eight of these were placed in a circle. Use an ordinary carpenter's hand saw for jointing, the felloes being sawn out with the band saw.—W.P.

**Mole Traps.**—E. M. (*Rainham*).—Thanks for your answer, whieh you will have seen has been anticipated. That "star of the first magnitude" whieh you allege you saw "on the ground" at midnight might suit some scientifie paper rather than WORK. We deal with hard facts.—ED.

**Gas, Petroleum, and Wind Motor.**—C. T. A. (*London, N.*)—The question whether you can make a petroleum engine is difficult to answer. There are two in the market: Priestman's (Messrs. Priestman Bros., Holderness Foundry, Hull) and Knight's (J. H. Knight, Barfield, Farnham). A quarter horse-power petroleum engine would cost about £30, much the same as a gas engine. If you tried to make one, you would, of course, have to study the patents, so as to avoid infringing them. Another plan would be to use a gas engine, and let it draw its charge through one of Fletcher's gas generators, which is simply a box filled with cotton wicks dropping into petroleum; air drawn through the box comes out an explosive mixture. Write to Thomas Fletcher, gas engineer, Warrington, and ask if he makes gas generators for that purpose. Perhaps the Robinson hot-air engine would suit you. It will require less attention, and be more easy to manage than a petroleum engine, and have no bad smell. Now, as to the wind motor. This might be managed if you live in a windy situation, and if you employ some means to store up power for use when the wind does not blow. Here lies the difficulty. Windmills can be used to pump water, which is stored up till wanted; they are just the things for that, because they can pump a little more whenever the wind blows: but for a lathe or dynamo you must have some way to store up the wind power, since you may be a day or two without any at all; this can be done by electrical accumulators or secondary batteries, or by using the wind power to force air into a receiver for compressed air, which air you would use to drive an engine exactly like a steam engine. You see, the whole thing becomes rather complicated. No. 94, Vol. II., contains an article on "Small Dynamos for Electric Lighting." Consult the advertisements in WORK.—F. A. M.

**Steel Spike Hook.**—A SUBSCRIBER.—I should try a local gas-fitter or an ornamental smith. They would procure the castings and supply and fit up the other parts.—J.

**Wages.**—APPRENTICE.—There is no fixed rule for the rate of wages payable to a cabinet-maker's apprentice, as so much depends upon the class of trade done and the amount of premium paid. If you are properly "bound," your best way is to endeavour to make yourself master of your trade; you will then be in a much better position to estimate your proper value and ask accordingly.—E. D.

**Perpetual Motion.**—H. D. S. (*Uxbridge*).—You are probably right when you premise that your invention for securing perpetual motion may not gain the end you desire. A good many minds for a good many years have been engaged upon the same matter, but hitherto without success. This need not, however, prevent you from submitting your model to us, and most assuredly it shall be kept strictly private.—ED.

**Frosty Windows.**—SCULPTOR.—When the moisture suspended in the comparatively warm air of your shop comes in eontact with the glass, which is of much the same temperature as the freezing air outside, it is of course condensed and frozen into ice. You might generally avoid this and the other inconveniences of which you complain, as well as greatly increase the warmth and comfort of your workroom, by having double windows—two thicknesses of glass. Between these you would have a space filled with temperate air, and thus keep the frost at arm's length, so to speak, from the glass with which the air of your room comes in contact. This is the plan adopted in northern countries. Yet surely, with ordinary windows, you can place a cloth, or something else which will suck up the moisture from the melting frost flowers, at the bottom of the glass to prevent it from running down your walls.—M. M.

**Cleaning Monuments in Stone and Marble.**—SCULPTOR.—We are not aware that there is any way of removing lichen, etc., from soft stone without labour. Acids would rot the surface, and potash should be used with caution. But for preventing such growths we imagine that a solution of silica (the "water-gloss" of the mural painters) might well be employed. It would harden and protect the surface without in any way clogging or disfiguring it. We are under the impression that it has been successfully used, but have not ourselves tried it; but we are well acquainted with stones which develop a natural coat of silica by exposure and preserve their sharpness and cleanness in consequence. As regards removing stains from Sicilian marble, information on the subject will be found in Vol. II., on pp. 406, 437, 458, (Nos. 77, 78, 80), and elsewhere in WORK. If potash, salt of lemons, or soaking in wet sand fail to remove such discolorations, we cannot say what will fetch them out. Some stains are so obdurate that no ordinary remedy seems to touch them, and any reader who has had special experience in this direction would do good service by enlightening his fellow-workers.—M. M.

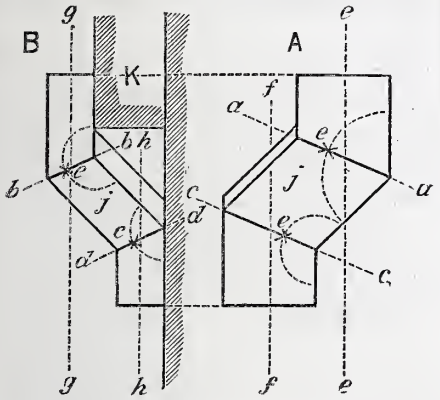
**Brazing.**—L. W. (*Islington*).—For information on brazing, see Nos. 36, 42, 48, 50, 65, 76, and 92 of WORK.

**Re-setting Glazier's Diamond.**—SPARK.—A similar query to yours is answered on p. 224, No. 67, Vol. II. of WORK. From the particulars there given, you will be able to judge if you can do it yourself. The best plan in most cases is to send it to some such firm as Sharratt & Newth, 44, Percival Street, Clerkenwell, London, E.C., or any other maker of glazier's diamonds.—H. S. G.

**Scotch Bagpipe.**—LOVER OF MUSIC.—The Scoteh bagpipe is composed of a sheepskin bag, covered with baize, tartan, or some similar material, whieh forms the wind chamber. The skin is kept soft and flexible by a piece of fat whieh is always kept inside. The chanter tube is bored with seven finger-holes in front and one behind for the thumb of the left hand, and this tube and the three drones are tied into the wind-bag in such a way that no air can escape. Then there is the mouthpiece tube. All these tubes are, of course, wood, and are mounted in silver or ivory, according to price. We should, however, advise our correspondent not to attempt the making of a set of bagpipes throughout, and we therefore give him the name of a firm of pipe-makers, who will perhaps supply him with the detached parts of proper proportion. The sounds which can be obtained from a properly made pair of bagpipes are so fearful and wonderful that one shudders at the idea of the awful possibilities of an amateur production. The name of the firm is John Center, Morrison Street, Edinburgh.—G.

**Rain-Water Pipe.**—J. G. (*Glasgow*).—A correspondent, J. G., asked some time since for information how to get the shape of a pipe coming down over a plinth. The Editor himself, in the absence of clear information on the part of the querist, supposed a plain zine pipe was intended, and gave information as to the projection of the sheets. J. G. now explained that a cast-iron pipe was meant, and the Editor, knowing this was in my line, passed the question on to me. I took a pipe of the form I thought was wanted, set it out in one plane, and showed on p. 381, Vol. III., how the bevels could

be obtained. J. G. sends at length a model of a pipe set out in *two* planes, of which the accompanying figure is a drawing, made to scale, and asks how to get at the bevels for the joints of the pattern. I sent back a reply, printed on p. 573. Now comes an impertinent letter from J. G., saying:—"Sir,—This, the commonest and simplest of jobs, has evidently baffled J. to demonstrate what was wanted. He (J.) says, 'Draw out the pipe in elevation and in front view, bisecting the angles.' Great Euclid! what does it mean? We strongly suspect the *studium inane* of Darwin. We earnestly hope you will not allow this to slip without a demonstration." As a final reply, I insert this sketch in WORK for the verdict of my pattern-making friends. J. G. has sent a model of a pipe of which he has actually got the bevel, and then asks how he is to get it! Although so ludicrously simple, I must needs go now into trivial details. Thus, at A there is a front elevation, at B a side elevation of the pipe in question. It is therefore set out in two planes—that is, in both front and side views. J. G. wants to get the angles of *a a*, *b b*, *c c*, and *d d*. I said, and say still, set out the pipe on a drawing-board, and bisect the angles formed by the pipe body, and cut the pattern accordingly. Thus, the centres, *e e*, *f f*, are the



Rain-Water Pipe.

centres of the pipe in front view; *g g*, *h h* are the centres in side view. Set these out to full size or to scale, and the outline of the pipe also. Draw in the sloping part, *j*, in any convenient diagonal position to clear the plinth, K. Then bisect the angles formed by the pipe outlines, as at *e*, *e*, *e*, *e*, and draw lines *a a*, *b b*, etc. The lines *a a*, *b b* will give one joint face, the lines *c c*, *d d* will give the other, which, if worked to with saw and plane, will ensure the pipe being of the shape required to clear the plinth. Without commenting on the insolence of J. G., to whom I shall not reply again, I ask the readers of WORK if they know of any more ready and practical way of getting at the angles in the Fig. The query was sent to me because I am familiar with pattern and foundry work. I have made, and have given instructions for making, hundreds of jobbing pipes of all kinds, and I have described just the way in which I should set about it, with the certainty of making a correct job. Even the gods must fight in vain against stupidity; and if J. G. is unable to understand this description, I cannot make it clearer; or, if he wants some more elaborate and roundabout way of doing the simplest possible job, then I ask, *cui bono?*—J.

**Writing-Desk.**—G. J. W. (*Ballymena*).—It is a pleasure to reply to such an explicitly placed query

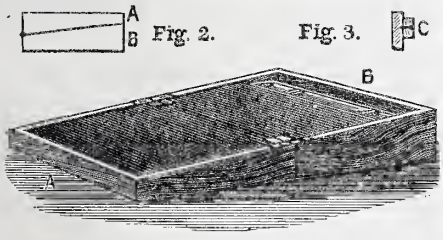


Fig. 1.

Writing-Desk. Fig. 1.—Desk open. Fig. 2.—End View of Desk when closed (drawn to a smaller scale). Fig. 3.—Section of Screwed Piece against Ink-Pot Spaces to form a Rebate for Lid.

as yours. One comprehends instantly the correct requirements. The desk, of which a sketch is here subjoined, is undoubtedly the one you are in search of. The back and front sides, respectively A and B in Fig 1, contact with each other when the desk is closed, as in Fig. 2. It is essential that the *hinged* sides each coincide exactly in depth, to permit of proper adjustment. According to an old article of the kind I have in my possession, the depth of A should be about 1 in., that of B 3 in., while the intervening divided sides (Fig. 1) should each be about 2 in., thus making a uniform depth, when the desk is closed, of 4 in. Your proposed length of 20 in. (when open of course) is suitable. A proportionate width will be 12 in. Two thin lids are bound to each other by means of the fabric covering them, a width of fabric intervening between the united edges equal to two thicknesses (about three-eighths) of the sides. The latter are rebated, where necessary, to allow the lids to lie flush, while they are held permanently in position by means of the fabric being tacked to the hinged sides of the desk. In lieu of a rebate adjacent to the shallow ink spaces, a small strip (C, Fig. 3) could be screwed. Space forbids more remarks, excepting to say that the hinges are screwed to the narrow side edges.—J. S.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Ornamental Brass Castings.**—J. P. (*Accrington*) writes:—"Will any reader of WORK give me the address of a firm where ornamental brass castings, such as horses, dogs, clowns, etc., may be had?"

**Carboline or Carbolinum.**—WICKER would be glad to be informed where this is obtainable in London.

**Lucrative Home Industry.**—W. M. Q. (*Elgin*) asks if any reader of WORK would kindly inform him of a lucrative home industry. He lives in the country, and could spare a few hours each evening.

**Colours for Diagram.**—A NEW READER writes:—"I have to make some diagrams, coloured. I have tried water-colours, but they are not brilliant, and crayons are liable to smudge. Is there any preparation to cover the crayon with to keep it from smudging, or any other colours I could use more suitable?"

**Vellum.**—F. B. (*Clapham, S.W.*) writes:—"Would anyone kindly mention the name of some firm on the Continent where I could purchase vellum in large quantities, or tell me the best plan to adopt? I am given to understand that I should have to pay double the amount for an inferior article over here."

**Vertical Furnace.**—G. W. (*Bournemouth*) writes:—"I should like some particulars of a vertical furnace (with a sketch, if possible) for heating wheel tires. Some reader, perhaps, may be able to oblige. Should the chimney or shaft be the door end, or *vice versâ?*"

**Quick Varnish.**—J. K. (*Patricroft*) writes:—"Would any reader kindly give through the 'Shop' column a recipe for varnish that will dry quick and bear out with one coat at a small cost? The above is for skipping-rope handles, spinning-tops, and wooden toys—something after the style of a Venetian blind gloss."

**Adhering Composition.**—F. W. (*South Darenth*) writes:—"Could any brother reader of WORK inform me of a composition that will make paper adhere to steel bands which revolve upon two wheels, about two inches in diameter?"

**A Hard and Fast Cement.**—A. R. (*Redcar*) writes:—"I have tried the recipe for the above, given in 'Means, Modes, and Methods' part of WORK on p. 602, and find it is a complete failure. I shall be pleased for some further particulars."

**Water-Wheel for Saw Driving.**—CELL writes:—"I should like to know, through 'Shop,' the way to make a water-wheel to work a circular saw 6 in. in diameter."

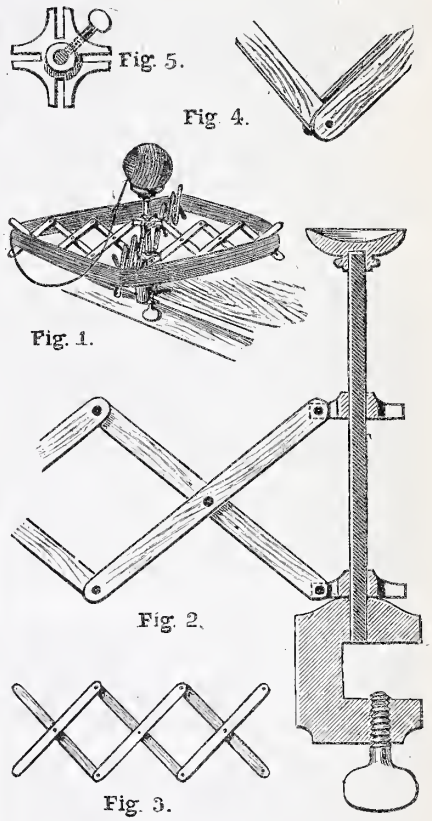
**Cameo Cutting.**—J. A. B. (*Camberwell*) writes to say that "he takes in *Cassell's Family Magazine*, and that he has read a chapter on the art stated above, wherein the writer mentions that the designs are cut out of conch-shell, and also that pieces of the shell are sold besides whole ones; also that special tools are made for carving the designs. Could some of our readers of WORK mention some of the principal firms that supply the material and the tools that are used in carrying out this art?"

**Maguay Electric Lamp.**—W. M. (*Dundee*) (see WORK, No. 142) writes:—"Would W. G. Sherborne let me know where these can be obtained, and probable cost of same?"

**Magnetism.**—BEGINNER writes:—"I want to magnetise several bars of steel, 5½ in. long, for experimental purposes. Will some reader tell me the best way to do them? I am anxious to make the necessary apparatus."

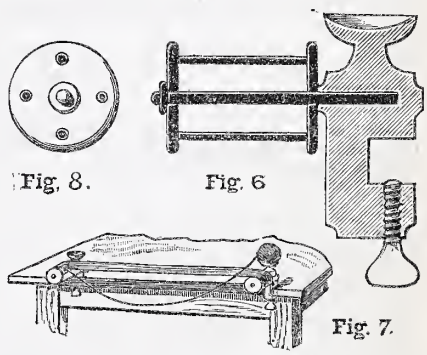
## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Wool-Winders.**—A. M. (*Glasgow*) writes, in reply to MART (see p. 621, No. 143):—"In response to the request of a correspondent for a design and some details of construction of a wool-winder, I enclose two designs of this article which I have seen in use. The first (illustrated in Figs 1, 2, 3, 4, and 5) consists of four lattice-work arms fixed to a central stand, the whole revolving while the wool is being wound. In Fig. 1 is given a general view of the article in use, the ball being for a moment placed in the cup. Fig. 2 shows a section through the centre of the article, and as it is drawn half full size, all the various sizes, etc., can be easily obtained. The lowermost portion is for fixing the apparatus to the edge of a table. It is in the form of a cramp, the screw underneath working fast against the under side of the table top. In this portion all the rest of the apparatus revolves. Notice the centre pillar entering into this part in Fig. 2; it must not be made at all tight, as it must revolve freely. This pillar carries the four expanding arms, which are connected with it by means of a pair of collars or rings, and above all is the cup for receiving the ball of wool at any time the individual winding may want both hands free. A smaller sketch of the lattice-work arm is given in Fig. 3; every alternate bar is, for the sake of strength, made double, the single bar being placed between the two portions of the double bar, and riveted as in sketch (Fig. 4). The four arms are connected by means of a pair of collars, as shown in Figs. 2 and 5, the latter Fig. being a top view of the collar. The arms are inserted in the slots prepared for them, and are fastened with a pin. The lower collar is fixed to the pillar, but the upper one is left free to slide up



Wool-Winder and Parts.

and down the pillar, as the arms are contracted or expanded, to suit the wool. To keep the arms fixed at any particular size, a screw pin is inserted in one side of the top collar to screw against the pillar (see Fig. 5). As lightness is an essential in the construction of the revolving portion of this article, the wood should be kept thin, and therefore should be made of birch or such tough stuff. The other design, of which a general view is given in Fig. 6, consists of a pair of large reels fixed to the edge of



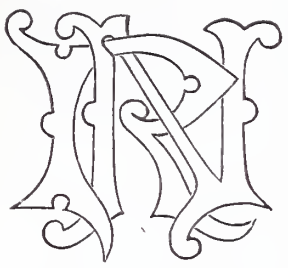
Wool-Winder and Parts.

a table, at a suitable distance apart. The wool is put over the two reels, and wound from them. An enlarged drawing of these and of their necessary fastenings to the table-edge is given in Fig. 7, drawn half full size. The recess for the table top and the screw for pinching it and keeping all tight are there shown, while further up is seen the cup in which the ball may be at any time placed. The spindle on which the reel revolves is inserted on one side and made fast, and the reel itself is shown in end view in Fig. 8. It has four bars or rods across from end to end. This design is undoubtedly a stronger one than the former, though it does not

seem so compact. Each has its own advantages, and both perform their duties in a satisfactory manner, and that is in itself no mean recommendation."

**Saw Bench.**—CHOPSTICK writes, in reply to WOOD-WORKER (see p. 622, No. 143):—"I beg to inform him and others that before these lines appear in print an article on a saw bench to work by hand will be in the Editor's hands, and he will most likely publish it at his convenience. It will be a practical tool, and will cut timber up to three inches thick, as I have done myself on a similar home-made bench."

**Monogram for Fretwork.**—R. D. T. (*Marylebone, W.*) writes (see p. 590, No. 141):—"I notice in 'Shop' that N. R. (*Yeovil*) asks for a monogram for fretwork. I have made a sketch of one which I think would perhaps do, and hope N. R. will like it."



Monogram for Fretwork.

**Photography.**—D. C. (*Marsden*) writes, in reply to C. E. H. (*Horwich*):—"I may say I know a little about the process of colouring photos by the transparleum method, that being the word our correspondent had forgotten. The address from which I obtained my outfit of material necessary to make transparleum pictures was the Continental Novelty Company, but I cannot vouch for the existence of the company now. About two years ago I wrote to the address, asking them to forward me more materials. About a week after I received my letter back from the Dead Letter Office, saying that they could not find the company with the address given; so that they must either have changed address or else have given up the business. For my part, I cannot see the slightest difference between the crystoleum and the transparleum method of painting or colouring photos. I have read the articles which have appeared in Vol. I. of WORK on the crystoleum method of colouring photos, and I think it is exactly like the transparleum process in every detail."

**Besoms.**—TRIPLE EXPANSION writes, in sequence to BESOM MAKER and J. W. H. (see WORK, p. 635, No. 144):—"Worcestershire is well stocked with gipsies, and I will try to find one that makes besoms. Besom-making is a trade carried on in Bewdley, three miles from here (Kidderminster), and Richard Ashcroft, of Bark Hill, Bewdley, is a good maker."

**Skates.**—L. L. H. (*Falmouth*) writes, in reply to JACK FROST (see p. 637, No. 144):—"I strongly advise you not to attempt to grind your own skates; you would almost surely spoil them. They should be ground across the stone, and it is a job that requires much practice."

**Photography versus Painting.**—H. E. (*S. Norwood*) writes, in reply to A. B. (*Glasgow*) (see p. 686, No. 147):—"Without seeing your painting it is impossible to say why you cannot obtain a copy. Have you tried isochromatic plates? These are the only ones to render colours correctly. Possibly your painting may be yellow with age. If so, ordinary plates would not be of much use. As you say several experienced men have had a try, I do not know what to advise. Perhaps the Mahatmas are having a game with it. If you think it worth your while to send the picture on to me, I will see what I can do. I have had some little experience in copying."

**Early Riser's Friend.**—H. E. (*S. Norwood*) writes, in reply to WILL (see p. 686, No. 147):—"If you write to Stevens & Son, of Whitecross Place, Wilson Street, E.C., sending them a copy of the article in question, they will make you all the fittings at a reasonable rate. Their workmanship is A1, and price moderate."

**Fret Saw.**—J. W. B. (*Huddersfield*) writes, in answer to W. M. (*Brixton Hill*) (see p. 651, No. 145), "that Barnes' improved fret saws are used by fret-cutters and carvers, and equal steam-power."

**Pins.**—M. (*Bishop Auckland*) writes, in reply to A. W. B. (*Bristol*) (see p. 622, No. 143):—"Send 6d. to Kirby Beard & Co., Bradford Street, Birmingham, for their sample card and description of pin-making, which will give you all particulars."

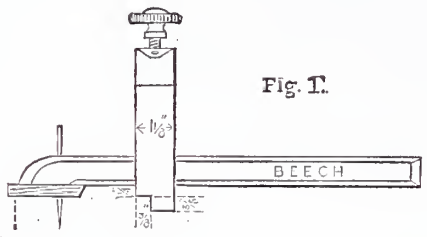
**Pottery and Porcelain.**—M. (*Bishop Auckland*) writes, in reply to T. H. L. (*Dublin*) (see p. 606, No. 142):—"One of the following will suit you: Chaffers' 'Collectors' Handbook of Marks and Monograms,' price 5s.; or Chaffers' 'Marks and Monograms,' price 32s. (Batsford, of High Holborn)."

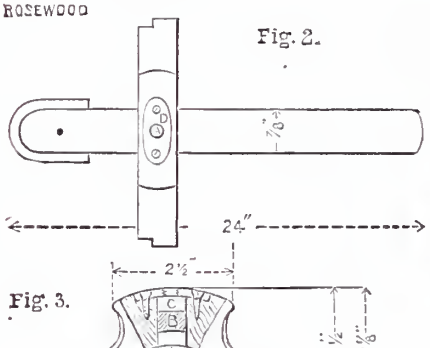
**Water Motor.**—M. (*Bishop Auckland*) writes, in reply to WATER MOTOR (see p. 606, No. 142):—"The Editor has a drawing and description of a water motor, which will be published as soon as space can be found, which I think will suit you. All particulars are given with it. Should any part not be sufficiently clear to you, if you write again I will give you any further particulars."

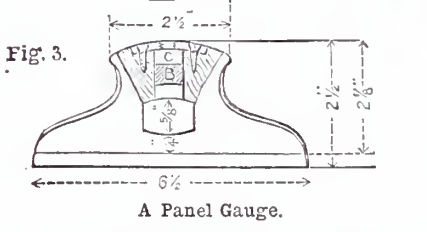
**Model Yacht Fittings.**—M. (*Bishop Auckland*) writes, in reply to T. H. L. (*Newport, Mon.*) (see p. 622, No. 142):—"You can get fittings for model yachts from Mr. Lee, who advertises in WORK; or if you want to make them, if you say what you require I will send you a sketch. I have made my own fittings for a cutter 3 ft. long."

**Fretwork.**—N. T. LEE (17, *Home Road, Battersea, London, S.W.*) writes to W. M. (*Brixton Hill*) (see p. 654, No. 145):—"If W.M. will take the trouble of calling at above address (not very far from his home), I will show him a machine (a Dexter) which I have had in constant use for the past seven years, and which looks like lasting for the next seven years. I will also show him work done by it up to one inch thick, and down to 'cigar boxes.' I have seen many machines such as he describes 'useless.' Let him write me the time he intends calling, so that I can be 'at home,' as I may be able to give him a few other 'useful hints,' which I will willingly do. I am the winner of the first prize in Group I., Division A, Class 3, and also special prize for best exhibit taken from WORK in 'Work' Exhibition.' The Dexter machine is sold in two sizes, I think, A and B, by Messrs. Churchill, Finsbury Square. I will have great pleasure in showing the machine to any reader of our valuable WORK who may give me a call."

**A Panel Gauge.**—EDDIFRA writes, in answer to APPRENTICE (see p. 606, No. 142):—"A panel gauge made to the following dimensions makes a very handy gauge for gauging up to 18 inches. It looks well made of beech, with rosewood tip; it is fixed







A Panel Gauge.

by means of a thumbscrew or milled screw, which presses a piece of boxwood, ⅜ in. square, on the shaft. In the sketch, D is a small iron plate, A is a ¼ in. tapped hole for milled-headed screw, B is the piece of boxwood, and C is the square hole in which it works."

**Dexter Fret Machine.**—M. (*Bishop Auckland*) writes, in reply to E. W. (*Cupar, Fife*) (see p. 686, No. 147):—"The makers of this machine are J. H. Skinner & Co., who advertise in WORK."

**Fretwork.**—M. (*Bishop Auckland*) writes, in reply to W. M. (*Brixton Hill*) (see p. 654, No. 145):—"If you procure the catalogues of J. H. Skinner and Co., Harger Bros., or the Britannia Co., all of whom advertise in WORK, you will find drawings of some very good treadle machines. The advantage of these is that they leave both hands at liberty; although some fretworkers prefer the hand-saw."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. H. C. (*Homerton*); SIGNALMAN; KODAK; W. L. K. ## ART WORK EXHIBITION.

THE Secretary writes:—"This will be held in connection with the Building Exhibition, 1892, to take place at the Royal Agricultural Hall, London, N., March 14th, 15th, 16th, 17th, 18th, 19th, 21st, 22nd, 23rd, 24th, 25th, and 26th.

"There will be eight Groups—viz: (1) Carpentry; (2) Carving; (3) Furniture; (4) Painting and Decorating; (5) Metal Work; (6) Building Appliances and Materials; (7) Building Facilitators; (8) Invention and Design.

"These Groups will consist of three Classes in each Group—viz: (1) Workmen; (2) Apprentices; (3) Amateurs; to be judged from their respective standpoints.

"Applications must be received by February 14th, at latest.

"The Best Exhibit in the Art Work Branch of the Exhibition will have a Gold Medal awarded. The Best Exhibit in each Group will be awarded a Silver Medal; and the Best Exhibit in each Class of each Group will obtain a Bronze Medal, all to be accompanied by First, Second, or Third Class Certificates respectively.

"The Second Best Exhibit in the whole of the Art Work Branch will receive a Silver Medal, One Guinea, and First Class Certificate; the Third Best securing a Bronze Medal and Second Class Certificate.

"The Second Best Exhibit in each of the eight Groups will receive a Bronze Medal and Second Class Certificate.

"The Second Best Exhibit in each Class of each Group will be rewarded with a Third Class Certificate."

The Secretary and Manager is Mr. John Black, 2, Newcastle Street, Strand, W.C.

## WORTH OF FRETWORK DESIGNS.

J. H. SKINNER & CO. have now ready for delivery 8,000 of their Tenth Annual Catalogue of Fretwork, Carving, and Photographic Apparatus, including Designs, Fancy Woods, Treadle and Hand Machines, Frames, Saws, Drills, Planes, Carving Tools, Bevelled-edge Mirrors, Ornaments, Fasteners, and all other requisites; also Swiss and Chinese Wood Carvings, Magic Lanterns, Skates, Fancy Pocket Knives, and Scissors; Amateur Joiners' Benches and Tools; and their new **CELESTIAL ENAMEL** for decorating wood, glass, metal, earthenware, etc., the best and cheapest enamel in the market, including 54 different coloured specimens of the Enamel itself, beautifully mounted on a handsome recessed card (this card alone is well worth the amount charged for Catalogue). The above described Catalogue of 60 pages quarto, with 600 illustrations beautifully lithographed, SENT POST FREE ON RECEIPT OF FOUR STAMPS. With each Catalogue we will include, GRATIS, **One Shillingsworth of Fretwork Designs,** selected by us from our stock. As each Catalogue costs us, with postage, only a fraction less than Sixpence, our customers will thus get in value ONE SHILLING AND SIXPENCE FOR FOURPENCE.

The Season being already so far advanced, we have decided to make this extraordinary offer, in order that our Catalogues may be distributed AT ONCE, trusting to the profit on future orders to recoup us for the loss on Catalogue.

**BEGINNER'S OUTFIT,** consisting of 12-in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient Planed Fretwood and Full Instructions, price 2s. 6d., post free. 6 ft. assorted Planed Fretwood, 2s. 6d.; 12 ft., 4s. 3d., post free. Book containing 12 sheets full-size designs, 1s. Good Fretsaws, 1s. 4d. per gross.

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## DESIGN FOR A CHESS TABLE.

BY FLORENCE HUDSON.

This design may be carried out very effectively either in inlaid work, carving, or painting. The best effect would doubtless be obtained by inlaying, such as ebony and ivory, well-contrasted woods, or stone mosaic, in the style of the Torquay work.

But these methods are costly, and moreover require technical knowledge. Whitewood tables are now procurable at all stores and artist's shops, and are most tempting for decoration, and an excellent effect may be obtained by either of the following methods, without any special knowledge and at little expense.

A close-grained, smooth, white wood should be chosen, and two things must be remembered—*i.e.*, not to lose the sharp contrast of light and shade, and that any ornamentation by relief must be below the plane of the table, as represented by the white squares and pattern, otherwise the chessmen will not stand easily. Also great care must be taken in tracing or drawing the pattern, that the squares are true.

*Wood Carving.*—Having gone round outside (that is, on the dark side) all the patterns and lines with a small gouge, the dark ground can be cut down roughly, so as to leave the pattern in slight relief, and the veins in the leaves can be finely cut. The dark parts must be stained, taking care not to encroach on the light parts, and the whole subsequently polished.

*Poker Work*, or burnt-wood engraving, may be substituted very effectively for carving proper. Follow the outlines, and also the veins, with the point. Then the ground may all be dotted closely with the point. This will probably darken the wood sufficiently without staining, but if not, stain and polish as with the carved work.

*Imitation Inlaid Work.*—The following are very simple but most effective ways of producing the effect of inlaid work :—

Having well sized the white wood, and drawn the design, go over all the outlines firmly with Judson's artist's black, which is really a beautiful dark brown. Then put on a mottled brown ground with the same, diluting it with a little turps. When thoroughly dry, re-size (taking care that the brown does not smudge), and either varnish or French polish, which is by far the most lasting and effective way of finishing. Or ebony and ivory may be imitated by painting all the light parts with perfectly smooth, thick, Chinese white, and the dark with ebony black instead of artist's black. Care must be taken in subsequent sizing and varnishing that the white and black do not mingle. It is as well to size each separately. The effect is excellent if carefully done ; or if colour is desired, the colours chosen can be mixed with Chinese white and glazed with pure colour after. When all put on, outline everything with a fine black line (a little gold-size or veloutine mixed with lamp-black to prevent its running), and then size and varnish, or, better, French polish. The fine black line gives quite an inlaid effect.

This design was carried out originally with 1½ in. squares, on a table top of about 19 in. diameter.

Table tops vary so much, that the safest way is to find the largest possible square to be had out of the circle ; and then to arrange the eight squares and lettering to such a scale as will be well within that limit. In other words, when the whole design is drawn, there should be room left for a bevelled edge, or narrow white border, round the edge of the table.

In whatever way the art-worker may elect to carry out the design, the effect, provided always that the execution be good, cannot fail to be satisfactory. But I shall be understood when I add that it goes well-nigh without saying that everything depends on the way in which the work, whether it be inlaying, carving, or painting, is done.

## PRACTICAL PAPERS FOR SMITHS.

BY J. H.

Case Hardening — Case Hardening at the Forge — Box Hardening — Forgings for Model Work—Differences between Model and General Work—Anvil—File—Leaving Parts Solid—Steel better than Wrought Iron for Model Work—Die Forging—Formation of Dies—Quantity of Material Important.

In the first paper of this series I mentioned several subjects on which I proposed to treat. Space is narrowing up, however, and I find that I must perforce omit two or three of these, and discuss the remainder as briefly as possible in this and in the succeeding and final paper. In this I shall touch on (1) case hardening ; (2) model work ; and (3) die forging.

(1) *Case Hardening.*—Case hardening is a method commonly used for rendering the surface of wrought-iron work as hard as tempered steel. The advantages of its employment are that the toughness of the wrought iron is combined with durability of the wearing surfaces as great as that of steel ; and that the first cost of the forgings, and of the cost of their being tooled and finished into shape, is less than the cost of steel forgings. Case hardening is adopted in link-reversing gear for engines, for the eyes and working faces of various levers, for pins or pivots, and so forth. It is performed as follows :—

There are two methods adopted in case hardening—hardening at the forge, and hardening in pots.

*Case Hardening at the Forge.*—To case harden at the forge, get a quantity of yellow prussiate of potash powdered very fine in an iron tray. Heat the work in the clear fire to a red heat. Take up the prussiate powder in a spoon, and strew it thickly over the surface of the forging. If practicable, roll the forging also in the tray of potash. Time must be given to allow the powder to fuse and run freely over the surface, and then the forging is quenched in water to harden it.

If the forging is so light that it loses its heat too quickly, and before the potash has had time to penetrate, then it must be returned to the fire and heated up to the red heat again before plunging it in water.

*Box Hardening.*—But this method is only suitable for small work, and not for articles of large and irregular form. For these, box hardening is resorted to. Boxes of various kinds are employed. For the heaviest work, cast-iron boxes of circular form with cast-iron covers are used. They are of sizes suitable for the work in hand, ranging, say, from about a foot to two feet or two feet six inches in diameter for engineers' work. For small work, tubes of wrought iron or old pulley bosses are used. The process of hardening is as follows :—The bottom of the box is covered with a thick layer of the hardening material. This consists essentially of such nitrogenous and carbonaceous substances as bone dust, leather clippings, hoofs, salt, and charcoal powder. The forgings are made to alternate with the hardening material in the box. If the forgings are heavy, care must be taken to give them good support among the material, so that they shall not become distorted by their own weight while at a red heat. When the box is filled with alternate layers of work and of material, the cover is put on, and luted with fire clay. It is essential that air be thus completely excluded from the box. Then it is placed in a fire, or, preferably, in a reverberatory furnace, for periods ranging from, say, ten to thirty-six hours. The time during which the box is exposed to the heat of the furnace mainly regulates the depth to which the case hardening will enter. The result, however, depends also partly upon the chemical activity of the hardening agents.

This is assisted by the addition of the salt just now mentioned. Finally, the forgings are turned out into cold water, and are thus hardened. The depth to which the case hardening penetrates varies with the conditions named above. It will range from $\frac{1}{64}$ in. to nearly $\frac{1}{8}$ in. But in the same forgings its depths will not be quite uniform. For light articles, of course, a mere film of surface hardening is enough ; for heavy work, the steely casing should penetrate to the maximum amount, or nearly $\frac{1}{8}$ in. There is this to be said : that since hardening distorts the work, the minimum amount of penetration that is consistent with the purpose for which the forgings are required should be imparted to them—$\frac{1}{16}$ in., or a bare $\frac{1}{16}$ in., may be taken as a good average. In almost all instances the process distorts the forgings somewhat, sometimes more, sometimes less ; and the fitter has to correct outlines, not with a file, which of course will not touch case-hardened work, but with an emery buff, or emery paper.

(2) *Forgings for Model Work.*—Forgings for model work are necessarily expensive, for two reasons. In the first place, in order to produce shapely forgings so nearly like the ultimate finished work that only moderate and uniform amounts for machining are afforded, much time must be spent upon them. In the second place, very few smiths care to undertake such work, because it pays them better to do the ordinary work of the forge, and also because a man must be an exceptionally neat workman to turn these out as perfect as they ought to be made. Yet it is work that practised amateurs, with more time than cash at their disposal, can succeed pretty well with, because there is less of high skill than patience wanted, and there are scarcely any of the really difficult operations of forging involved. There are few special tools required, most of the work being done with hammers and files. The cost of material is small, and the principal appliances are a small anvil and a vice.

*Differences between Model and General Work.*—Speaking generally, we may say that there is less of welding and more of drawing down done in forgings for model work than in those of heavy type. The difference in the dimensions of bossed-up ends or forked ends and their shanks or rods is so small relatively, that it is much easier to reduce the latter with the hammer than to weld the former on If, however, the bosses are of considerable thickness, or the forks large, then it is better to weld them on. There is no difficulty in welding small work, provided no time is lost in hammering the parts together immediately on removal from the fire, which can be done upon a small anvil or a block of iron laid upon the side of the forge.

*Anvil.*—For very light work, one of the small combined anvils and vices will be found serviceable. The work can then be transferred rapidly from one to another as occasion requires, without loss of time. One advantage of a small anvil is that the beak is very useful for turning curves, and to form a suitable bedding when fullering down curved necks and shoulders. For these the ordinary fullering tools are too large. The cross panes of the hammers are useful for this operation. With hammers of different sizes, radii of various curvatures can be formed. Neither are flatters used, but all the battering and smoothing that is done is effected with the hand hammer.

*File.*—Owing to the unsuitability of smiths' ordinary finishing tools for purposes of model work, the file has to be used much more largely in this class of work than in ordinary forgings. When the forgings are cooling down to a black heat, a good deal of material can be removed with little effort, and some kind of finish imparted, that it would be difficult to impart by the hammer alone.

*Leaving Parts Solid.*—Again, in small forged work, many parts are left solid that would be punched or fullered, or cut out in large work. The holes in bosses would seldom be punched, but left to be wholly drilled. The forked ends of eccentric rods are left to be slotted or filed out.

*Steel better than Wrought Iron for Model Work.*—When wrought iron is used for model forgings, the same regard must be had to the direction of the grain as in larger forgings. But in all respects steel is preferable as a material for model work to wrought iron. There is, practically, no grain. It does not open out and prove spilly, like the inferior kinds of wrought iron. It is hard, rigid, and strong, an important consideration when light and slender work is in question, and takes a better polish, and is more durable. For these reasons I should always give the preference to steel over iron for light model forgings.

(3) *Die Forging.*—Die forging, or stamping, is adopted in all modern firms doing repetition work. There are numerous parts in nearly all branches of smiths' work that are required precisely alike, and an enormous saving—often as much as 300 or 400 per cent.—is effected over the hand methods by stamping such work, wholly or partially, in dies. Such parts as flat links for pitch chain, flanges for steam and exhaust pipes, some portions of valve gear, ornamental bosses, railing heads, pins, small levers, and a host of similar articles more or less intricate can be readily stamped with proper appliances. Moreover, another great advantage of such stamped work is that it takes the precise form of the die, and its accuracy is such that the very minimum amount for filing, turning, machining, or polishing can be allowed, and that in a perfectly and uniformly precise amount.

*Formation of Dies.*—The dies are usually made either of cast iron or of steel, the larger dies in the former, the smaller in the latter. In the former case, the required impressions are cast out, and afterwards cleaned and smoothed a little with the file; in the latter case, they have to be cut out with drills, chisels, and files. In either case, sufficient metal must be put into the die to enable it to withstand without fracture the concussion of the blows to which it is subjected. Cast dies are, further, frequently bonded with a wrought-iron ring in order to prevent their bursting under the stress of concussion. For this kind of work the sledge is no use. In little country shops, unprovided with power, the Oliver can be used. But generally the drop hammer, steam hammer, or hydraulic press are used for work of this character; and the heavier and more powerful within reasonable limits they are, the better.

The general mode of working off die forgings is as follows:—The formation of the dies themselves must needs vary with the shapes of the forgings. In the plainest work a single bottom die will often suffice. But if the top of a forging is not plain, then the die must be divided, the upper portion being cut to the requisite outline. The top portion must also be attached to the lower in such a way that it will take its proper position in relation to the lower instantly, without any adjustment. This is usually effected by means of iron dowels, two or three dowels being driven tightly into the lower portion of the die, and standing upwards to fit into corresponding holes drilled in the top portion of the die. The dowels are well tapered, and their ends rounded off to give every facility for entering quickly into the holes in the top portion of the die. Sometimes the bottom dies are furnished with long handles for their manipulation. But as frequently, they are lifted about with the hoop tongs, and the top dies only are furnished with handles. When holes have to be punched in the forgings, corresponding holes are usually drilled in top and bottom dies. The top holes are then parallel, and of the same size as the punch which is inserted in them; but the bottom ones are only of the same size where the lower face of the forging lies, being tapered thence downwards to allow the punched discs to fall down freely.

In many cases two sets of dies are requisite to produce an article. One set will form the sides, and another set the top and bottom. Into the details of these and kindred matters I cannot enter, nor into the relative cost of die *versus* hand forging. Of course, dies are expensive, and however desirable from the point of view of accuracy the use of dies may be, there must always, from a commercial point of view, be a balance struck between the cost of a given quantity of forgings done by hand or by means of dies. As a general rule, there must be at least several dozens of an article required to pay the cost of dies.

*Quantity of Material Important.*—In stamped work, the amount of material required for any given forging must be gauged with accuracy. If there is a little excess of metal, there will be thick fins spreading over the edges, which will not only have to be laboriously cut or ground off, but will prevent the dies from meeting, and so cause the forgings to be thicker than they ought to be. If, on the other hand, the metal is short, then the forgings will not come up keen and clean, but will have edges more or less rounding and inaccurate. After two or three tentative attempts have been made, the amount of metal necessary for any given forging should be estimated accurately.

Time is passing on, and the date that brings us to the conclusion and completion of the third volume of WORK is fast approaching. I am warned, therefore, that this series of papers on the work of the forge and smithy must be brought to a close also, as I said at the commencement of this paper. So the space that yet remains at my disposal shall be devoted appropriately and, I trust, usefully, to the arrangements of the smithy.

## SCARF ORNAMENTS.

BY H. S. GOLDSMITH.

### Scarf Pins.

THE methods that jewellers employ to attach ornaments to the necktie or cravat arrange themselves in three classes, two of which are in ordinary use, while the third is nearly forgotten. One of the two is the subject of this paper, the other is the scarf ring. As these latter are still worn to a considerable extent, they deserve a paper to themselves; but for the third—*i.e.*, scarf brooches—a paragraph here will suffice.

*Scarf Brooches* are mostly of the "comet" pattern shown in Fig. 1, and surely it is about time that the beautiful designs and exquisite workmanship often found in these old-fashioned pieces of work were reproduced, or else that the ideas on which our great-grandfathers based their style of scarf—or rather, shirt-frill—ornaments were once more submitted to the public. This will doubtless depend on the fickle decrees of fashion, and if plain cross-over ties should ever be "the thing," then we may expect and hope to see a revival of the manufacture of this class of ornament.

The opportunity for varied patterns that the elongated form of a comet brooch gives, causes one to wonder why they have not reappeared long before this, if only as a contrast to the insignificant, puny, round beads and minute crescents and horseshoes that have been made by the hundred for the last year or two.

In these scarf brooches, although variety of form is one point, still there is another which we might bear in mind nowadays, and that is the attempt at producing a "jewel." This was defined for us by Carlo Guiliam—the modern Cellini, as he is called—in a lecture given at the Society of Arts on the "Art of the Jeweller." He says: "The object of a jeweller will be to produce the largest amount of beauty in the most limited space possible under the circumstances. A piece of goldsmith's work need not necessarily be expensive; it is the style, the design, the form that will give that grace and refinement which will give joy and pleasure to look at it. The very word itself is derived from the Italian word *giojello*, meaning joy, pleasure to the eye."

Such a paragraph as that applies to our trade in every branch, but with regard to scarf brooches especially, one finds that, be they even plain rounds or ovals, even then the maker has not only done the mechanical part excellently, but by the employment of various well-chosen colours both in stones and gold, as well as in contrasting plain and chased surfaces, that he has produced a real "jewel." The stones in these scarf brooches are not restricted to diamonds alone, but rubies, emeralds, and pearls are very often met with.

The one sketched here (Fig. 1) is a very usual pattern: it is intermediate between the collet with a simple bar and the much more elaborate ones that are to be found in the hands of connoisseurs.

*Pin-stems and the Principles that govern their form.*—Pin-stems and the parts that attach them to the pin-head is, then, the principal subject of this paper. But before we enter into details, let us spend a minute or two in thinking over the purposes for which they are made.

The first thing is, doubtless, to give security to the ornament. Now, the consideration of that leads us naturally to the means we ought to adopt to obtain the utmost power

of holding combined with the equally important—and opposite—quality of easy insertion. In different places different methods are used. Length only is thought sufficient by the French people, for their pin-stems average nearly 3 in. in length, and they are but plain pieces of hard gold wire, nicely pointed. We in England, in trying to "make assurance doubly sure," generally make a groove in the stem, like Fig. 3, D; or else use some of the methods to be mentioned later on, such as the addition of spikes or nuts, etc.

In old work, another sort of addition is introduced for the purpose of obtaining greater security, and that is illustrated in Fig. 5. It is, as you see, another and generally smaller pin, connected by means of a fine chain. The custom of chaining scarf pins together is one that has fallen into disuse, notwithstanding that the fine chain and small pin-head add greatly to the appearance of the chief ornament, leading up to and pointing out the larger one rather than detracting from it; just, in fact, as the frame of a picture improves the appearance of the painting.

Sometimes we find that three pins are attached to one another, each one of importance in itself, and, as one would naturally expect, the chain is occasionally made more of an ornament still by being set with stones, or else by having pearls strung along it at intervals.

This seems beyond our immediate purpose, which is the consideration of obtaining security for the ornament as now worn; so, to proceed with the technical details. One has but to call attention to Fig. 12 (A, B, C, D, E, F, G); these are, of course, the most secure of all, for by the addition of a nut or a pin, *after* the scarf pin is adjusted in the scarf, it becomes impossible for it either to ride up or drop out, or even be snatched out by any of the light-fingered fraternity.

*Details of Manufacture.*—We have glanced at the main purpose of pin-stems, now to consider the best way to carry that purpose out.

We must, in the first place, have the pin-stem pointed, for it has to be inserted in a silk scarf, and it must be strong enough to bear forcing in and out of and through several thicknesses of material. On the other hand, it should not be made thicker than is absolutely necessary, else it would make a large hole, and possibly spoil the scarf.

There is yet another consideration to bear in mind, and that is with reference to the pin-head. For the purpose of clearly indicating the last reason, we will suppose (as an extreme case) that a bead is to form the pin-head: one made, say, of delicate wire-work, and quite hollow. Now, if a piece of filigree work such as this were attached to a thick or clumsily-made stem, would not the result be that the bead would be squeezed up by the finger long before the stem could be forced in and through the hard scarves that are now worn?

The guiding principle of making stems is proper proportion—that is, of greater or less thickness, according to the strength or fragility of the head of the pin, or the use it is to be put to. This proportion, *i.e.*, suitability, is one of the points that a good workman would be sure to have in his mind.

In extreme cases it may be advisable to use a steel needle in place of a gold stem, for be the head ever so weak, it has got to act as the means to force the stem in, and we can do nothing else but use it.

Now to make an attempt at describing, as thoroughly as may be, the steps in the manufacture of a simple plain pin-stem, and then from this—the simplest type—we can show, step by step, the alterations from that which are in common use. It is to be hoped that it will be done in such a manner that an apprentice will be able to judge for himself the different advantages, defects, or improvements that such alterations bring in their train.

*French Pin-stems.*—The simplest stem of all is that illustrated in Fig. 2; it is that used in all French work. It is a quite plain piece of pointed wire, made in 18 ct. gold (alloyed all copper), which has necessarily to be drawn down very hard, to get rid of the natural pliability of that quality. This means, as you know, that for the last twenty or more holes in the draw-plate which it has been through it should not have been annealed. Even that is probably too little, and it would have been better to have twisted it and hammered it, and *not* annealed it at all. Experience will only teach that, so we will take it for granted that your wire is to the proper size, straight and hard; the length we have spoken of as being about 3 in. for smooth stems, the thickness size, 17 B.W.G., or 19 Shakespeare flat gauge.

Of the way it is to be attached to the head, more is written later on, so we now have but to consider the point you have to put to it. It should be like Figs. 2 and 3—that is, neither weak or thin, nor blunt and ugly, like Fig. 4, *b*. Pin-stems are pointed this way doubtless as a result of experience, for we find the same shape of point almost exactly in the ordinary pins sold by the drapers. If you will compare these with needles, you will see how the greater hardness, etc., of the metal, steel, permits of a much finer point to the latter.

In the metals—gold and German silver—we cannot obtain such a special hardness, therefore do not make your pin-stems with points like a needle, but condescend to follow the shape given to the humble ordinary pin, which is made of a metal resembling those we use.

This calls to mind that we have of late years had to make up small gold pins, with pearls for heads, to be used to fasten dress ties to the shirt collar. For these also no better model can be found than "short whites" of good quality. Plain stems are occasionally used for the light pins that ladies have to fasten their lace with; the length and strength of stem being made proportionate, of course, to the use they are to be put to, and to the size of the ornament they carry. They will, therefore, be several sizes thinner than the usual stem.

*Twisted Stems.*—From a length of 3 in. we drop to an average length of 2½ in. when the stem is other than plain, such as the general one with a twist, used here in England.

There are two ways to make this form of stem with a hollow, or twist, or groove in it; both ways have their advocates, or at least their users. One way is by filing the groove, the other by hammering and twisting the stem.

The first is thought to be somewhat objectionable, for this reason: that the bottom of the groove is very likely to be not round, but sharp—a continuous nick, as it were. Now, a sharp nick is always the place of greatest weakness, which you can see for yourself if you notice how small a nick, comparatively, an engineer will put in a rod of steel at the place where he wishes to break it.

As we do not want our stems to be always breaking, the second method is preferred by the writer, for he holds that the twisting of the grain of the wire tends towards retaining a good part of the strength which is liable to be lost by having these hollows in a stem.

The steps in making a pin-stem after the second process are drawing the gold wire (9-ct., usually) to a proportionate size—say, 17 B.W.G. size, or the Shakespeare flat gauge, size 19; then to cut it into lengths of about 2½ in., straightening it in the draw-plate before cutting it, of course.

We now have a piece of wire 2½ in. long, straight and hard (Fig. 3, A): this has now to be annealed in the centre, where the twist comes, and nowhere else; then flatten it out with the hammer, like Fig. 3, B, and 3 B′, not with an unequal thickness like Fig. 4, A.

Again anneal it, and proceed to twist it until it comes like Fig. 3, C. This will be done with a couple of hand vices, or in the same way as a brooch tongue is done (see p. 648, Vol. I., of WORK, Fig. 4).

If there is any soldering to be done, it will be the best time to do it now, before the stem is hardened. It may have to be soldered to the head, or a collar may be required; if it is, then let it be a small one—not anything like the great ugly thing on Fig. 4, B.

Now to harden it and finish it. It is soft all over now, except at the point, which you have not been told to anneal, and a good deal of trouble will be saved if you have not annealed it, but have kept it hard. If through inattention or carelessness you have annealed it, then proceed to hammer it first one way, then the other; but do not get it "double"—*i.e.*, split—if you can help it. A pin-stem with a double point ought to be replaced with another one, for soldering the end up means farewell to nearly all hopes of getting a firm, strong point.

If all is right, then hold the stem on a sparrow-hank, small anvil, or smooth iron, and proceed to reduce it to the same diameter all along.

The blows of the hammer are to be many in number, and not heavy, for we have to obtain a gradual and thorough hardening, and to that end the stem must be rotated all the time by the finger and thumb, so that the blows of the hammer will strike successive parts; thus the round section of the wire will be brought back again. This also straightens the stem, so we can proceed to file it up, first roughing the points down, then with a smooth file going over all of it from collar to point; the result should be something like Fig. 3, D. The point, you will notice, is of the same shape as the French one.

*Badly-made Stem.*—As contrasts help to indicate the point of one's argument, Fig. 4, B, is given to be compared in all particulars with Fig. 3. Here follows the chief fault it possesses. It is hammered too thin in the centre of the twist, the wire itself is too thick, the twist is too long and too near the point, and is of course irregular, and finishes off with a kind of gash: then the point is too blunt. That is a too general fault, and yet it could be so easily altered in this and all other cases; but unfortunately it is not. The collar at the top is too large; not that this tends to weakness, but because it is out of proportion to the work it has to do—viz., to act as a stop to tighten the screw against.

*Polishing.*—There are one or two other things that might be said, but we will get

the stem finished off; it only wants polishing. Take a bundle of threads, and charge one single one with crocus and oil; coil it round in the groove and rub away from one end to another; after that, use water of Ayr stone and buffs; don't take it to the lathe and polish off all the corners with a wheel brush: the edge of the groove should be sharp and square, and for a reason apart from the look of the thing. It is a small matter which is generally overlooked, for we know that the object of the twist is to keep the pin steady in the scarf; that being so, no individual will dispute that a hollow with rounding edges is much less likely to catch the silk than one with their square corners.

Do we not twist our stems in the wrong direction, and, in so doing, throw away a considerable amount of holding power? If we twisted our stems as a right-handed screw, and screwed them into the scarf, we should then get plenty of hold: as you can try for yourself when you come across or make a stem with that twist as suggested. I believe the original maker of this kind of pin-stem intended them to be screwed in; but of course people do the things the easiest way, and as a consequence we find that not one in one hundred has its thread to the right. I have written before this about the left-hand screws.

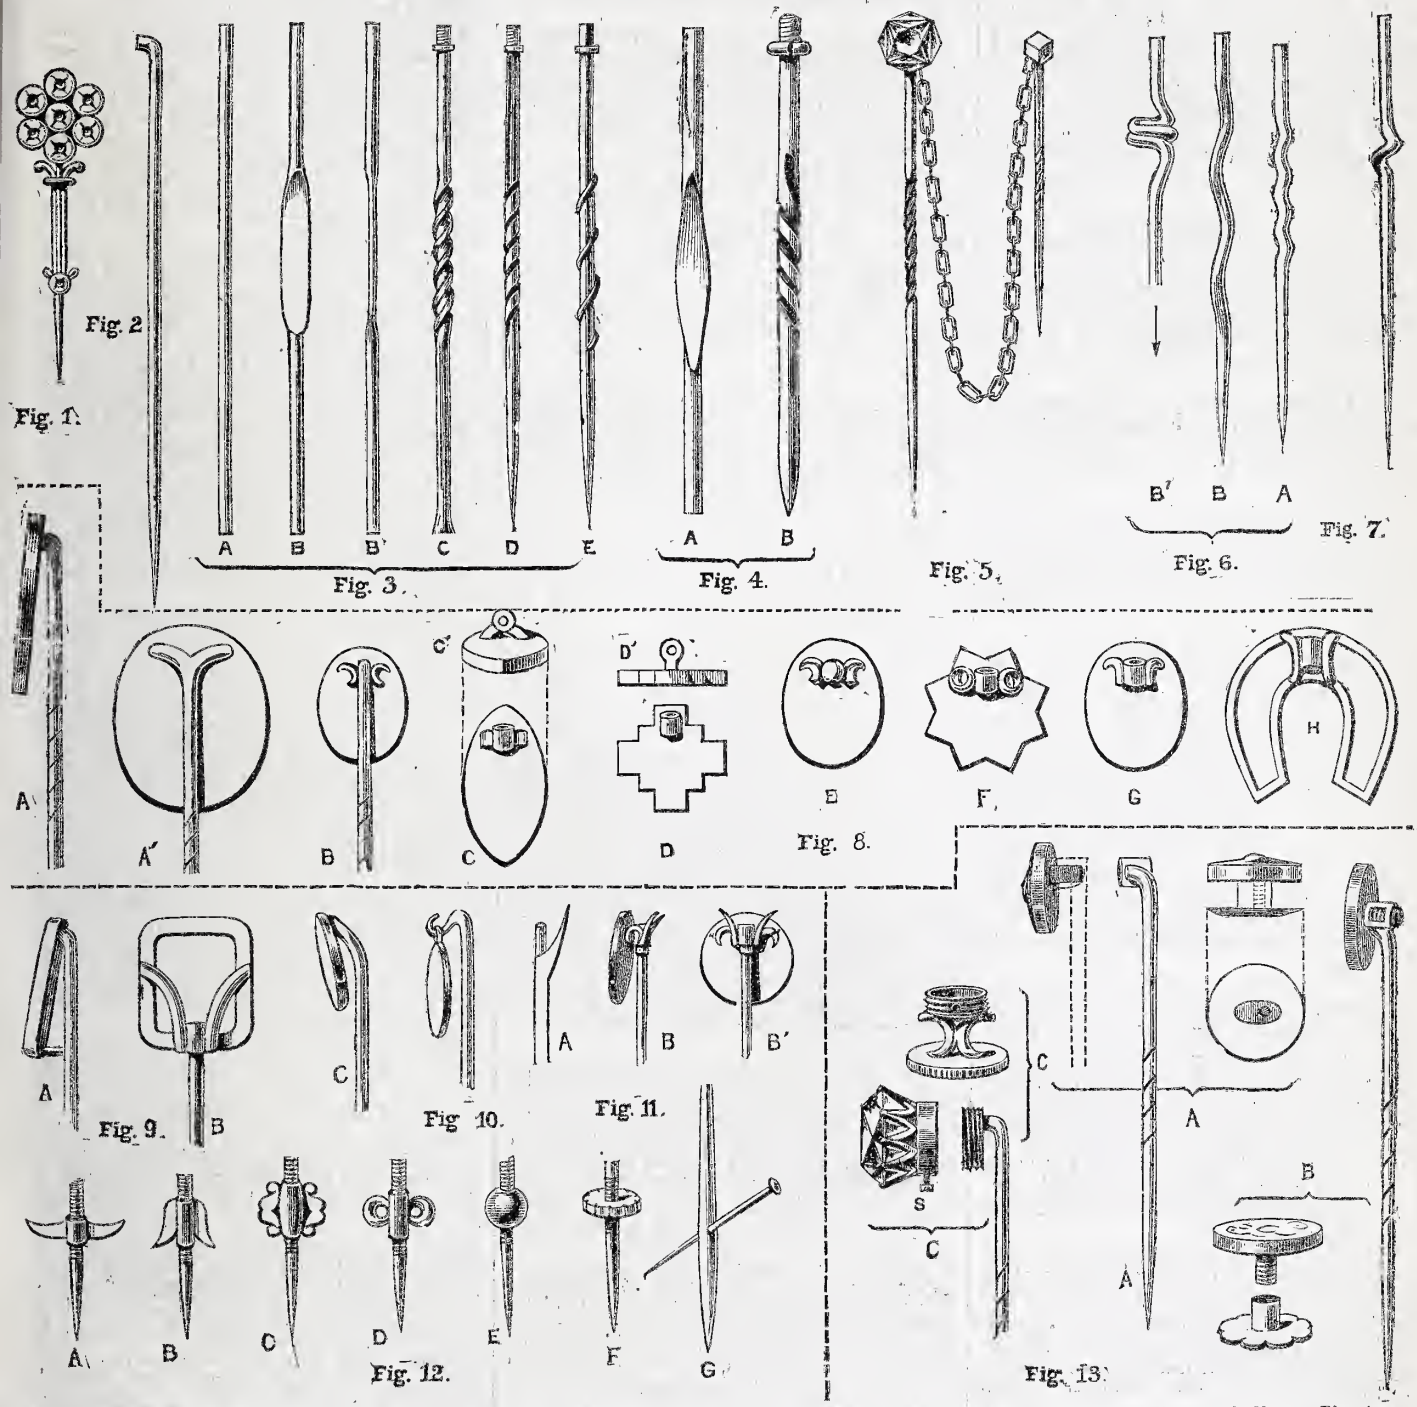

**Fig. 1.**—Comet Brooch, an Old Style of Ornament for Gentleman's Shirt Frill or Cravat. **Fig. 2.**—French Pin-stem. **Fig. 3.**—Ordinary Pin-stem—A, Plain Wire before commencing the Twist; B, the same after Hammering; B', the same after Hammering to show Thickness; C, Appearance after being twisted, and with the Collar soldered on; D, Finished Stem; E, Stem with raised Thread. **Fig. 4.**—A, Wrong way of forging the Stem for twist; B, Shows A when twisted and hammered with bad Style of Point and clumsy appearance generally. **Fig. 5.**—Square Wire Pins connected by Chain for security. **Fig. 6.**—A, Zigzag Stem for Lace Pins; B, Spiral Stem for Lace Pins; B', Mode of commencing Spiral Stem. **Fig. 7.**—Perks and Sons' Screw Stem. **Fig. 8.**—A, To show the amount of Space to be allowed between Pin-head and Stem; A', Back View of same; B, a more Ornamental Form of A, where Stem is soldered direct to the Pin-head; C, D, Back View of a Stirrup or Socket to screw Pin-stem in; C', D', Side View of same; E, F, G, H, Various Forms of Sockets. **Fig. 9.**—A, B, C, Bad Forms of fitting Stems to Pin-heads. **Fig. 10.**—Shepherd's Crook Pin-stem for Swinging Ornaments. **Fig. 11.**—A, Pin-stem with Spike, to prevent Pin riding up in the Scarf; B and B', Side and Back View of similar arrangement, but with two Spikes on the Pin-head itself. **Fig. 12.**—A, B, C, D, Forms of Butterfly Nuts; E, Bead Form of Nut; F, Disc Form of Nut; G, Stem pierced for passage of Pin. **Fig. 13.**—A, Improved Arrangement for Interchangeable Pin and Stud, with Screw soldered above the Centre; B, Pin and Stud as usually made; C, Another Method, where a small Screw (S) can be made to go through the Male Screw on either Pin or Stud to prevent the Setting coming unfastened.

in Indian ear-rings, which doubtless arises from the same cause—viz., that to produce a screw to advance by turning it to the right, it is necessary to turn the thread in the opposite direction. In place of the groove, a thin wire is sometimes coiled round and soldered, like Fig. 3, E; but this is a formation that is not much used.

*Other Kinds of Pin-stems.*—It is time that we got along with a description of other stems, presuming that the reader will fit the details already given on to those that follow.

*Old English.*—Fig. 5 is made from simple square wire, twisted. If the wire be polished before twisting, the result will be better than if it were done afterwards. You may use the hammers to this twisted stem if you want to spoil it; not otherwise. As you see by the diagram, it is this pattern we find in old work.

*Lace Pin-stems* (Fig. 6, A).—The crinkled one is an approved form for lace pins, where a sharp-edged groove might cause damage. These were formerly used for gentlemen's scarves as well.

A slightly varied form (Fig. 6, B) to this is simply made by twisting the middle of the stem wire round a small mandrel; then after removing the mandrel the wire is pulled out again, until some slightly waving form only is left.

*Corkscrew Stem.*—Fig. 7 is intended to make its way into the scarf corkscrew fashion. I have for the last few months looked in vain for an older pattern of this in shop windows. If anyone should have to make one with several turns, the easiest way I know is to take a large carpenter's screw, and coil the wire in between the threads; this will give regularity of spiral, and do away with nearly all the plier work—which is, as we know, the thing to be avoided in all wire-work. Fig. 7 has lately been introduced by Messrs. Perks & Sons, of Birmingham, and it undoubtedly deserves a fair trial.

*Screw and other Sockets for the Pin-stem.*—So much, then, for pin-stems; now for the means of attaching the stem to the ornament. It seems that there are three courses open to us. Have I not met that phrase before? The first and simplest is by soldering it direct on to the pin-head, as the French do, for the greater part; secondly, by making a female or socket mount on the pin-head, and in this to screw the stem; thirdly, instead of screwing the stem in, we can pewter-solder it into the socket.

Are there any rules or principles to bear in mind with regard to the way any or all of these are to be attached? Yes; for in the first place we have to show the ornament, whatever it is, to the best advantage. To do that, it should look well out to the front, and just a little upwards. It should remain steady in that—the best—position, neither leaning first to one side, then to the other, as the pins made from the convertible pins and studs do too frequently.

Two things are to be obtained, then: first, to show the ornament; secondly, to keep it steady. The way they are managed is shown in Fig. 8, A, where the front of the pin-head makes a good average angle with the stem; and for the second, you will notice that the space between them is about sufficient to let the scarf pass easily, and no more.

The scarf *must* be allowed to travel unimpeded as near to the top as possible—just like Fig. 8, A, in fact. It should never be stopped by either a peg like Fig. 9, A, or by having the "stirrup" as low down as Fig. 9, B, nor should the pin-head be tilted like Fig. 9, C. These three were sketched from pins I have had through my hands within a month of writing this, so it is evident that some people don't know or don't think about this.

The space left between stem and pin-head should in all cases be as shown in the side view of Fig. 8, A; perhaps it will be clearer if Fig. 8, A, and Fig. 9, C, are contrasted. Does it need any words to point out that Fig. 8, A, is right and Fig. 9, C, is wrong?

Our model for position and space between the head and stem is Fig. 8, A; something allied to that we are to obtain, be it plain soldered stem, forked stem, or socket (stirrup) and stem that we are using. If that is understood, we can get on towards a finish, for a mere row of sketches of different arrangement will give all the information required, and but little description will be called for.

Fig. 8, A to H, are a few of the different ways that the stem is attached to the work; they are various and general forms of (stirrup) sockets, which are employed when the stem is to be either screwed or pewtered in.

The centre of all of these can be made either from chenier or from a grain of gold run up on a piece of charcoal, in which a small round depression has been made with a doming-punch, or else from a coil of small rings soldered together.

There are yet two ways not spoken of. They are illustrated in Fig. 5 and Fig. 10. The first is where the stem is soldered straight into the ornament, which will be either globular or egg shape in form, such as a pearl or a lapis, gold or coral bead. The other (Fig. 10) is when the ornament (a coin or pearl pendant, may be) is to swing, then this form of stem is used; it is sometimes called the "shepherd's crook."

*Additional Means of securing the Ornament.*—Fig. 5 has already shown one direction in which attempts have been made to obtain more security for scarf pins; another class of additions for the same purpose is indicated by Fig. 11, A, B, B'. These consist of a spike or spikes, which are to be so placed that they will catch in the tie and prevent the pin riding up.

Fig. 11, A, shows the spike soldered to the stem. Now, as this cannot be screwed in the socket, it must be pewtered in to make the part that fits the socket, and the socket itself either square or oval; this is, of course, to prevent the stem turning. The pewter solder might hold it all right, but it is not worth while to trust to it more than is absolutely necessary.

Fig. 11, B, is a double spike arrangement, which you see is part of the "stirrup," consequently part of the head of the pin. To use this one will mean that great care must be exercised in getting the points hammered hard after the work is coloured—the very last thing, that is. The points themselves should be polished bright.

Another way of obtaining extra security is to form the end of the stem into a screw, and make a nut to fit on it. Any shape nut will do, providing that it is large enough for the wearer to handle conveniently; but one of butterfly shape (Fig. 12, A, B, C, D) will lay flat, and would be more comfortable to wear than one like Fig. 12, E or F. This screw and nut arrangement is the best for safety, and is consequently the one generally employed, in spite of the way which the screw catches the silk.

The stem, when used with these, requires fixing firmly, for it has to resist the nut's withdrawal. Several times have I had the pin given up to me as finished, ready to send to the customer, and on trying the nut I have had the pin-head come off instead. This sort of thing does not improve one's temper much, neither does it do much to heighten one's opinion of the workman.

The more I see of life, the stronger grows the feeling that to succeed, all that is necessary is a little common sense, conscientiousness, and industry. Ability to make articles well goes for little or nothing when such little discrepancies as the one above referred to are continually cropping up—and they do crop up almost daily. In a former paragraph, the way to keep a stem steady when pewtered is spoken of.

The last dodge for preventing loss that comes to mind is that of a perforated stem, like Fig. 12, G, where a common pin is intended to be pushed through the scarf and the stem. Many other ingenious ways have been brought out from time to time, but as they have not got into very general use, it does not appear worth while to describe them.

*Combined Pin and Stud.*—Perhaps this is the place to say a word about the ornaments now made to do duty as both pin and stud. Perhaps it is; but as nearly the whole of them make a good stud and a bad pin, it occurred to me that this matter more properly belonged to the paper yet to be written on Studs.

However, as it may be a long time before that gets printed, I have decided to allude to the matter here. It is a matter of everyday experience for me to have these studs and pins through my hands, and it is almost a universal custom, I find, to put the screw right in the centre. Now, for a stud that may be all right, but for a scarf pin it is not right; it cannot set properly in the scarf, as you can see by taking a walk where the wearers of such things most do congregate. Apart from that, you and I know that it is necessary, five times out of six, that we should be able to keep one direction of the stone—up and down, as it is called—either on account of such shapes as oblongs, drop shapes, or ovals, or to retain the proper position to show off the play of light in a cat's eye or moonstone.

To attain this fixed position of the ornament, as well as to get it to fit better on the scarf, I carry out this notion whenever the size of the ornament allows me to do so. It is simply to put the screw above the centre; this tends to keep the pin steady, and when used as a stud no inconvenience is found if the pillar of the stud be made oval: the screw, of course, fitting in one end (not the centre) of the oval pillar. Fig. 13, A, will show all the details of this, while the ordinary method is shown in Fig. 13, B. Another way is shown in Fig. 13, C. Here the screws are much larger in diameter; and as but two or three turns can only be used, it is well, where possible, to add a small screw, S, which will pass through both mounts, and so prevent the small amount of unscrewing which might result in the entire loss of the jewel.

A paper on Scarf Slides will follow this shortly.

## A WARMING PAN.

BY J. L. D.

A MOST desirable bed companion in cold weather is a jar or bottle of hot water tucked away somewhere in the region of the feet. A jar, however, possesses some disadvantages. Its capacity is limited, its shape is not often all that could be desired, and its cork sometimes does not perform its duty with becoming propriety.

To remedy these defects, I was asked to design and make a tin receptacle for hot water, which would not alone keep the feet comfortable, but act as a warming pan by being placed in the middle of the bed half an hour before its owner. I decided that in shape it should be oval, and its length one foot. For its construction I procured a sheet of best tin, 12½ in. by 17 in., and bent it over a broom handle into an approximately elliptical shape. The ends I joined together with the familiar folded joint such as is seen in almost any tin-plate vessel. I also ran a little solder along the joint. I found, on measuring, that the ellipse was 6 in. by 3½ in. I ought to mention that the sheet of tin was bent so that its greater length was round, the body of the warming pan being thus a little over 12 in. long. By means of two pins and a bit of twine I drew an ellipse, 6½ in. by 4 in., on a piece of cardboard. This I cut out with the scissors, and used as a pattern. I then procured a piece of sheet copper, 6½ in. by 8 in., and as thick as a threepenny bit, and from it cut two ellipses like the pattern. I then scribed lines ¼ in. from the edges, and flanged the ¼ in. at right angles to the body, like the top of a coffee canister. The flangeing I did over a piece of round iron, 1½ in. thick, and cut square at the end. When first I turned it over with the hammer, there were a number of puckers; but I tapped away at them, and when I thought the copper was getting hard, I annealed it by heating it to redness in the fire, and letting it cool again. I then tapped away again, and soon had the flange perfect. It also fitted the end of the body fairly, requiring only a little touch here and there to bring it into contact.

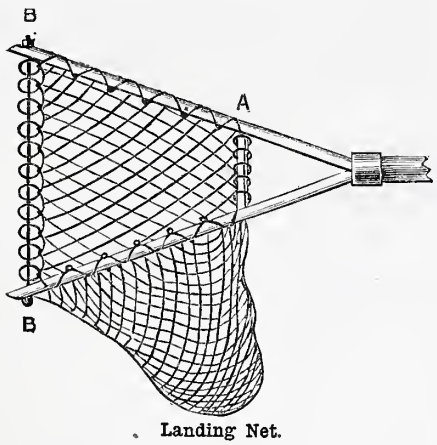
I then soldered the body and bottom firmly together, using only resin as a flux for the solder. I may here caution my readers against using spirits as a flux—at least, where tin is concerned. I have frequently seen the tin eaten through in holes from the action of the spirit. Before the other end, which we will call the top, is put in place, it would be well to furnish it with a screw-plug and handle. For the former I used a coupling, such as is used in a ½ in. brass cock, and for the latter a piece of wire, ⅛ in. thick, bent so as to fit four fingers comfortably, and fastened to the top with a strip of copper soldered all round. The top may now be put on the body and carefully soldered all round. A kettle of boiling water run in through the plug-hole will soon show whether there is a spot which requires further attention.

## ABOUT LANDING NETS.

BY LANCELOT L. HASLOPE.

THE easiest way to make a landing net is to net a sufficient number of loops on to a foundation as already described in WORK, and then to join them together into a circle by taking up the first loop that was made. If each succeeding loop is now taken up, a tubular-shaped net will be formed. When it is considered to be long enough, one end should be closed by reeving a piece of twine through the end meshes and fastening it with a reef knot. It is well to make the net deep enough, as otherwise the fish are apt to jump out of it as it is raised out of the water.

A better mode of making the net is as follows:—Net in the usual way a square piece of netting, sufficient to cover the ring to which it has to be attached: then fasten



Landing Net.

a piece of twine to the centre mesh, and attach this to the handle of a door or other suitable place. Now net round the square piece you have made, and a circular net will be formed, having a flat or nearly flat bottom, which will hold the fish more securely than one tapering to a point. In rounding the corners, the needle should be passed twice through the corner meshes, as this improves the shape of the net when finished. It is a good plan to net the last row of meshes—that is, those by which the net is secured to the ring—with double twine or twine of a coarser kind, as these meshes are apt to wear out long before the rest of the net. When the net is finished, it is laced to a ring of some kind with ordinary twine or fine copper wire.

Rings are made in a great variety of shapes. Stout iron or brass wire bent into form, with the ends turned outwards for two or three inches, so as to form a tang to go into the handle, answers very well, though it will be rather cumbersome to carry about. A great variety of collapsing rings may be purchased at the tackle shops. These usually screw into a handle, and thus take up but little room. The handle, when made of bamboo, forms a convenient receptacle for an extra top or two. On the whole, the best form of landing net with which I am acquainted is the one I have given an illustration of. The wood must be sawn down the centre for about twenty inches, and a ring or lasting passed round the end of the cut to prevent splitting. A short cross-bar is then inserted, as shown at A, and the ends secured by twine, as at B. The net is then laced on in the usual way.

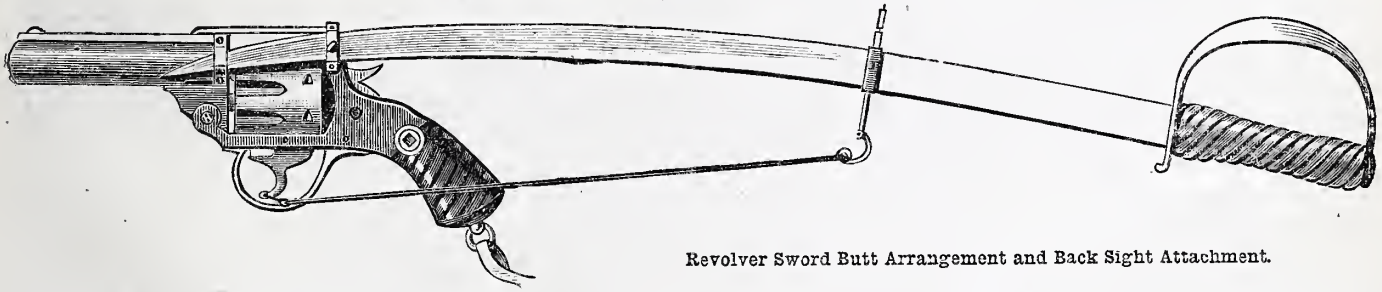
## MODE OF LENGTHENING A REVOLVER SIGHT FOR LONG-DISTANCE SHOOTING.

BY JOHN CHARLES KING.

THE revolver for military use is effective for aim only at close quarters. There are times when a dismounted cavalry-man who is without a carbine would be glad to use his revolver for a hundred yards mark, but with sights so close it is almost guess-work to attempt an aim at that distance.

His sword in this emergency might serve him well, if it were arranged for the purpose, and the revolver had staples to take the point of the sword to hold it up, the soldier using the sword-hilt as a butt to put to his shoulder, and a detached hilt-piece for sight and trigger, as shown by the annexed illustration. The revolver to have two flat staples on near side of butt, as shown, the rear staple to have a tightening nut screw to secure the sword to the revolver. The staples are lined with ebonite, to prevent abrasion of blade, sides, or edges.

*Description of Sword.*—A sliding peep-sight forms a part of the hilt, but detachable by sliding forward to a fixed limit, there to be secured by a spring stud, which engages into a recess in the side of the blade. This peep-sight has, at its lower edge of slide, a projecting piece terminating in a jointed trigger; at the point of this trigger is a small hole to take a bit of woven wire or whip-cord of suitable length to reach the revolver trigger, so that the movement of the sword trigger acts on the revolver trigger for firing. The additions proposed would not affect the ordinary service of sword or revolver.



Revolver Sword Butt Arrangement and Back Sight Attachment.

## SHORT LESSONS IN WINDOW MAKING.

BY G. LE BRUN.

### THE CONSTRUCTION OF CIRCULAR-TOPPED SASHES.

CIRCULAR and Gothic-topped sashes are two of the most difficult forms of windows that fall to the lot of the average house carpenter to construct; and as their use is confined to the more ornamental styles of architecture, they are not of common occurrence in the ordinary workshop: in fact, a man might work at the trade for years, and yet never see a window with a circular top made; therefore, a few general hints on such sashes may prove of use to the young workman, and enable him to better tackle any job of the kind that may happen to come in his way.

The general construction of the sides and lower part of these windows, whether "hung" or "deadlight," is almost identical with the forms of windows already described; but the top part is very much different in its putting together, and will tax the technical ability

of the worker who is not already versed in their making. A few special tools are necessary for the work. They are a circular-soled hand plane, which may be either an ordinary wooden hand plane cut to suit the required circle, or, preferably, one of the useful adjustable circular planes sold by Melhuish, in which the flexible sole can be bent to suit either straight, convex, or concave work by means of a screw (Fig. 1); a sash router to work the Gothic moulding with (Fig. 2); and a circular rebate plane for forming the glass rebate (Fig. 3). This last may be made by the worker himself, the iron being purchased. In using these tools, you have to fix the work

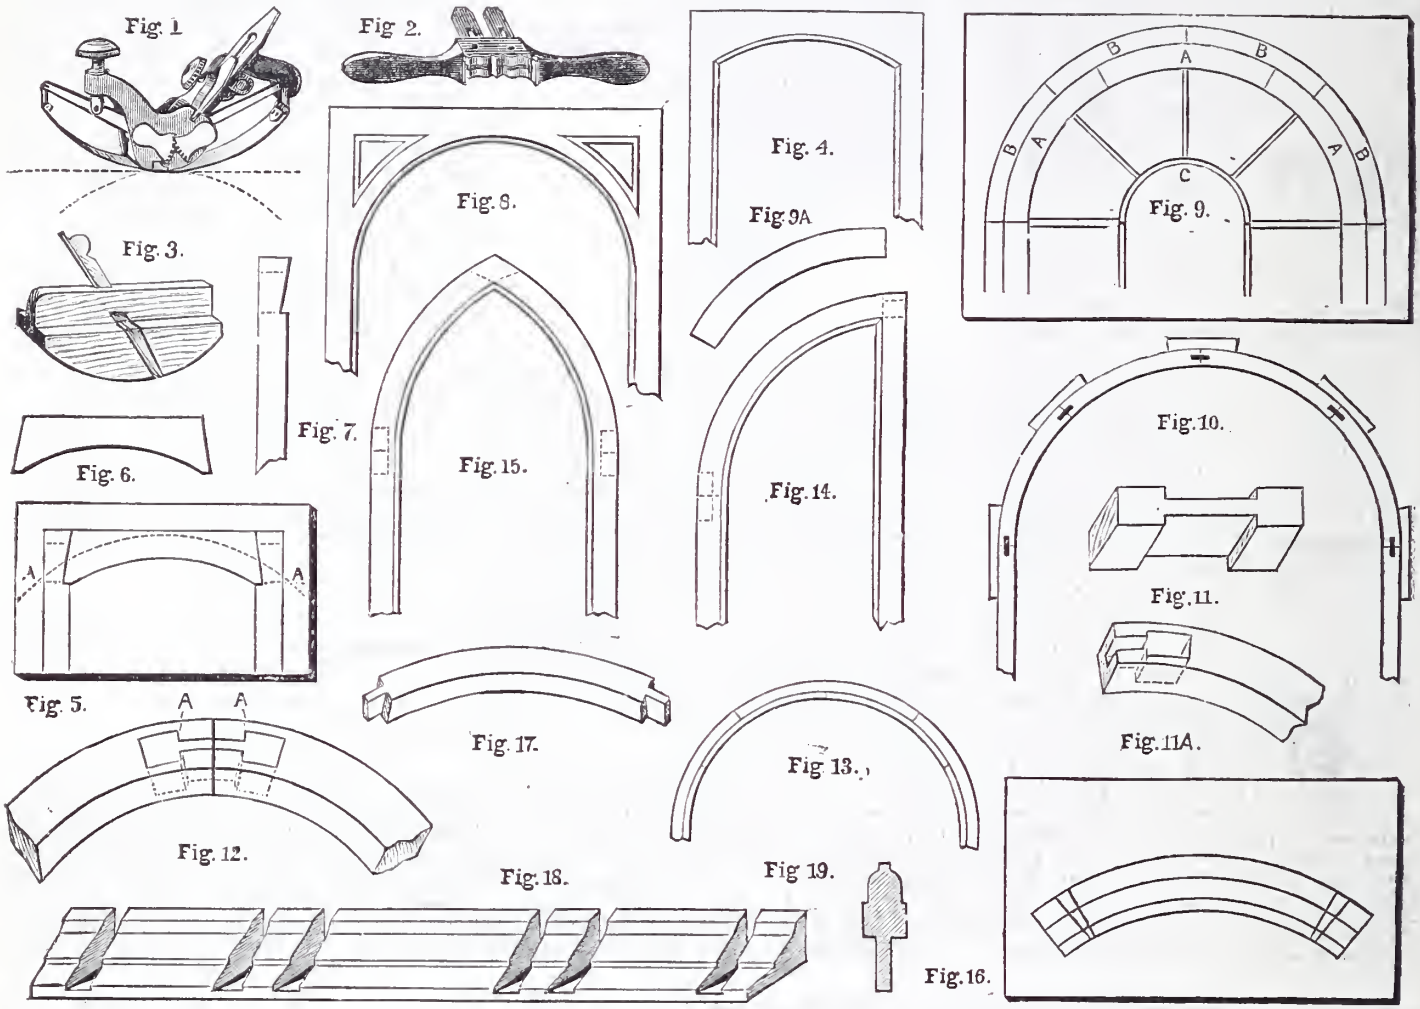


**Fig. 1.—Adjustable Circular Plane. Fig. 2.—Sash Router. Fig. 3.—Circular Rebate Plane. Fig. 4.—Top of Simple Circular Window. Fig. 5.—Board with Drawing of ditto. Fig. 6.—Mould for Sash Lintel of ditto. Fig. 7.—Top Part of Sash Tile cut in for Lintel Shoulder. Fig. 8.—Circular-topped Sash for Square Case. Fig. 9.—Drawing-board, with Drawing of Circular-topped Case and Hung Window. Fig. 9A.—Mould for Segments of Sash Top. Fig. 10.—Case Top, showing Mode of joining Segments. Fig. 11.—Shape of "Key" for joining up Sash Segments. Fig. 11A.—Mortise in Segment to receive "Key." Fig. 12.—Mode of keying Segments together. Fig. 13.—Mode of building up Sash-bar. Fig. 14.—Top Part of Gothic Window. Fig. 15.—Another Form of ditto. Fig. 16.—Board with Drawing of Circle Window for Corner or Turret. Fig. 17.—Rail of Circle Sash. Fig. 18.—Sole for Three-light Hung Window. Fig. 19.—Sash-bar for Plate Glass.**

firmly in the bench jaws, and work from both ends of the piece of curved wood towards the centre where the grain meets, as if you were to work the planes right round the circle, part of the wood would be torn up, and the job spoiled. This little matter will, however, at once make itself apparent to you when you commence the work.

One of the simplest forms of shaped window is that shown in Fig. 4, and in which the lintel of the sash, owing to the slight curve, is worked out of one piece of wood. To obtain the curve, lay a straight-edge across the wall opening, the ends just touching the spring of the arch; then measure the distance from the straight-edge (at the centre of the opening) to the top of the arch. Take a few pieces of matchboard of a sufficient length, drive them well together, nail two pieces of wood across the back to hold them together, and with a coarse hand plane level the overwood at the joints. This is to form a drawing-board. Lay it on the bench, and draw the top of the window full size on it, as in Fig. 5. Take a piece of thin wood, and make a mould the exact shape of the sash lintel between the tenons (Fig. 6). Your sash stuff having been prepared and "set out" in the usual way (so far as the lower part is concerned), take the mould and lay it on the piece for the sash lintel, which should be of a sufficient breadth to allow the same width being left at the thinnest part of the circle after it is cut as the width of the rest of the framing; mark it accurately at the ends and round the inside edge; cut out the circle with a narrow saw, make the tenons, and proceed to work out the glass rebate and mouldings. When finished, lay on one side, and mortise the stiles; after mortising, cut out the piece as shown in Fig. 7, to fit the bevelled shoulder of the lintel rail, which carefully fit into each stile, and then finish off the window in the usual manner. In a double-hung window of this description the case is made square in the ordinary way, the outside facing on the case lintel being kept wide enough to cut out to the required circle, which is denoted by the dotted line at A A in Fig. 5. A window of this kind can be made with a much deeper circle than that shown: in fact, the only limit is the width of the stuff you can procure to cut your sash lintel out of; but it presents a heavy appearance on the inside of the room, where the square side is necessarily seen. To obviate this heavy appearance, and still have the simplicity of a square case, the plan shown at Fig. 8 is sometimes adopted, two pieces of framing being inserted in the corners of the window, and the triangular opening thus formed filled in with coloured glass. This mode certainly looks much lighter than the solid wood, although entailing more labour. The size and bevels of the circled corner pieces are taken from a drawing made on a board, in the same manner as the previous example.

We now come to the real circular-topped window, where the whole of the top part, both of case and sash, must be worked out of the solid. The first thing to be done is to lay down the full-size drawing of the top of the window on the board, as in Fig. 9, in which A is the sash, B the case, and C the sash-bar. The top of the case may be in three or four pieces—more if the window is large. In this instance we will suppose it in four pieces, and the sash in three pieces: these pieces must be of an equal size, so that

one mould may do for them all. Make a mould for a segment of the case top (Fig. 9 A) and another for the sash top. Keep these moulds, say, 1½ in. longer than the exact size of the segment, as you will require a little extra length to allow for working. To get out your stuff, select a good piece of wood, of the requisite breadth and thickness. For the sash it will be 2¼ in. thick, while the case will require 6½ in. These can, by dint of much labour and an extraordinary amount of perseverance, be cut out by hand; but if at all within reach, take them to a saw-mill, and have them cut by a band-saw. Of course, in marking them off you will keep them full to the mould, so as to allow a little for loss in working.

Having the stuff cut, work it carefully to mould; lay it on the drawing-board, and mark it accurately for cutting; fit the joints together by means of a plane; try the segments together on the board while you are jointing them, so that you may keep accurately to the circle. When you have both the case and sash stuff jointed, it will be ready for putting together, which is done in the case top by grooving the ends of each segment and inserting a slip of hard wood, and by screwing pieces of wood of the same width as the case top, and curved to fit, on the outside. This method of jointing is shown in Fig. 10, and both slips and clamps should have a coat of warm glue. The same method is used to fix the ends of the circle to the pulley stiles of the case.

The sash top is put together by means of what are termed "keys" of hardwood (bolts and nuts are sometimes used). Their shape is shown in Fig. 11; the ends of the segments are mortised to receive them (Fig. 11 A), and they should be about ¾ in. less than the width of the sash stuff. Keys and mortises must be well smeared with thick white lead, and secured by driving in wedges, as at A, A, in Fig. 12. The lower parts of both case and sashes can now be put together, the tops attached, and the whole finished off. The sash-bar should be built up of two thicknesses of wood cut to circle, as in Fig. 13, the different pieces overlapping each other, and thus giving greater strength. The finished sizes must be taken from the board, and the mortises made for the reception of the straight bars, after which the moulding can be worked.

The case and sashes being ready for fitting, that operation is the same as described for hung sashes, but a little more care is necessary to fit the top sash correctly. If the window is a deadlight, little fitting into its place will be required—that is, if the sizes have been properly taken. Sometimes, as in the case of a hinged window, the sashes are made to open in two parts. Then the construction must be as in Fig. 14, where it will be seen the curved piece of the framing is secured to the long stile by the ordinary mortise and tenon, and the short stile by means of a key.

Fig. 15 shows the top of a Gothic window, which is halved at the apex, and secured by being well screwed together from both sides, keys being used to attach the top part to the stiles. In a flat-headed Gothic window this arrangement would be reversed, a key being used for the apex, and the stiles halved for the bottom.

In the construction of all the foregoing styles of window the greatest accuracy must be observed in laying down the drawing on the board, so as to get accurate sizes; and also in making the moulds, marking off the lengths of the segments, and making the joints. For without accuracy in these particulars you cannot expect to make a well-fitted window.

Another kind of circle window, and one a trifle easier to make, is that with a square top, but with a curve outwards—such as might be used at the corner of a house or in a turret. In this case we lay down on the drawing-board the curve of the window-sill (Fig. 16), from which drawing we get the curves and sizes of the case, sole, and lintel, and the sash-rails. Moulds will be required as follows:—One for the case sill, which also serves for the case lintel; one for the rails and bars of the lower sash; and one for those of the upper. The case and sashes are put together exactly as in the square form, the sash stuff being mortised and tenoned as usual, the bevels of the tenons being got from the board. Fig. 17 shows a rail with its tenons cut. The one great drawback to this form of window is the difficulty of procuring glass for it, as the panes must be bent to fit the curves, and are comparatively expensive and difficult to procure, especially in country towns, where much delay in replacing a broken pane would be found; in fact, I have oftener than once been compelled to wait for over three weeks for a piece of curved glass to replace a broken pane, to say nothing of the trouble and annoyance caused to the inmates of the house. Still, these curved windows have their uses, and must be made when occasion requires.

In all the forms of windows described in this paper the sash beads, parting beads, etc., for the curves must be worked out of the solid, the curves for them being got from the drawing-board.

It sometimes happens that two or more windows have only a thin stone mullion between them, and very often houses are built with three windows in a group—a large one, with a smaller on each side. When this takes place, the windows, if hung or hinged, generally have their cases made as one. The sill of a hung window of this sort is shown at Fig. 18, with the cuts for the pulley stiles (the case lintel is cut in the same way), and should clearly explain the construction, which otherwise is the same in all details as an ordinary case.

If plate glass is to be put in sashes, the glass rebate should be at least $\frac{5}{16}$ in. deep, and this remark will apply to all the forms described in these papers. Where there are sash-bars, they must be kept heavier than those in a window that is glazed with sheet glass, and usually are about ⅞ in. or 1 in. thick. When the moulding and rebate have been run, they show a section like Fig. 19.

To fully enter into all the details and intricacies of circular and kindred sashes would fill many complete numbers of WORK, and is far beyond the scope of a necessarily short paper like this; but the intelligent workman, having his wits about him, may gather from these few hints some idea of "how the thing is done."

## MANDOLINE MATTERS.

BY MADRILENA.

THERE are probably other readers of WORK besides the writer who intend to follow the admirable instructions given by "J. G. W." on p. 229, Vol. II., as to how to make a Mandoline, therefore the present article is likely to be of service. Although it may, as a rule, be true that whatever is now made is superior to what was constructed centuries ago, it is by no means so certain that this applies to "shell" instruments—of which large family the mandoline is a member. In fact, the most cursory glance at a number of ancient models will convince the reader that the latter embody elegances which are wanting in modern examples, and which appear to have lapsed into desuetude for no sufficient reason. As an example, take the modern neck, which has the section shown in Fig. 1. Contrast with this the ancient form, of which Fig. 2 shows a section. The groove running the entire length of the latter *must* be a great convenience, and must necessarily facilitate good stopping or fingering. In this groove the thumb travels. Here, then, is tip number one for such as are contemplating the construction of a mandoline. The form of back shown in Fig. 3, and which was copied from a Chiterna of the seventeenth century (Italian), is also one which might be revived to

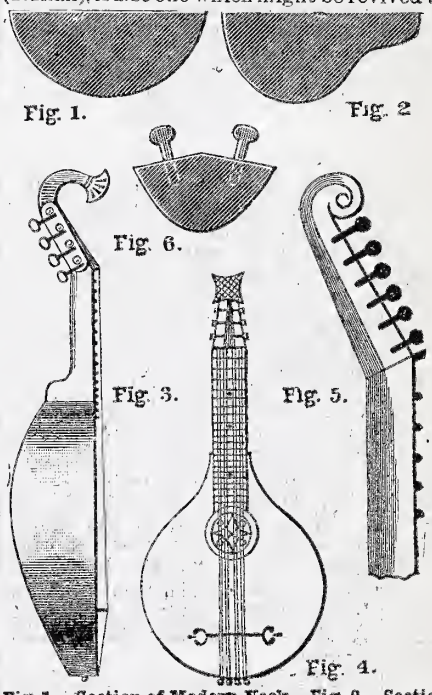

**Fig. 1.—Section of Modern Neck. Fig. 2.—Section of Sixteenth and Seventeenth Century Neck. Fig. 3.—Side Elevation, showing Shaping of Back and Head. Fig. 4.—Front Elevation, showing English Cithern Model with closed Rosette. Fig. 5.—Rough Sketch of Ancient Solid Head. Fig. 6.—Section of Solid Head, showing method of fixing Pegs.**

advantage, especially as it involves no difficulties in the making, while the model for the belly may well be copied from our old English "Cithern," as in Fig. 4. This figure also shows the "rosette," or sound-hole, *pierced* instead of cut out. In some of the old instruments which the writer has recently inspected these saw-pierced rosettes are marvels of beauty, whether perforated through the belly direct or inserted in thin brass or gilded wood. Such ornaments have only fallen into disuse since makers have ceased to consider themselves artists, and, as tradesmen, have wanted to display a label. The graceful finish to the head in Fig. 3 is also easy of accomplishment, and offers great scope for ornament in the way of carving, etc. The machine there shown is, of course, a modern innovation. For such intending makers as are not skilful workers, or who do not care to go to much trouble, the old solid head, with the pegs on the front, will also prove a welcome "tip." This is shown in Fig. 5, where, however, only one of the two rows of pegs is given.

Its construction will be seen from the section, Fig. 6. Another "wrinkle" is to make the finger-board slightly rounded on the face, the frets, of course, following the same contour as do the nut and the bridge. This is the rule with Portuguese instruments, and is a help in fingering.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Hard Wood.

In the foregoing chapters it has been assumed that the amateur has dealt with wood presenting no special difficulties. The mastery of the simplest tools, and understanding how to mark out in a proper manner the various joints already treated, have, we may be sure, offered sufficient difficulty to the persevering student. But when wood of special beauty of appearance, rather hard, or still worse for the beginner, of various degrees of hardness, is used, the trial of the amateur's patience is severe.

Oak, mahogany, walnut, sycamore, and ebony, all more or less used by amateurs, have this in common; they all require well-kept planes, with the irons not ground too thin or sharpened too rounding, and set in the planes so that only thin shavings are to be removed. Care must be taken to plane the right way of the grain, although it is sometimes very puzzling to decide which is the most favourable direction to plane. As to the saws—better abandon the rip-saw, and in its place use the hand-saw, and for cross-cutting the panel-saw. It will be found that hard woods have a very different appearance, according to the relation of the plane of the surface to the diameter of the tree. Thus, when, as in the centre boards, the surface nearly coincides with the diameter, not only are the boards of greater value because of their greater width, but also because they contain, in the fullest extent, the beauty and character of each variety of wood.

Therefore, to obtain the best effect from the harder woods, it is needful to make the cut across the centre of the tree. The surface of the board is then parallel, or nearly parallel, with those radial lines which run from the centre to the outer surface of most of the hard woods. If the end grain of a piece of oak, beech, or sycamore is examined, my meaning will become clear. In cases where a pair or a set of panels are to be made, and the grain of the wood is not obscured by paint, it is best to have all the panels alike in appearance; or, if that is impossible, arrange them so that the eye is not offended by the beautiful appearance of one panel and the poverty of grain exhibited by the next. Oak, in the form of staves (6 in. wide, 3 in. thick), always has the grain in a favourable way for panels. In every case obtain boards long enough for all the panels required, or by two consecutive boards.

A tool is needed to clean off the harder woods which I have not mentioned. It is at once the simplest tool and the most difficult to use—merely a piece of sheet-steel or a piece of saw-blade—but the sharpening is the rub. Try to do it thus: With a little water grind the edge on the paving-stone, holding the scraper upright and aiming at getting a square edge. With a hard steel tool, as a strong bradawl or a gouge having a polished surface, you burnish the edge as if you tried to bring the metal from the edge of the scraper *towards* the angle formed by the edge and the flat surface. Do this to each edge of the tool, and when well done, you have four sharp edges, which will remove a portion of the surface of the wood in a state between dust and shaving, not tearing pieces out of the work as sometimes a plane will do. This tool is a most valuable one, if good, but if too hard, it cannot be sharpened; and if too soft, it will not retain its edge.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 113.—Set of Castings of the Quarter Horse-Power Steam Engine.

It will be within the remembrance of every reader of this, the third volume of Work, whether they take interest in the subject or not, that a series of papers has appeared on "The Construction of a Quarter Horse-power Steam Engine," comprehensively worked out and carefully written by "F. A. M.," whose initials are well known as being those of a contributor to most, if not all, of the mechanical and engineering serials of the day.

I have had the pleasure of a personal acquaintance with "F. A. M." for many years, and I can speak of him from the experience of these years as an able, practical workman and conscientious writer, who never attempts to handle any subject that he does not thoroughly understand, and who endeavours to the utmost to place any subject that he does take up before the reader in such a way that few can fail to understand all that he says and describes, and who never shrinks from any personal trouble to arrive practically and experimentally at such knowledge as may be needful to enable him to do full justice, first to the matter under consideration; secondly, to his readers; and lastly, to himself.

Such is "F. A. M.," who has described in these pages the making of a Quarter Horse-power Engine from commencement to finish, and I am glad to take advantage of this opportunity to bear testimony to his skill and conceptive power as a practical workman and to his worth as a writer.

Doubtless it will have occurred to many that the utility of the papers to which reference has just been made was somewhat marred by the fact that, in making the steam-engine described, it would be necessary for the workman to make patterns first of all, and secondly, to get castings of the patterns before he could enter on the work of fitting and putting the parts together to make the steam-engine itself. It appeared most necessary, both to "F. A. M." and myself, that every would-be engine maker should be able to avail himself of a set of castings of all the parts ready to hand, and with this view the needful patterns were made under the personal superintendence of "J. H.," another valued contributor to Work.

I mention these facts because I think it desirable that every reader of Work should know something of what I may call the secret history of these matters, and that they may gather, from a knowledge of that which has been done in this case, that all who are concerned in the preparation and production of Work do all that lies in their power to benefit its readers, and are taking thought for them even while it may seem to those who are not behind the scenes that they are careless and indifferent to the appeals and expressions of those who seek their aid.

Well, the castings of this engine are now in existence, and may be easily obtained by anyone who may wish to have them. Further, a complete set has been sent to me for examination, and I am happy to be able to testify to their excellence. Forty-four castings and forgings are required for the engine alone, and these may be purchased for £1 9s. 6d.—no very great sum when their number is taken into account, and the value and power of the machine that they unite to form. Beyond these, twelve more castings are required for the feed-pump, costing 5s., and ten more for the governor, costing 3s. The necessary lubricators, stop-valve, etc., can also be obtained, and all the screws and nuts.

Everyone, I think, who purchases the castings should order the cylinder bored, and the fly-wheel bored and turned. This work will be carried out by the maker of the castings and forgings for 15s. 6d. It is machine work not usually done by the fitter, who will have plenty of work to do, which if he accomplishes successfully, may think himself fairly entitled to say that he "made the engine."

The reason that there are such a large number of parts is because everything has been done that can be done by the pattern-maker and moulder to help the amateur workman; for every little brass nut a pattern has been made, and some of the castings are very small. Amongst such a multiplicity of small etceteras, it is very easy to make a mistake, and I was very anxious that a conscientious person should be persuaded what may even now prove to be an unprofitable task—I mean to the man who makes and sells the castings, and not to any individual buyer, who, at any rate, gets excellent value for his money, and who, if he be possessed of skill and patience enough to put the parts together in a workmanlike manner, cannot fail to find himself on the right side of the hedge.

Mr. Henry Milnes, of Bradford, whose advertisement appears in our "Sale and Exchange Column," is the man who has laid hold of it, and he is determined to do the thing properly, whether it pays or not. Anyone who wishes for a set of castings to work up during the fag end of this ungenial and trying winter, from which those who are left of us will soon emerge, and tho coming spring, may send him their money in perfect confidence that they will not be disappointed.

### 114.—Calvert's "Mechanics' Almanack."

All workmen, whether amateur or professional, will find Calvert's "Mechanics' Almanack and Workshop Companion," published by Mr. John Heywood, of London and Manchester, a useful addition to the practical *vade mecums* with which they provide themselves year by year. Of the usual almanack matter that is found in this, in common with other year-books of this class, I need say nothing: it is, indeed, in the incidental brief papers, tables, and special information on matters of interest to workmen of all trades and callings involving manual labour that its main value consists. It contains a useful Wages Table, for example, for a week of fifty-three hours; a short article on "The Art of Doing our Best," which most of us may read and act on with profit; hints on "Human Life and Brain Wear," showing what may best be done to prolong the one and lessen the other; some desirable papers on "The Cost of Maintaining Patents" and "Patent Agents;" and a "Table of the Size, Weight, Length, and Strength of Iron Wire," showing for each number its diameter in inches and millimetres, its weight per 100 yds. and statute mile, the length of a bundle of 63 lbs. and of 1 cwt., the area of section in decimal fractions of a square inch, and the direct strain for wire annealed and bright. Woodworkers will find the notes and remarks on the timbers chiefly used in carpentry in the United States both interesting and useful, and the same may be said of the brief paragraph on the "Strength of Fir and Oak." In point of fact, it may be fairly said that it contains something for everybody, and that no one who takes it up can put it down again without finding some paper or paragraph calculated to instruct and interest the reader.

The Editor.

# SHOP:

## A Corner for Those who Want to Talk It.

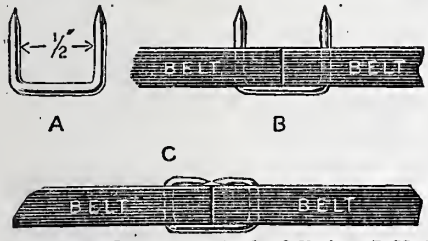
*** In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given.*

### I.—Letters from Correspondents.

**How to Frost Cardboard.**—Reader writes:—"Hold clear glass in a gas flame until red-hot, then plunge suddenly into cold water, when it will powder itself. Go over the cardboard with a brush dipped in clear gum. Then sift the glass powder on it with a fine hair sieve."

**Leather Belting Joints.**—E. A. P. (*Tullow*) writes:—"The following is a good way to join round leather belting. Round leather belts are universally used on lathes from 2½ in. to 5 in. centres, and have many advantages over a flat belt but for one drawback—viz., the impossibility of joining them securely. Hooks and eyes of a special make are generally employed, but often fly off and get lost, thereby causing much annoyance. The plan which I have adopted is similar to that by which sewing-machine belts are joined, and is very simple and secure; its only fault is its firmness, as it is impossible to take it asunder without opening



**Leather Belt Joints—A, Staple, full size; B, Mode of joining; C, Join complete.**

the join. It consists of a U-shaped piece of wire about ½ in. broad, the two upper ends of which are sharpened with a file, and which can be easily made with pliers. Two holes are made in the belt, one in each end; one side of the wire staple slipped through each, the projecting ends turned in and well clinched; then you have a good reliable join, which makes little or no jump over the pulley, and costs practically nothing except a little time and care. Be sure, however, there is no twist in the belt before joining, as it would interfere materially with its working. The annexed sketches will explain my description more thoroughly. A is the staple; B shows mode of joining; C is the join complete."

**A Good Furniture Reviver.**—E. A. P. (*Tullow*) writes:—"Now that spring is coming round once again, all the gentle sex will be busy with the annual 'spring cleaning,' and, of course, the good man of the house will be expected to provide some suitable mixture with which willing hands and arms will make the chairs and tables shine over and over again. The following is an excellent recipe, all the materials of which can be very easily obtained, even in the most out-of-the-way places. Besides thoroughly cleansing the furniture, it leaves a splendid polish, which has the further advantage of not being easily soiled by finger-marks. Spirits of wine, 1 pint; vinegar, ½ pint; boiled linseed oil, ¼ pint; turps, ¼ pint. Mix the spirits and vinegar first, shaking well till of a creamy colour; then add the other ingredients, and mix all well together, keeping tightly corked. Apply with a clean, dry cloth, rubbing well in, and polish off with a dry flannel. The cloths used must be perfectly dry, as the least moisture is fatal to a good polish."

**Gold Lace.**—G. E. B. (*Lewisham, S.E.*) writes:—"As I am daily engaged in preparing the material employed in the manufacture of gold lace, perhaps you will kindly allow me to add a few words to the closing paragraph of the reply to L. N. (*Oldham*) by H. S. G. in 'Shop,' p. 667, Vol. III. H. S. G. says, 'Gold lace (so-called) is, I believe, never of gold, but either silver or copper wire electro-gilt.' Some so-called gold lace may be made of such material, but the real gold lace worn on officers' uniforms is not made of electro-gilt silver and copper wire. Lace wire is not made of solid gold, but of silver coated with gold by the fire process. By repeated annealings, the coat of gold becomes embedded in the surface of the silver wire. The durability of this gold coat is determined by its thickness, and this by the price customers are willing to pay for the gold lace. With the price of pure gold at 85s. per oz., only a thin coat of it can be expected on gold lace wire sold at 8s. per oz., and yet this is deemed a fair price to pay for a fairly good material. We are often pressed by competition to quote even lower prices than this. Only a few days ago we were asked to supply a good gold lace thread to sample at 2s. 6d. per oz., the pure gold in the sample itself assaying to the value of 2s. 5d. per oz.! Whilst customers demand skilled labour at such a low price, they cannot reasonably expect manufacturers to sell gold at a loss. If customers are willing to pay a fair price for gold lace, it can be made to wear well and will bear cleaning; but the low-priced lace forced into the market by foreign competition cannot be cleaned. The only way to restore it is to renew the lace."

**Hints for Fellow-Amateurs.**—H. P. (*Bracknell*) writes:—"A great saving of time and trouble may be obtained by buying common articles instead of the raw material. A rolling-pin of beech may be had for about 3d., and many articles turned out of it without all the roughing-down process, and as cheap as the amateur would buy the rough wood. Boxwood roller-skate wheels, at one penny each, will make a great variety of useful lathe adjuncts without much trouble. Napkin rings also can be made in a few minutes from them. Hard-wood draughtsmen, to be bought at 6d. a box, are useful. A halfpenny, or other bronze coin, makes a good metal washer when wanted in a hurry. A paraffin cask is a mine of wealth for dog kennels, wash-tubs with handles, chicken coops, cupboards, tubs to plant trees in, or as a stand for the greenhouse, using the inside to fumigate plants in; the wood can be straightened, and will make nice oak boxes or frames—in fact, a multitude of articles, according to the inventive genius of the worker. Amateurs generally have to pay heavily for materials, as they do not know where to get things at trade price. The most valuable find for me was Cotton & Johnson's, in Gerrard Street, Soho, where I can get any little piece of metal (silver included) of any dimensions; also any tool under the sun. Another handy place is Allen's, in High Street, Bloomsbury, for castings in brass, gun- or hell-metal. I make my own patterns in wood, and get them cast there at trade price; he has a lot of useful castings in stock, which saves the trouble of making patterns. For those who have no overhead motion on their lathes I would suggest that they buy a spindle, used by jewellers, with a hand wheel; this can be fastened to the slide-rest, and with a few ornamental and cranked drills a lot of useful work can be done. I hope other amateurs will give any little wrinkles they possess to their brethren."—[Yes, it is to be hoped other readers will give wrinkles now that you have set so good an example; but while on the subject of "handy shops" you should have mentioned Mr. Caplatzi's veritable museum, which we have seen, at 3, Chenies Street, Tottenham Court Road, London, as advertised in Work.—Ed.]

### II.—Questions Answered by Editor and Staff.

**Photographic Expedients.**—G. T. (*Liverpool*).—If G. T. will carefully read the article in question, he will find most of his questions already answered. The two pieces of tube are to allow the combinations to be changed. The one attached to the camera by the flange is merely a receptacle for the other pieces containing the lenses. Each piece may contain two lenses of different foci. Only two lenses are used at a time, although more may be. In combining two, the focus will be found to be about half that of the shortest focus, and the stop is to be placed close to the lens in front; but all this was told in the article in question. Read it again. Ask for lenses whose combined foci will be the length required. If you want 12 in., ask for two 24 in., and so on.—D.

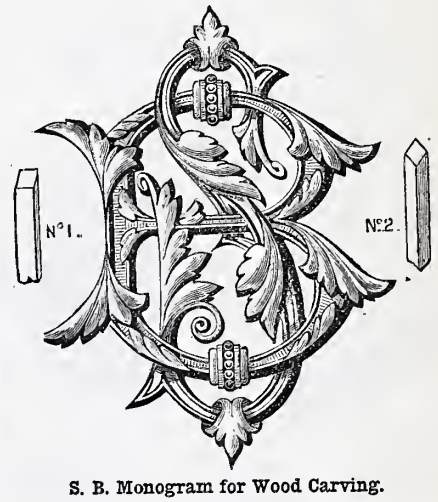
**Stereo Metal.**—J. H. M. (*Southborough*).—If you will stir your melted metal with a red-hot bar of iron, the zinc will cling to it. Repeat the operation till the whole he removed, keeping the surface skimmed for dross during the operation. The metal containing zinc is of no use either for stereotype or electrotyping. Another plan is to tie up in a rag a piece of borax about the size of a walnut and plunge it to the bottom of the melting-pot, then let it remain till the surface of the metal ceases to bubble. The zinc will rise to the surface and can be skimmed off.—J. F. W.

**Wood-Carver's Composition.**—J. W. (*Kendal*).—You can very well mix emery powder with oil, so that it makes a sort of paste, and when put on a piece of thick leather, it can he used for the purpose you mention; but it may he considered rather a rough treatment, and fine tools can, at all events, never stand it. The best remedy I know of is the one used by professionals: simply to sharpen the tools by rubbing them slightly over a small oilstone, moistened with some good oil. It may sometimes he rather difficult to obtain these stones, because few shops keep them, but I know by experience that you can get them at the ironmonger's, 379, Oxford Street. I am sorry I have forgotten the name of the firm. The price of them is from 1s.—T. N.

**Electro-Gilding with Alloyed Gold.**—E. L. (*Wednesbury*).—Alloyed gold may he deposited from an alloyed solution of the double cyanide of gold and potassium, but the process is not easily managed, and the deposit not always certain. The following process is recommended by Elkington and Co., who supply anodes for the purpose from their London works—Myddelton Street, E.C.:—Dissolve 8 dwts. of the alloy in each gallon of solution containing 4 oz. of commercially pure cyanide hy the usual battery process. Work the solution at a temperature of from 160° to 170° Fabr., using the alloyed anodes. If the colour is too dark, reduce the density of the current. The anodes for 18-carat gold gilding are advertised at £3 5s. per oz. In my experience with this alloyed gilding I find that the colour varies with each slight variation in current density, which may be brought about by a different size of anode, or size of article being gilded, or size of slinging wire employed, or change in temperature of the solution. I think, therefore, that it would be impracticable to obtain solid articles in this alloy hy the electro process. Your question respecting the electro deposition of iron is similar to that of H. C. (*Surbiton*). I fear you would not get "a deposit of iron strong enough to stamp copper." The iron would be very brittle. If you have any useful novelty in electrical appliances, proved by you, send it along on approval to the Editor. If it is worth anything it will appear in "Shop."—G. E. B.

**Organ Building.**—G. (*Sydenham*).—This subject is under consideration for future numbers. Meanwhile, many details have been explained in "Shop." Purchase the indexes to Vols. I. and II. of Work, price one penny each.

**Book-Cover Monogram for Carving.**—Amateur Wood-Carver.—Should this design he of use to any of our readers who are not advanced enough to execute it in carving, they could reproduce it, either in wood or metal, by the more simple method of piercing; then, to "relief" the scroll-work a little, the surface of the letters immediately around the ornament should he slightly sunk and boldly lined or "threaded" with a square graver. When sinking and threading, nearly all the cutting



**S. B. Monogram for Wood Carving.**

should be sloped towards the ornament, the object of so doing heing ohvious. To finish the ornament, all that is needed will he a few broad, decided graver cuts to indicate the sweep of the scrolls. With regard to the gravers technically termed "squares," two, including handles, can be purchased for ahout 6d., which should he prepared in the manner indicated above: No. 1 to be used for the sinking, or for even hevelling the edges of the letters, and No. 2 for the lining.—A. C.

**Lathe Appliance.**—J. R. (*Burnbank*).—Yours is a good and simple way of doing the work, and no doubt was quite effective. It is a kind of spherical slide-rest, except that it can only do hollow curves. A spherical slide-rest is a very old and well-known appliance, and you have not quite attained to it; yet your contrivance is all you wanted for the work you had to do. To make your appliance available for balls as well as hollow curves, the worm-wheel must be down close to the main plate and secured hy a loose collar on the pin underneath plate, the top of worm-wheel to have a T slot right across it to take the tool-holder. Then, with a larger and stronger worm-wheel, you could work round the outside of a ball.—F. A. M.

**Where to get Tinfoil.**—Gas-lighter.—The best firm to supply you with tinfoil suitahle for repairing an electric gas-lighter is one supplying materials for the repair of electrical instruments. There should be several such firms advertising in Work, but, unfortunately, there are only a few known to me who care to supply amateurs with small quantities of material. Among the few may be mentioned Mr. Caplatzi, 3, Chenies Street, Tottenham Court Road, who advertises in Work.—G. E. B.

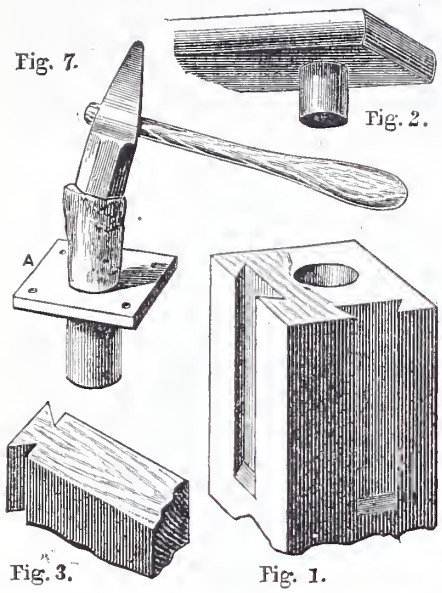
**Besoms.**—J. S. H. (*Cheetham*).—You should send this information through "Shop," addressed to the Editor of Work.

**Boot and Shoe Repairing.**—Rex.—Articles have appeared in Work, Nos. 112, 117, 122, 126, 130, and 137.

**Waste Products.**—Crede Signo.—No such paper as you allude to has appeared in Work.

**Capitaine Petroleum Engine.**—S. (*Stourbridge*).—No further information can be given respecting this engine than was accorded in the notice in Work to which you refer. We cannot give addresses in these notices.

**Table.**—W. S. (*Shipley*).—I will deal with your second query first. You can decide upon the table yourself. You do not say whether you require flaps to it; but by the absence of these particulars I presume that you want an article, the top of which shall be in one entire piece. The height of it should be about 28 in.; the legs (for a large table) turned from, at least, 2½ in. stuff; the length of their blocks depending upon the size of the table. The thickness of the top should be ⅝ in. or even 1 in., and the side-framing ¾ in. or ⅞ in. The method I am going to describe may not coincide with the views of all, but you can make a strong table by following it, with comparatively easy labour. Fig. 2 shows the under-side of one corner of the table. A hole should be there drilled to receive a stout dowel-pin (more than one dowel-pin can, of course, be used to each corner). The lower half of this dowel-pin will enter a hole down the leg-block, as shown in Fig. 1. This diagram also shows how to dovetail-mortise the sides of each block in order that the framing (Fig. 3) may be joined to them. To further strengthen the table, drive a number of screws through the inner side of the framing into the table-top, as in Fig. 6; or by driving them through small blocks as



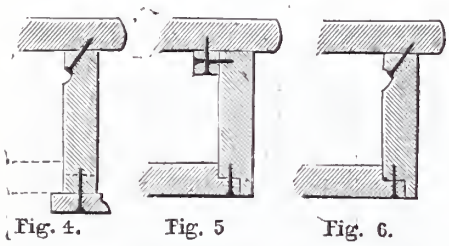


**Table. Fig. 1.—Leg-Block. Fig. 2.—Dowel fixed. Fig. 3.—Dovetail Tenon. Figs. 4, 5, and 6.—Various Sections of Sides. Fig. 7.—Dowel being formed—A, Dowel-Plate.**

in Fig. 5. For appearance' sake, you might screw moulded rails to the bottom of framing (Fig. 4). Across the table, connecting the framing, might be screwed stout rails, as shown by Figs. 5 and 6. If drawers are required, allowance must be made for their passage through the framing; and bearers should consist of rails screwed against the framing inside between the bottom rails. For drawer making, etc., read up your back numbers of WORK. Touching upon your first question, I must say you have done more than most do, when they ask two or more questions on different topics, by numbering your queries; but still it is a very essential matter, to ensure a satisfactory reply, that *each question* bearing on a different branch of trade or different trade *should be written on a separate sheet of paper*. How to sole a boot is rather out of my line of knowledge; but there is a member of our staff who gives instructions upon this trade; and to him would have been forwarded the boot query at the same time that the table question was placed in my hands if it had been on a separate sheet. You will not be surprised, therefore, at not seeing it replied to here; but our Editor, no doubt, will have forwarded it to our brother contributor, whose reply will appear in due course.—J. S.

**Bending Bamboo.**—E. McH. (*Hebburn-on-Tyne*).—Bamboo can be softened and bent either by dry heat, as over a lamp, or by heated steam. The subject is one which has often been brought forward in WORK. E. McH. is specially referred to Vol. I., p. 519, No. 33, and Vol. III., p. 252, No. 120. At the latter place may be seen a diagram of steaming apparatus. In Vol. I. is a series of articles on bamboo work.—M. M.

**Microphone Transmitter.**—G. C. H. (*New Kent Road*).—Write again, giving full particulars of microphone battery and receiver.—W. D.

**Bell Telephone.**—J. N. (*Perth*).—I have received your postcard. At present I am away from home, and cannot look up the answer to which you refer. I have not yet seen it, not having had the *pleasure* of reading WORK for the last few weeks.—W. D.

**Phonograph.**—PATIENCE.—I am sorry to say that I cannot give instructions for making a phonograph in "Shop" column, for the simple reason that space could not be spared for every detail. There is, however, an article in the Editor's hands upon this subject, which he will publish at his own convenience. Till then PATIENCE will have to wait.—W. D.

**Telephone.**—NO NAME.—The instructions from which you made your transmitter were doubtless all right, and the cause of the failure I am unable to fathom, inasmuch as you do not give sufficient particulars to help me. If you write again, explaining your instrument and the method which you have used for testing, I may be able to help you over your difficulty.—W. D.

**French Polishing.**—W. L. (*Oldham*).—Damp, rather than cold, was the cause of your polish peeling off; besides, you were very unwise in giving the handrails a coat of thick brush polish in the presence of so much damp. Paper it down again, putting a little linseed oil on the face of the glass-paper, and be content to work it up with the rubber. For this purpose, if possible, choose a bright, dry day; dissolve your shellac in naphtha instead of methylated spirits, and leave the work, if it looks well, in "dry shine"—*i.e.*, from the polish rubber; if, however, it must be spirited out, use naphtha. This may perchance make it necessary to use a little more oil, but be as sparing as possible with it. Do not overcharge your rubber with polish: in such a case as yours it would be best to use a little at a time, and work each rubber out fairly dry before re-charging, bearing in mind that friction, or, more properly speaking, "elbow grease," is a most important factor in gaining satisfactory results.—LIFEBOAT.

**Green Stain and Inlays.**—C. L. (*Beverley*).—I have several times in "Shop" advised the use of Tomlinson's aniline dyes, as sold at most druggists' in penny packets and threepenny tubes; also verdigris dissolved in hot vinegar. I can still recommend them, though since those replies were penned, I have received from Mr. H. C. Stephens, Aldersgate Street, London (a stain maker of high renown), specimens of a new green stain that appears to me to be very good, and is sold in sixpenny and shilling bottles. The coloured wood stringings and inlays are sold at most places where veneers and carvings are sold for cabinet makers (not saw-mills). I cannot give the addresses of any in your neighbourhood; but if you care to send a shilling postal order to Mr. Kingstone, veneer merchant, Pershore Street, Birmingham, or Mr. Harriss, veneer merchant, Bromsgrove Street, Birmingham, I have no doubt they will send you a variety you would be well satisfied with. Kingstone will undertake inlays to your own designs, if necessary. For the pearls (not shells) you might try Thomas Padmore, Edmund Street, Birmingham. But why not look in your local directory, and find dealers nearer home, where you could go and personally select what you require? I give you a wrinkle that may be of service to you: that well-selected and well-marked bird's-eye maple dyed green makes a capital imitation pearl inlay when well polished.—LIFEBOAT.

**Machine for Advertising.**—A. H. (*No Address*).—You say that the box has slots in it, so I suppose a card appears through each slot. If the cards appear and disappear at the same time, an arrangement similar to skeleton drawing, Fig. 1, might be used. I am assuming that the box in each case has four slots, and in Fig. 1 that the cards, A, rise and fall together, being fixed to a frame, *a*, fitted with two long bosses, *a'*, *a'*, through which holes are drilled vertically to fit guides, *b*, and with projections at side for links, *c*, *c*. The guides, *b*, can be fitted either to the top of the box or the bottom, as is most convenient. Two bell-crank levers, *d*, *d*, are pivoted at *e*, *e*, the upper end of each being fitted to link *c*, the other ends being connected together by coupling-rod *f*. The reciprocating motion is communicated to them by rod *g*, worked by crank *h*, which latter is fixed to shaft *i*, which is driven, in turn, by small cord-pulley, *j*, on outside of box, through cross-shaft, *k*, and bevel-wheels, *l*, *l*. If the pulley, *j*, is kept turning at a uniform speed, the cards, A, will remain slightly longer at the top and bottom of their travel than in the centre when rising or falling. The full lines show the positions of the levers, frame, etc., when the cards are raised, and the dotted lines when the cards are lowered. Another plan of obtaining the same motion would be to continue shaft *k*, Fig. 1, but now placed centrally under frame *a*, and provided with two cranks exactly under links, *c*, *c*, which links, in this case, must be turned into connecting-rods to grip the crank-pins, and as the cranks turn the frame, *a*, will rise and fall as before. As an alternative plan, suppose you want the two right-hand cards, Fig. 1, to rise together while the two left-hand ones fall: by dividing frame *a*, Fig. 1, in the centre, and reversing the left-hand bell-crank lever to position shown in Fig. 2, keeping the other gearing as it was, this will be secured. By conveying a reciprocating motion to the lower ends of bell-cranks, the upper end of one, together with the two cards, will rise, while the other one will fall. Thus the two pairs rise and fall alternately. The pairs need not be next each other; the first and third and second and fourth, or first and fourth and second and third, might be worked together by a slight variation in the mechanism. Still another method is shown in Figs. 3 and 3A, which illustrate a skeleton longitudinal section and an end elevation of crank-shaft, cranks, and connecting-rods. In this case the cards move alternatively, A being completely out of the box, A', A'' half out, and A''' hidden in box. In this case each card must be carried and worked separately, and have a separate guide and connecting-rod, the crank-shaft, *k*, in this case having four cranks at right angles. Thus you get each card rising and falling one after the other, no two cards being at the top or bottom at the same time. By means of cams instead of cranks, these cards might be made to rise and fall quickly, and remain still at the top of the stroke considerably longer than by the crank arrangement. The style of cam, Fig. 4, I have drawn to a larger scale than the others; *c* is the cam carried on shaft, *k*, and revolving with it; *a*, *a* are the guides for the cards; *d* is the rod to the top of which the card is fixed; while below, in contact with the cam, is a small wheel, *w*, to reduce the friction between the rod

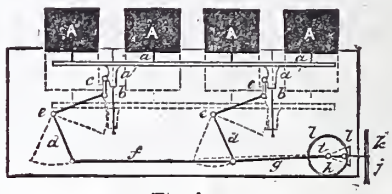

Fig. 1.

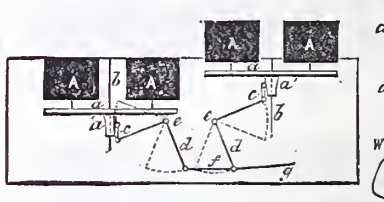

Fig. 2.

Fig. 4.

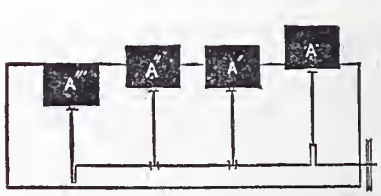

Fig 3.

Fig 3A.

**Machine for Advertising.**

and cam to a minimum. This shape of cam allows the card to remain stationary in its highest position for one-fifth of a revolution of shaft *k*, thus giving people a better chance of reading what there is on it than in the preceding cases. So if you arranged to have four cards, by setting the four cams at right angles to one another you would nearly always have one of the cards stationary for a short time. There are various methods of driving the mechanism shown in these drawings besides the outside pulley, which, however, if you have a shaft running near, is as convenient as any, and might easily be arranged out of sight of the public; there might also be used a small model steam or water engine. Inside the box you might use electricity or clock-work: which, I think, will prove the best. But the design of the mechanism and power to be used all depend on the size and number of the cards, so I cannot help you any more till these are given.—P. B. H.

**Saddlery.**—ANXIOUS.—J. Dixon & Sons' address is 24, Hall Lane, Walsall. *Saddlers' Gazette*, 46, Cannon Street, E.C. Monthly, 4d. The saddlers' and harness-makers' trade price list may help you to the lengths of parts. It gives the lengths of the stitching, and stitches to the inch, of every part of harness and saddlery, and trade prices; it costs 7d. J. Barlow & Co., Sedley Place, Oxford Street, W. Doubtless they can supply "Cutters' Lengths" publications, as they are a leading firm in London for all relating to harness and carriage furnishing, wholesale and retail.

**Measurements.**—DOBRA.—There is not the least doubt but that you would gather a vast deal of information from Cassell's "Technical Educator." It is published in monthly parts, but I should advise you to make inquiries, through your local bookseller, as to whether there is an edition being published now, etc. etc. You would also find Beaton's "Pocket Technical Guide, Measurer, and Estimator," published by Crosby Lockwood & Sons, 7, Stationers' Hall Court, London, E.C., very useful,

and, as the price is only 1s. 6d., I should certainly try it.—E. D.

**Model Horizontal Engine.**—F. C. (*Cardiff*) writes:—"I feel thankful for the answer *re* Model Horizontal Engine (see p. 572, No. 141), but what I should like to see is a dimensioned sketch of a model. I may say to F. C., who promised to further help me, that the cylinder I have hasn't got the ports cut in it yet."—[In reply, you do not give me the size of the port face on your casting, but I think I can supply information which will enable you to complete your work. Fig. 1 shows a side elevation of the proposed engine, with the cylinder in section; also a plan view of the connecting-rod, F. Fig. 2 is a longitudinal section of the steam and exhaust passages and the slide-valve. The block is too small to be clearly dimensioned, so I give you the measurements in letterpress. Make the piston, A, ¼ in. thick, and turn it to fit the cylinder truly; then no packing need be used. Face off the insides of the covers until the distance between them is increased from 2$\frac{1}{16}$ in. to 2¼ in.; you can then have a stroke of 1¾ in., with $\frac{1}{16}$ in. clearance at each end. The piston-rod, B, should be ¼ in. diameter, screwed at one end into the guide-block, D, and at the other into the piston, where its end may be lightly rivcted over, to prevent the piston from working loose. The gland, C, should be made to screw into the stuffing-box, which is to be lightly packed with cotton-yarn. The length of piston-rod you must find from your cylinder casting; it must be of such length that when the piston is against the bottom of the cylinder, and the gland, C, just free from the stuffing-box, the guide-block, D, clears easily from the gland. The guide-rods, E, E, should be of wire about $\frac{3}{32}$ in. (No. 13, B.W.G.) in diameter, screwed at one end into the cylinder cover as shown, the other ends to form a light driving fit to holes in a plate, T, fixed to the bedplate, M, and slotted out for the passage of the connecting-rod, F. Thickness of plate, T, $\frac{1}{16}$ in.; of bedplate, M, ¼ in. The connecting-rod, F, to be ¼ in. thick in the body, 3½ in. long between centres, and made with a forked end, R, to ride at one end on a pin, $\frac{1}{16}$ in. diameter, fixed in the guide-block, D, and at the other on a crank-pin, G, $\frac{3}{32}$ in. diameter.

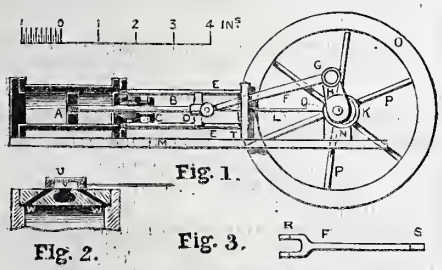

Fig. 1.

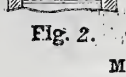

Fig. 2.

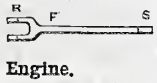

Fig. 3.

Model Horizontal Engine.

This pin is made with a head, and screwed into the crank, H, through the eye, S, of the connecting-rod. The crank, H, has a throw of $\frac{5}{8}$ in., is ⅜ in. thick, and is fixed on a main-shaft, I, ½ in. in diameter. This shaft is carried in ordinary bearings on pedestals, N, cast with or fixed on the bed-plate. The shaft carries a fly-wheel, O, 5½ in. outside diameter, with a rim ⅝ in. square in section, a boss, Q, ⅝ in. diameter by ⅜ in. thick, and six wire arms, P, ⅛ in. diameter (No. 11, B.W.G.). You may have a wheel cast complete, but the arms should then be wider; brass is the material to be used. On the shaft, I, is fixed an eccentric, K, with a throw of $\frac{5}{32}$ in., which, by a rod, L, drives the short slide-valve, U. The exhaust port, V, should be $\frac{3}{16}$ in. wide; space between exhaust and steam port, ½ in; steam ports, ½ in. wide each; edge of valve, $\frac{1}{16}$ in.; inside length of valve, ⅝ in.; the cylinder ends, W, of the steam ports, ½ in. wide. The length of the ports across the cylinder should be as great as the width of port face will allow. The depth of connecting-rod to be ⅛ in. at the forked end, and $\frac{3}{16}$ in. at the crank-pin end. The valve, U, to be covered by a steam chest, made to fit the port face. You may have to modify the valve sizes to fit your casting, but there should not be any difficulty in that. The rod L and the valve-rod may be made of wire, No. 16, B.W.G. It is preferable to use steel wire throughout. The crank, eccentric, and fly-wheels may be made driving fits to the main shaft.—F. C.]

**Designs for Work.**—J. A. (*Parsonstown*).—Your friend may send in his sofa design on approval. Indeed, I should be glad at all times to receive MSS. and designs from any reader of WORK who cares to submit to me, on approval, particulars of novelties or ideas which are his own work or idea.

**Incubator.**—W. B. (*Ramsey, Isle of Man*).—As several correspondents wish to know where to get fittings, I will try and arrange with someone to supply the whole. Watch advertisements in sale and exchange columns of WORK.—LEGHORN.

**Incubator.**—W. H. E. (*Crewe*).—See reply to W. B. above. Replies by post are against the rules.—LEGHORN.

**Thermometer.**—W. C. (*Wandsworth Road, S.W.*).—See reply to W. B. above.—LEGHORN.

**Incubator.**—F. W. M. (*Child's Hill*).—The "flower-pot" incubator was described and illustrated on p. 557, No. 35, Vol I. You may, however, as well try to hatch eggs on the hot-plate of a kitchen range as in such a contrivance. Why not make one as recently described in No. 143? If expense is an object, you might reduce size and make fittings of tin—tin canisters, for instance—although I am hound to say they will always be a trouble, rusting through in a very short time. I merely throw this out as a suggestion, because in building apparatus for actual work, it is better left alone altogether if it cannot be built properly.—LEGHORN.

**Incubator.**—H. H. (*Egham*).—Yours is a very good idea, but more applicable to a larger machine. The glass panels in lid are not very large, so that if you introduce two more rails, you will about do away with them altogether. You need not fear disturbing the regulator by opening and closing lid. Of course, on opening the lid, you disengage the regulator rod with the damper, but as the temperature then falls quickly, it is most probable that when the lid is closed again the regulator rod will be below the top of machine. The taper hole in lid allows a little play in this respect. If you prefer to follow your idea, you might make the centre rail narrower, cutting an oblong hole for ventilation, making the inner rails of lids narrower and hingeing them to the centre rail, screwing a small stop on to prevent them going back too far. If you adopt this plan, you will of course require to adapt the damper to suit the shape of the hole.—LEGHORN.

**Photos on Zinc.**—A SUBSCRIBER.—It is quite possible for anyone with the necessary skill to produce the work, but like many other things, it requires experience. We are not aware of any work published specially devoted to this subject. It is mostly in the hands of firms who make somewhat a secret of their processes. The zinc plates may be obtained of Dellagana & Co., Stereotypers, Shoe Lane, E.C.—D.

**Harmonium.**—G. E. L. (*Battersea*).—There is no useful purpose to be gained by adding stops to a portable harmonium. Probably there is only one set of reeds, or the makers would have adopted the very proper and obvious course of adding some way to control the various sets of reeds. If, as I surmise, only one set is present, the only useful stop would be that marked "expression," and the needful alteration to the instrument to add this stop would be greater than its value, and would render the instrument less portable. Fittings of every kind for musical instruments may be had of Messrs. Dawkins & Co., Charterhouse Street, Holborn Viaduct, or from advertisements in WORK.—B. A. B.

**Grip Lock Nut.**—A. D. (*Sheffield*).—Any stamped letter can be forwarded to the maker, but a free advertisement of his address cannot certainly be given in WORK.

**Water Engine.**—YOUNG ENGINEER.—Consult Glynn's "Water Power" in Weale's Rudimentary Series.

**Draught Screen.**—M. T. (*Pilrig, Edinburgh*).—For this, refer to No. 136 of WORK.

**Lathe Crank-Shaft on Points.**—J. H. (*Keighley*).—Surely you must have seen that this is the usual way of mounting the crank-shaft of a lathe. When you ask how they are lubricated you raise a smile. Put a drop of oil on the centre, just where it goes into the revolving shaft, and it will work its way in; don't pour half a pint, for that will only lubricate the floor. Some workmen seem to use as much as they can; and a nasty mess they make. Cranks for lathes are run usually on points, and I doubt whether any of the new plans are better: they are run on or between three friction rollers, and in bearings, but this requires a special bearing which can adjust itself to the shaft as it bends with the pressure of the foot on the treadle.—F. A. M.

**Hot-Air Engine.**—J. W. R. JR. (*Liverpool*).—I think you will get the information you need from my reply to another querist. I will only add to that, that as you wish to use yours for working a little pump, you can pass some of the water through the cooling cistern on the top of the heater. I should use a 2 in. or 3 in. working piston, and have a heater of twice the diameter, and the displacer same stroke as the piston; I think that would work a 1½ in. pump. I would not use any packing, but grind out the working cylinder and pump cylinder, and make the working piston of the same metal and same thickness as cylinder, so that heat may not interfere with fit.—F. A. M.

**Rocking-Horse.**—W. H. C. (*Leeds*).—This subject has not yet been treated; but the Editor has requested me to attend to it, and I will do my best to endeavour to place a page of designs and accompanying descriptive matter in the hands of the readers as soon as possible.—J. S.

**Etching.**—PROFESSIONAL.—I am hardly sure if I understand just what it is you wish to know; from the wording of your letter I take it you desire to know how to etch letters on glass, although I cannot understand why you have used a stencil. However, if this should not be what you want, write again. Cover the piece of flashed ruby with brunswick black; when dry, scrape away all of it from the parts of the glass you wish the acid to act upon. In your case it seems you wish the ground around the letters to be removed; you will therefore leave all the letters covered with the brunswick black. You ought to have no difficulty in getting the edges of the letters straight this way; you can use a square or straight-edge and a sharp point; if the other way (*i.e.*, the letters etched away), remove from the letters in the same way, and you can afterwards, if you wish, fill up with black. By acting upon the flashed side you can have white letters upon a ruby ground, or ruby letters upon a white ground, at pleasure.—W. E. D., JR.

**Silver Chloride Cell.**—ELECTRA.—The positive element in a silver chloride cell is zinc; the negative element is silver. The negative element is enclosed in some porous or bibulous material enveloping a paste made of silver chloride. This envelope may be blotting-paper or fine-mesh muslin. The positive element may be enveloped in a similar material charged with zinc chloride or with ammonia chloride, or may be suspended in a solution of either of these chlorides. The zinc should be in the form of a thick plate, as this element wears away. The silver may be in the form of sheet, foil, or wire. The electrolytic action of the cell reduces the silver chloride to pure silver, which is deposited on the negative element. You may use platinum foil as a substitute for silver foil if you choose to do so, but I do not see what advantage will be attained by the change, since the foil is soon coated with pure silver, and the electro-motive force of the cell is then that of the difference in potential between silver and zinc in an electrolyte of chlorine, not that of zinc and platinum.—G. E. B.

**Oak Work-Box.**—J. H. T. (*Earlsheaton*).—Without knowing the abilities of J. H. T., or what tools he possesses, it is difficult to advise, but such work-boxes as he can buy at the shops are made in pine, just like a packing-case (see Fig. 1). A rebate is made on all the angles except the bottom; this rebate is filled with hard wood like the box is to be

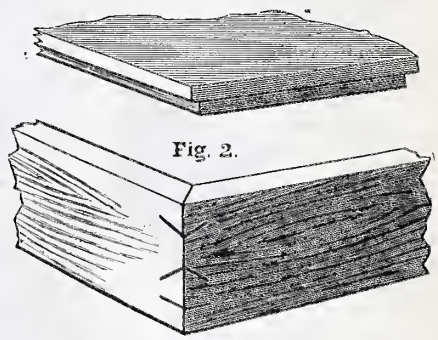

Fig. 2.

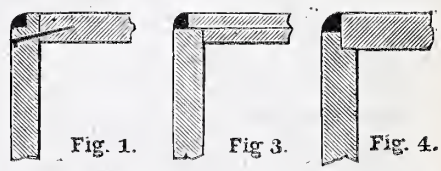

Fig. 1. Fig 3. Fig. 4.

**Oak Work-Box. Fig. 1.—Section of Corner of veneered Work-Box; the black quarter circle is hard Wood let in before the Veneer is laid. Fig. 2.—Box with mitred Angles, keyed, Top rebated, and end grain hidden by insertion. Fig. 3.—Section of Fig. 2 when completed. Fig. 4.—Section, if the Sides and Ends are rebated instead of Top. (Not drawn to scale.)**

veneered with. The ends, back and front, and top are then veneered, and the inserted hard wood just mentioned becomes available to make a nicely rounded corner. The box is then cut, thereby forming a lid, having its dimensions and figure of grain corresponding with the box itself. The edges of the cut surfaces are then veneered; hingeing, cleaning off, and the fixture of lock, escutcheon, etc., complete the box. This is the simplest way to make a work-box, but it is only available for veneered work. For solid wood, dovetailing is the best way, but if that is too difficult, I should mitre the sides and ends together, keying the joint with hard wood (see Fig. 2). In that case I should prepare a rebate for the top and bottom to rest in, and round the top insert a piece of hard wood as a finish, and to hide the end grain (see Fig. 4). Fig. 3 shows rebate on top.—B. A. B.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Upholstery.**—V. L. (*Bayswater*) writes:—"I should be obliged for some hints on upholstery, a branch of industry which I hope will soon be treated by your exceedingly useful journal. Should space not allow of an extensive article being devoted to the subject, I should be glad of the names of any good works on the subject."

**Address Wanted.**—TRANSPARLEUM writes:—"Will some reader of WORK please give me the present address of the Continental Novelty Company, late of 50, Leicester Square, London? The above was the address about four years ago."

**Saw.**—E. J. (*Borough, S.E.*) writes:—"Would W. W. (*Caverton*) oblige a brother reader by stating in 'Shop' what number or numbers in WORK I can find how to make a saw same as that of which parts are described in 'Shop,' No. 144, p. 637, Vol. III., in answer to TOP SAWYER?"

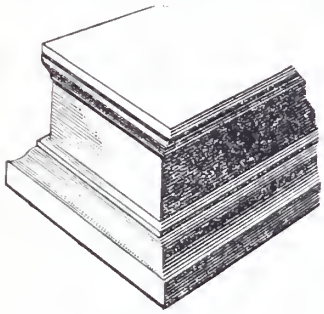
**Antique Furniture Designs.**—H. R. (*Kidderminster*) writes:—"I would be very glad to learn the price of, and where I could get, a book of patterns for carving antique furniture, such as old chests, wardrobes, cupboards, clock-cases, bookcases, and panels in other odd furniture—not necessarily in their full size, but large enough to sketch from to any size needed."

**Millboard Boxes.**—J. W. (*Upper Norwood*) writes:—"I shall be obliged if any reader would give me a description for making a hand machine or appliances for making small millboard boxes (5 in. × 1½ in. × 1 in.) in quantity—similar to those photo plates are packed in—in the columns of 'Shop.'"

**Wood.**—J. B. (*Birmingham*) writes:—"I wish to make a set of pigeon-holes with fifty-four compartments, but have a difficulty in obtaining the necessary wood. Could any reader of 'Shop' inform me where (close to Birmingham or West Bromwich preferred) I could get the wood, in pine or deal, planed and cut to the sizes I require, ready for putting together?"

**Tailoring.**—ANXIOUS writes:—"Can any reader of WORK inform me of a good teacher of cutting? Frock coats are my real difficulty."

**Lead Weights.**—W. W. W. (*Nottingham*) writes:—"Will some kind reader give me practical information as to the best way to mould lead weights such as a draughtsman uses, say ¾ in. long by 1¾ in. wide by 1¼ in. deep, having a mould on top and bottom, as per sketch? What metals, and in what proportion, should be added to the lead to have a hard and clean casting? Is it best to have a mould made in metal or in moulders, and to ensure a clear and perfect casting to prevent the use of the file? How to make the mould advised, if the weight is as per sketch?"



Lead Weight.

**Haag's Water Motor.**—B. J. (*King's Lynn*) writes:—"Can any reader of WORK give me a description of these motors?"

**Measuring Up.**—CEYLONESE (*Colombo*) writes:—"I would thank your readers for their views as to the best methods for me to measure up photographs and other perspective views of buildings, cylindrical figures, furniture, machinery, etc., each having one known dimension, and convert the same as far as practicable into working drawings."

**Working Drawings.**—CEYLONESE writes:—"I should be glad to learn, through 'Shop,' from whom I can obtain working drawings of bridges, cranes, furniture, etc."

**Octagonal Moorish Stool.** — ANGLO-DANE writes:—"Will some kind correspondent amongst the readers submit to the Editor a design for above, with colours, etc.? It is a very effective piece of furniture in a drawing-room, and quite within the scope of an amateur, I should say."

**Launch.**—E. G. (*Hereford*) writes:—"I have a flat-bottomed boat, built with pine and oak: it is 20 ft. long, 6 ft. wide, and 2 ft. 6 in. deep, and I wish to have it fitted up with steam engines and propellers—two ordinary slide-valve engines and two screw propellers. Would some kind reader let me know the size of engines and propellers? also whether two or three-blade propellers are best, as I wish the boat to travel as fast as possible, as I have some very rapid streams to pass over?"

**Wood for Carving.**—L. B. (*Hitchin*) asks for "the best shop in London to get lime-wood for carving on."

**Candle Making.**—G. N. (*Manchester*) writes:—"Could any reader tell me how to produce composite candles cheaply?—that is to say, could any reader describe to me through your columns which are the cheapest ingredients to use in composite candle making? I would, indeed, feel very thankful if you could do this for me, as I wish to try something in that line. I possess, of course, the proper moulds and wicks, only I should like to ascertain what best I could use so as to bring the article cheap and saleable."

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Besom Makers.**—J. W. W. (*Renshaw*) writes to L. S. D. (see p. 635, No. 144) that Joseph Jervis, Whaley, Clown, Chesterfield, is a besom maker.

**Mole Traps.**—T. J. (*Preston*) writes to J. J. (*Cumberland*) (see p. 492, No. 135):—"Respecting wooden mole trap with steel springs, I can recommend Mr. Joseph Cross, Tangier Street, Whitehaven, for a good article in that line."

**Flower-Pot Cases.**—F. H. (*Battersea*) writes, in reply to INQUIRER (see p. 621, No. 143):—"I do not know any firm where expansible flower-pot cases can be had. Eighteen years ago I supplied most of the West-End houses with them; but since the fashion for jars and Doulton ware, there has been no call for them. If INQUIRER thinks there is a sale for them, I should be pleased to be in communication with him."

**Wool-Winder.**—R. T. T. (*Frome*) writes, in reply to MART (see p. 621, No. 143):—"These are not hard to make; appended design explains itself. The base is made of wood, with a recess turned in it for lead to give stability; the pin is ¼ in. iron or steel wire 9 in. long, 1 in. screwing into wood stand, turned up smooth, with a shoulder at the foot shrunk on, or a piece of ⅜ in. rod can be turned down to ¼ in., leaving the shoulder. The shell is a piece of ¼ in. brass tubing, 6 in. long, with a knob screw in at the top to give a finished appearance. This tube must have its bottom edge turned true, as it runs on the shoulder mentioned above. A and B are two brass collars, 1 in. diameter; A is fixed, while B slides up and down, and is fixed by a set screw, C, in any desired position; the nearer it is brought to A, the larger the skein that can be held. The laths are wood, ⅜ in. wide, ⅛ in. thick, and 7 in. long, riveted

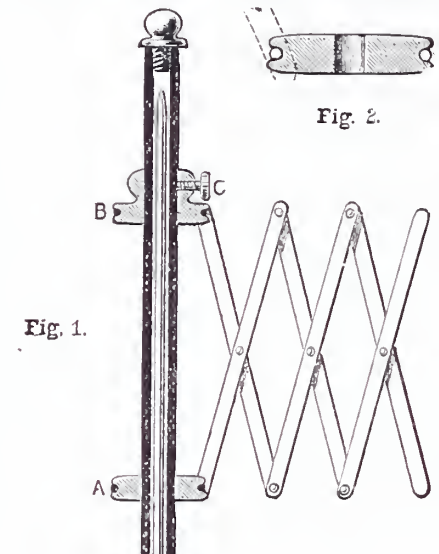


Fig. 1.

Fig. 2.

Wool-Winder and Parts.

to each other at the centres and ends. There are four sets, at right angles to each other, one only being shown in the sketch. The simplest way to fasten the laths to the collars is to turn a groove in the collar, as Fig. 2; cut four slots at right angles to each other, ⅛ in. wide by ¼ in. deep, into each of which one lath fits, as dotted line, Fig. 2, and a copper wire running in the groove, and passing through a hole in each lath, as shown, holds all tight, and yet allows the laths to turn as on a pivot. This size winder will hold any skein from 12 in. to 8 feet. As these make exceedingly popular Christmas presents to ladies, and can be easily made in numbers by anyone possessed of a lathe, I shall be pleased to write an article, giving detailed instructions and drawings, during next year, if the Editor wishes it."—[By all means submit this article on approval.—ED.]

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. R. S. (*Camberwell*); TELEPHONE; G. C. (*Woolwich*); A. S. ## FOUR HUNDRED POUNDS

**WORTH OF FRETWORK DESIGNS.**

J. H. SKINNER & CO. have now ready for delivery 8,000 of their Tenth Annual Catalogue of Fretwork, Carving, and Photographic Apparatus, including Designs, Fancy Woods, Treadle and Hand Machines, Frames, Saws, Drills, Planes, Carving Tools, Bevelled-edge Mirrors, Ornaments, Fasteners, and all other requisites; also Swiss and Chinese Wood Carvings, Magic Lanterns, Skates, Fancy Pocket Knives, and Scissors; Amateur Joiners' Benches and Tools; and their new **CELESTIAL ENAMEL** for decorating wood, glass, metal, earthenware, etc., the best and cheapest enamel in the market, including **54 different coloured specimens of the Enamel itself, beautifully mounted on a handsome recessed card** (this card alone is well worth the amount charged for Catalogue). The above described Catalogue of 60 pages quarto, with 600 illustrations beautifully lithographed, SENT POST FREE ON RECEIPT OF FOUR STAMPS. With each Catalogue we will include, **GRATIS, One Shillingsworth of Fretwork Designs,** selected by us from our stock. As each Catalogue costs us, with postage, only a fraction less than Sixpence, our customers will thus get in value ONE SHILLING AND SIXPENCE FOR FOURPENCE.

The Season being already so far advanced, we have decided to make this extraordinary offer, in order that our Catalogues may be distributed AT ONCE, trusting to the profit on future orders to recoup us for the loss on Catalogue.

**BEGINNER'S OUTFIT,** consisting of 12-in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient Planed Fretwood and Full Instructions, price 2s. 6d., post free. 6 ft. assorted Planed Fretwood, 2s. 6d.; 12 ft., 4s. 3d., post free. Book containing 12 sheets full-size designs, 1s. Good Fretsaws, 1s. 4d. per gross.

**J. H. SKINNER & CO., W Department, EAST DEREHAM.**

*Kindly mention this paper when ordering.*

## SMALL MODEL ELECTRO-MOTOR: SIMPLE AND EASY TO MAKE.

BY J. BROX.

INTRODUCTION—FIELD MAGNET—WINDING—ARMATURE—COMMUTATOR—BRUSHES—YOKE FOR ARMATURE—SHAFT BEARINGS—STAND, BLOCKS, ETC.—FIXING—FINAL REMARKS.

*Introduction.*—There are many who like to say, after they have made a model, "I made this all myself." This little model, it is hoped, will fulfil this remark as far as possible; there are no castings to be made, and for those who have no lathe, the whole can be made without any turning at all.

It is also within the reach of the younger branch who read this paper, who have any idea of using a few tools, and have a little ingenuity and patience about them. The little thing, when complete and judiciously picked out with such simple things as red sealing-wax varnish and brunswick black, looks a very presentable little article, to say nothing of its use in illustrating the laws of electro-magnetism. Last, but not least, it will go, and go well; this can be vouched for, as I have made one the exact counterpart of this. It can be driven by two small bichromate double carbon cells, or more, if you should be so disposed.

To dispense with any lathe work, the commutator is a little bit novel—at least, I don't remember having ever seen one like it; but that matters not as long as it works, and the words "no lathe" are fulfilled. I trust no one will think that I am against the use of a lathe, but there are so many who have not got one, that I think it may be a help to describe a motor where the use of one is not needed.

*Field Magnet.*—Get a piece of $\frac{3}{8}$ in. round wrought iron $4\frac{1}{2}$ in. long, as soft as possible, and bend it into the form of a horseshoe, with the ends $\frac{1}{2}$ in. apart on the inside; go over it with a file to take the rough off it, and then file up the two ends true and square one with the other. Cut a long strip of paper—newspaper does very well—$\frac{1}{4}$ in. wide, and paste it well, and wind it round the horse-shoe until there are three or so thicknesses on all over, except within $\frac{1}{2}$ in. from the ends; paste the outside all over, and go over it with your fingers to get it as even as you can; when this is dry give it a coat of brunswick black.

*Winding.*—As this magnet does not require any bobbins, we can go straight on with the winding. With some No. 28 silk-covered copper wire—don't use larger—begin winding, just short of the edge of the paper cover, with a half hitch, eaving about 6 in. tag; wind the wire on close and even until you come to the other end, just within the edge of the paper, then begin to go back—still winding the same way, of course—over the first coils, but mind it does not slip, or

that the second row does not sink down between the first.

When you have gone back about ¼ in. or so, hold the end tight, either by giving two or three turns on the opposite end or any other way you can think of, and give the whole magnet another coat of brunswick black; let this get dry (which does not take long), and go ahead again, doing the same when you get to the ends always, which you should turn one coil short each time; if you are careful in turning, and repeat the brunswick black, you will find that there is no slipping.

When you have made the winding, ⅝ in. about, more or less, in diameter all over, you can stop, finishing off the other end from which you began by tying a piece of thread close up to the finish, leaving another tag, 6 in. or so, and, winding the thread in different directions, and knotting, see that the flat ends are nice and bright, and put it away. (See Figs. 2, 3, and 4.)

*Armature.*—Take a small piece of soft wrought iron, 1⅝ in. long, ½ in., or a little more if you like, thick, and ⅜ in. wide; file it nice and smooth all over, and take off the edges on the sides; then get a short strip of paper, ⅜ in. wide, and paste it round the exact middle of the iron until you have three or four thicknesses on. Give the paper a coat of brunswick black, and let it dry.

Now begin to wind with fine wire: I used No. 36 silk-covered copper wire; take as much care as you can in winding the armature, turning backwards and forwards as with the field magnet, giving each layer a coat of brunswick black, and wind on as much as ever you can get; the more neatly you do it the more you will get on, and the better the results; finish off the same as the other magnet, which in this case will be in the middle, and don't forget the tags: each about 2 in. will do. You must see that your coils are not more than ¾ in. across in front, or the magnet will cut the armature coils. Fig. 8 will show what is meant. You can also, while you are winding the armature, try it in different positions against the magnet, and see that the armature coils are quite clear of everything, for if they touch nothing while the armature is against the magnet, you are quite safe after.

*Commutator.*—This part of the model is really nothing more than a two-part commutator, the only difference being that the brushes work on one face, and not on the rim. The reason this plan has been adopted is that you are supposed to have no lathe, and that to true up an even face on the flat is easier than on a round surface; in fact, the latter is next door to impossible without a lathe.

For the body of the commutator take any piece of hard wood about ¾ in. diameter (not less), and cut off, quite square, ⅝ in. of it. A piece of an old round ruler does very well indeed; true up both faces, and carefully drill a hole in the exact centre large enough to take tightly a good thick knitting-needle, 2½ in. of which will make you a very good steel shaft.

Out of a piece of sheet copper cut a disc, the size of the wooden body, and screw it on with four small wood screws, and countersink them (see Fig. 7). Cut the copper right through the centre with a file, and saw down through the wood for about ⅜ in.; the thickness of a saw cut (small) will be quite wide enough for the slits.

There is a proper angle at which to set out the slits, but in such a small model this is not necessary; but if you like to go so far, you will find the angles set out for you in Mr. Bonney's paper in WORK, Vol. II., No. 92, pages 643 and 644; you can apply the same rule for a flat surface as well as a round one.

Having gone so far, take off the two pieces of copper, mark them so that you can put them on again in the same way, and cut a nick out of the middle of each, as in Fig. 7, to prevent any chance of contact with the shaft; screw them on again, and glue into each side of the slot two neat little pieces of boxwood or bone, so that they stand just above the copper; then file up the whole face, bone strips, screw-heads, and all, to a true and even face as smooth as you can, and square to the shaft hole.

*Brushes.*—These are simply two thin copper strips, 3 in. long and $\frac{3}{16}$ in. wide, bent to the required shape, with a short piece of silk-covered copper wire about 6 in. long soldered to each, and having a small hole drilled at one end of each to take a small wood screw, as shown in Fig. 6.

*Yoke for Armature.*—Out of some brass sheet, $\frac{1}{16}$ in. thick or so, cut a piece 1⅝ in. long and ¼ in. wide, and bend it into the shape shown in Fig. 5, so that it will touch the ends of the armature and enclose the coils on that side; perhaps you may have to cut it a little longer: it all depends how much wire you managed to get on.

In the exact centre of this yoke drill a hole to fit the end of the steel shaft (your bit of knitting-needle), then carefully place the yoke on one side of the armature so that the hole for the shaft comes *exactly* in the centre of the armature and coils; tie this there with a bit of twine to prevent any chance of its loosing its position, and solder the two ends of the yoke to the two ends of the armature.

Now place your steel shaft into the hole in the yoke. see that it is perfectly perpendicular to the face of the armature, and solder it in, taking care not to drop any hot solder on to the armature coils. Don't forget that in fixing the shaft in there is not much chance of truing up afterwards, so try and get it plumb.

*Shaft Bearings.*—These are four pieces of brass cut from the same piece as the yoke, or a little thicker if you like; two about 1¼ in. by $\frac{3}{16}$ in., and two about ¾ in. by $\frac{3}{16}$ in., drilled, as shown in Figs. 5 and 9, to take four small wood screws each, and drilled to take the shaft. The best way to drill the shaft hole is to fix both pair of brasses on to any spare piece of wood just as they are to go on to the frame, only close together, side by side, and carefully drill right through both at once, square and true; then before you take them off mark them all, so that you may be sure of getting them to fit in their places when they are fixed.

*Stand, Blocks, etc.*—The stand and blocks you can make of any wood you like, and the form does not so much matter, except the top of the field magnet one, which should be made as shown in Figs. 2, 3, and 4.

The block for the shaft can be a simple square if you like; the only thing is, they must both be of such a height that the centre of the shaft is on a level with the centre line of the field magnet ends. You can glue them on the stand after you have set out their positions, or you can screw them on through the bottom of the stand, or you can do both. You will want four little binding screws for the stand, as in Fig. 1, which is a sketch of the model complete in its simplest form, but to no scale.

*Fixing.*—You can now slip the commutator on the shaft right up to the yoke, with its copper face away from it, and the line of the slits parallel with the length of the armature; if you drop a little strong glue in on each side, between the yoke and the wooden back of the commutator, you will find that it will hold it quite tight enough, especially if the shaft hole was not too large.

Now bring the ends of the coil, one on one side of the yoke, and the other on the other; cut them just long enough to reach the edge of the copper face of the commutator, but don't let them press against the yoke; bare the ends, and solder them to the rim, one to each segment, taking care that no solder runs on to the copper face.

Having fixed the field magnet in its seat, and screwed it tight by means of the button on top—previously having wound a little silk ribbon round the coils, to prevent the wood cutting them—you can then put the brass bearings on the other block in their proper places, the one farthest away from the magnets being flush with the side of the block, so that a little brass bush or washer can work against it. This is shown at B in Fig. 5, which must be soldered on to the shaft.

Then cut a small disc of stout lead, which you can easily do with a strong pair of steel compasses, solder this on the end of the shaft in such a place that it balances the armature, commutator, etc., and put it on true to prevent any "wobble." This little disc has two uses: it makes the model run easier by means of its balancing power, and also helps the armature over the two dead points.

Put your shaft, etc., on, and screw up the bearings; now unscrew the button of the field magnet, and adjust it so that the armature will run free, as near as you can get it, without any chance of touching. Then screw on the brushes, one on each side of the shaft, and between the bearings; mind they touch nothing but the wood; set the armature opposite the ends of the magnet, and bend the brushes so that the little bends at the other ends each press very gently on the wooden or bone strips of the commutator. The dotted lines in Fig. 7 show the position of the brushes, but you will find their best place when you set the model going.

You now bring the ends of the wires from the brushes to the two first binding screws, and the two ends of the field magnet coil to the other two. With four binding screws you can make all sorts of combinations with your battery: you can drive the model backwards or forwards, connect it in series or parallel, or any other combination you can think of.

*Final Remarks.*—I am sure, now, that if anyone follows these instructions with a little care, they will have a small model electro-motor, the only expense being the copper wire, four small binding screws, and some small wood screws; you can use almost any kind of wood for the stand, but, of course, a good close-grained wood makes the best job, and you can put into the work any degree of finish you like. All the rest of the stuff you could almost get out of an old scrap heap, such as the iron, odd bits of copper, brass, etc.

I have also endeavoured to use the least number of tools that I should think could turn out a small motor, and have kept my word about the lathe. I have also dispensed with any screwing tackle. Of course, there is the expense of your battery to drive your motor; but if I am allowed to do so, I will at some future time add a short paper to this showing how you can make your own battery, carbons and all, in the easiest and simplest way. But this will depend very much on the desire of readers of WORK to have such a paper as I have mentioned.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

HEN-AND-CHICKENS' COOPS: THE FRAMING—PUTTING TOGETHER—FOLDING MERIT—COMPANION BOARD—THE ENTRANCE—DOOR SUPPORT—PEA GUARDS: STAY-WIRES—THE ENDS—PEA HURDLES: THE MESH.

**Hen Coops.**—The manufacture of hen-and-chickens' coops is, in several wire-working establishments, a source of large profit; and this is hardly a truth to create wonder when it is remembered that the possession of fowls is a fact with so many householders and others.

The pattern shown in Fig. 185 represents the commonest kind of this class of goods, and it is my impression that it is one of the most useful for its special purpose. My amateur aspirants will find their progress a comparatively simple matter if anyone among them should decide to try his hand at making one of these articles—provided, of course, that he is fully acquainted with the practical details of "putting together," "turning over," etc., described in former numbers of WORK.

Why they are constructed of a greater width at the bottom than at the top I am not in a position to reply to satisfactorily; it certainly cannot be to allow the rain to escape when a shower envelops the articles, as is the reason for building sloping roofs to houses; for the most unintelligent of my readers will at once perceive that no resistance would be offered to the rain. The shape of the fowl, too, cannot be tendered as a reason, as I have always understood a fowl to be as wide at the top of its body as at its under part. Perhaps this is the reason: supposing that the articles were made of the same width at the bottom as at the top, the bird would have much less room to pick off the ground than it would, as in the present case, if the bottom were increased in width. If the coops were tall, then I should give it as my opinion that the bottoms were wider than the tops in order that there might exist less chance of them being toppled over. However, let it remain; but it is certainly true that as they are made now they demand the exercise of more troublesome labour than would otherwise be the case.

*The Framing.*—The top and two sides are usually of exactly the same size as each other in every respect, but the ends are generally an inch or so narrower at the tops than at the bottoms, as before remarked upon. The frames forming the top and the sides are of ordinary construction; each having two stay-bars secured to it, with knuckles inwards. The ends require some touching upon: thus, there are five separate frames.

It will be understood that the width of each side will exceed the depth of the ends, as the latter being wider at the bottom, the side rods thus formed are longer than they would be were they quite vertical; therefore the sides will each be in width equal to the length of a side rod in the ends.

*Putting Together.*—The top and sides are fastened together first, either by tying or binding. The latter operation consists of twisting a piece of thin wire several times around the bars of the frame where they come in contact with each other, thus embracing two bars or rods, as in Fig. 191. The binding wire must not encircle these bars too loosely, as in this event there would be a liability of a rickety job being constructed. Two or three bindings only will be necessary to keep all frames firmly together. Wherever one touches another, there it might be bound; although, as will be seen, it is really not necessary that more than four pairs of connections be used—or, more properly speaking, two at each of the four sides of the top frame, securing respectively the sides and ends of the article.

*Folding Merit.*—Wire-workers are in the habit of sending these coops home in a folded state, for obvious reasons; and it is sometimes bombastically claimed by dealers that these articles possess the advantage of being folded: from which customers might be led to suppose that they had been specially designed for the purpose of enabling the owners to stow them away in a small compass; whereas the truth is that the "obvious reasons" are the cause of them being so constructed. As a first reason, they are more conveniently made thus than they could be were the framework in one complete piece; and a second reason to adduce is that the makers themselves prefer that they shall fold, irrespective of this merit being advantageous to anyone else, in order that they may occupy less space while in transit to their buyers' warehouses.

When once rigged up, little necessity will arise for one of them to be folded, for in the event of an owner of many fowls possessing one or more, he will find continual use for one or all; and if a person owns but a few of these creatures, and requires only the occasional use of the coop, he can as well stow it away in its complete condition in the fowls' run or elsewhere, where it will be none the less liable to rust or spoil, or be a source of inconvenience, than would be the case were it in a folded state.

*Companion Board.*—These are sometimes secured to a board by means of staples driven over the bottom rods, and often they are merely stapled to the ground. Fig. 190 shows a board with staples for use in the former case. It is plainly apparent that a hen which chanced to occupy a coop which was merely stapled to the ground would run an extremely greater risk of catching some complaint from the damp of the space within which it were confined than would be the case if the coop were stapled to a board, when the dangers would be lessened, if not wholly avoided.

*The Entrance.*—At one end there will be a flap door. This is attached to a small frame, the latter of which is fitted on to the meshes, and the wires with which it comes in contact turned over on to it. The end of the coop in which the door is to be placed is at first in all respects the same as the opposite end, but the wires enclosed within the space to be occupied by the frame over which will hang the door must not be turned over, but left free, as in Fig. 186. When the remainder are turned over, the shears must be brought into action by cutting the necessary opening; the result being as in Fig. 187.

There it will be noticed that portion of those wires whose ends are shown protruding in the front of Fig. 186 are severed. It must be borne in mind that the area of the vacant space in Fig. 187 must be rather smaller than the area of the framing which will receive the door. This is in order to give allowance for sufficient length on the ends of the wires around the space to be turned over on to the frame. The frame to fit over this opening is made by bending a piece of wire, as shown in Fig. 188, and forming the ends into small hooks. The knuckles of these wires should be towards the inside of the work.

*The Door.*—The door is made by bending a wire in a similar manner to the small frame (Fig. 188), of a size large enough to hang conveniently over the latter. Fig. 189 shows the door. When it is fully completed it is fastened at the top of the small frame by having the hooks, which are shown, properly squeezed down.

*Door Support.*—The door can be kept open by numerous methods, one being that shown in Fig. 185. This is but the simple device of a short chain, with a hook attached to one end. The chain can be permanently fastened to either the door or the end proper of the coop, the hook being at the loose end—whichever may be the course adopted. If thought necessary, the door, when down, could be safely secured with a padlock, or for ordinary purposes a wire button would answer.

**Pea Guards.**—The articles which are made to protect those delicacies—peas—which are usually associated with other delicacies in the shape of lamb and young ducks, are called pea guards. In Fig. 192 one (or what some would term a portion of one) is shown. As most people may be aware, they are driven into the ground end to end, to cover that particular portion in which are the peas or their seeds, thereby being a preventative against the natural onslaughts of birds and other kinds of life. It is needless in such cases for the hideous scarecrow to despoil the view of human ken, when their eyes travel in that direction, under the plea, useless or otherwise, of frightening the timid but mischievous "dickies." The ends of the combined lengths are then enclosed with end frames (Fig. 193).

The original appearance of each guard is shown in Fig. 194. These frames contain two end rods, each projecting on either side to a distance of a few inches from the main portion of the work; and two side rods turned over on to the latter. The pieces of work secured to these frames are usually of the mesh represented in my diagrams, of which I speak more fully at the beginning of my papers on "Wire-Work"; but it must be obvious that there is no compulsion enacted as regards the particular pattern of the mesh used, as it may with equal efficiency be of the diamond class.

*Stay-Wires.*—The next operation is the fixing of stay-wires, which tend to strengthen a job, across a guard, as in Fig. 194, turning them over on to the frame, and tying them at their junctions in addition to at short intervals on the under wires. It will be noticed that there are four wires used in relation to my last remarks, each couple of which crosses each other, and have their ends either in direct contact with the end bars of the frame or with the opposite pair of stay-bars. They are then bent around a cylindrical surface.

*The Ends.*—One end of a pea guard is represented in Fig. 193. It is simply a rod bent half-circular in shape, fastened to a straight one, the latter of which extends at each side beyond the ends of the former, with a piece of work turned over on to them. When they are joined to the main part of the guard, one projection is passed through the guard at one corner from the inside, and the other end through the opposite corner, when they are then bent round towards the front of the end, and finally squeezed flat up against it, the straight rod thus being in reality doubled upon itself, and all superfluous material clipped off. For further security they are tied here and there round the bent portion to the guard frame.

It is not such a difficult task as it may at first sight appear to fasten an end to the

adjacent portions of a guard, and no illustrations nor further written details will be in any way helpful.

The projections at the ends of the rods on the main frame are, as lately told, for the purpose of enabling the guard to be fixed to the earth. It must be apparent that when the article is bent these points are protruding downwards.

It is usual to supply two ends with every dozen of the individual guards, but, of course, personal requirements may demand even more ends to such a number, or may be less.

Pea Hurdles.—Pea hurdles, as perhaps all are aware, are used as guides and supports for the plants when they show above ground. One is shown in Fig. 195. It is usual, I believe, to drive stakes deeply into the ground, at distances apart equal to the separate lengths of the hurdles, allowing a sufficiently long portion of each to protrude to nearly the height of a hurdle, and to attach to them the ends of the various couples of hurdles which meet at those points when placed in a row consecutively. The side rods of these articles might be carried in length to an extent of several inches beyond the bottom bar of each; but so secure and firm a hold is not to be obtained by these means as by driving stakes into the soil at various points, as is customarily done. Again, if merely the extended side rods are adopted, each hurdle will have to be bound to the next one at the end which touches it, thereby necessitating equally as

much labour as would be entailed by fastening them to stakes.

*The Mesh.*—A small mesh is not required for such articles as are receiving attention; therefore it is needless to use more material than is essential to obtaining the necessary strength. As this is the case, crimped or corrugated wire may or may not be used, although it is far preferable, on many accounts, to use perfectly straight stuff, and tie it at its various junctions, as in the manner shown in my introductory remarks in my first paper on Wire-work (Vol. III., No. 105, page 8).

For the frame five rods will be required. It is preferable to have the shorter (*i.e.*, the end and middle) ones with forged or flattened ends. This can be understood from Figs. 197 and 198. The longer rods are severed at points flush with the outsides of the ends of the work when completed, over which ends are squeezed the flattened parts of the end rods, while the ends of the middle rods are also turned over them in a similar manner, in contrast to the method shown in Fig. 199 in relation to hen-and-chickens' coops.

The wires in this instance will be turned over on to the frame in precisely the same way as they are in any and every other case.

With this I must bring my instructions on Wire-work to a close. I am obliged to leave much unsaid that might be said, but I have no more space at my command, and I am therefore reluctantly compelled to take leave of my readers at this point.

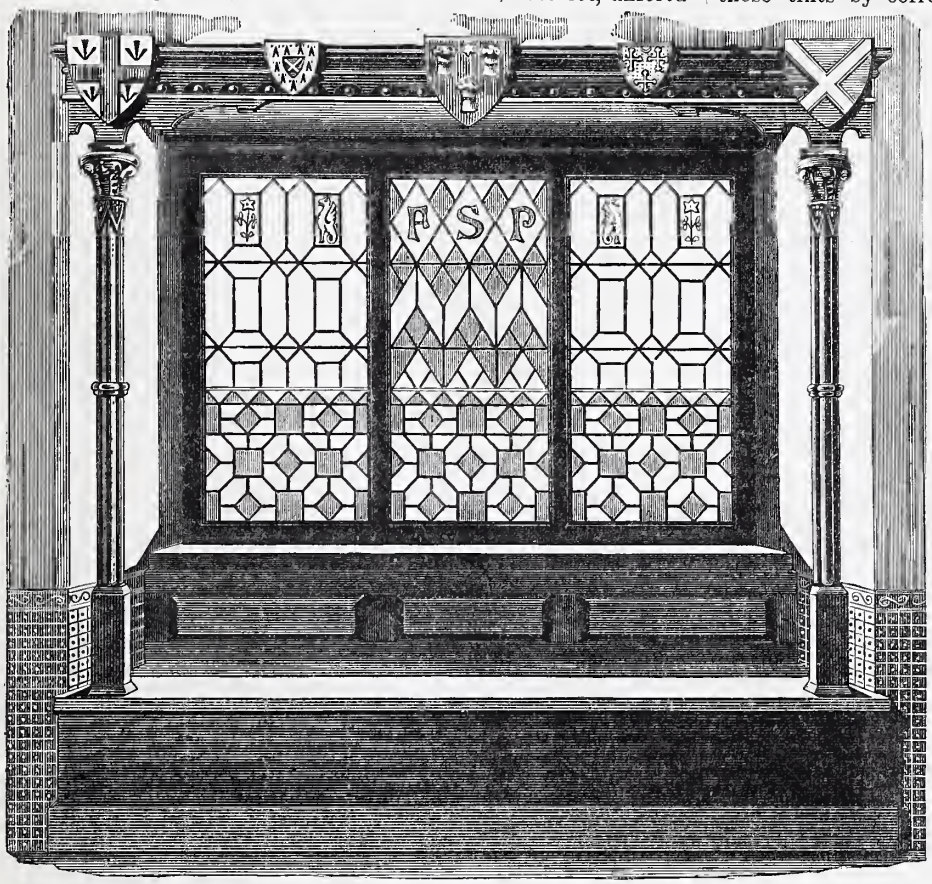

Fig. 19.—Window of Dining-Room.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

THE DINING-ROOM: THE WINDOW—THE WINDOW CORNICE—THE CORNICE ROUND CEILING—PAINTING AND PAPERING—CONCLUSION.

*The Dining-Room: The Window.*—This room had but a single window, but it was of such a size as to admit abundance of light. It had originally been divided into three lights by handsomely wrought stone mullions, but these had disappeared, and square wooden uprights, 2 in. wide, had taken their places. They were in the right situations, so I did not remove them as I had those in the study, but used them on the centres of the handsome mullions which appear in the illustration (Fig. 19). The leaded lights were of much the same character as those in the study, and by no means worth preserving. I proposed to put in new ones, and, as I was not now compelled to economise every ray of daylight, I indulged in more ornamental glass than in the former room.

This window looked directly into the village street, and it was desirable that the glass in its lower portion should form a screen. In designing my lights, therefore, I arranged that the lower third should be entirely in coloured cathedral glass, but of a very low and quiet tone—the prevailing tint being green, varied with faint reds and yellows. No glaring colour was admitted. The illustration in which I can convey the arrangement of the lead lines, and merely hint at variations in tone, does not, unfortunately, enable me to show the pleasing effect of colour produced.

As regards the two outside lights, their upper two-thirds were of plain white glass, except the two plaques bearing heraldic badges near the top. These plaques were of white cathedral, the charges on them drawn in brown matting colour, and the background, or "field," washed in with gold-stain.

In the central light, as is indicated, the plain white glass is arranged in combination with low-toned coloured glass of the same kind and tints as below; and instead of the plaques at top I introduced panes bearing my initials, brought out in the same manner with gold-stain.

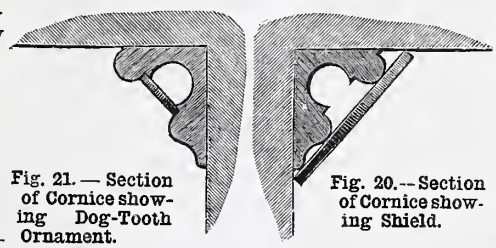

Fig. 21.—Section of Cornice showing Dog-Tooth Ornament.

Fig. 20.—Section of Cornice showing Shield.

This window is about 6 ft. broad by 3½ ft. high. The leaded lights, with ties, bars, etc., all ready for fixing, cost me, if I remember rightly, about 45s. I fixed them myself. I took the precaution to draw a full-sized cartoon of the lead lines of the central and of one of the side lights, for the guidance of the workman. Also I drew out to full size on tracing paper the initials and one of each of the badges (the wyvern and the columbine) for the use of the glass-painter. For the tinted portion I selected patterns of the glass, numbered them, and indicated all such panes as were to be of those tints by corresponding numbers on the cartoon. All possibility of mistakes in colour was thus guarded against. The subdued and harmonious effect of this window has, I think, been praised by all judges in matters of taste who have seen it. The only positive colour contained in it—if that can so be called—is the gold ground of the plaques, etc. There are no strong reds or greens, and no blue whatever.

*The Window Cornice.*—The opening to this window was bare and ugly, there being no woodwork round it. Most persons would, I suppose, have masked it by a large curtain pole and heavy curtains; but this would not have agreed with my scheme of decoration. The illustration (Fig. 19) gives a fair idea of the plan adopted. The carved pillars which flank it are the footposts of that same demolished four-post bedstead of the old school of which mention has already been made on more than one occasion. They have clustered shafts, and are beautifully carved in dark mahogany, in the style of a hundred years since. The complete bedstead cost me, at an auction sale, 20s. These pillars were indeed so good in their way that I was glad to bring them into a position where they would be more seen than in a bedroom. The cornice itself is of ebonised pine; the shields which decorate it are emblazoned in their proper heraldic tinctures.

*The Ceiling Cornice.*—The upper portion of this window cornice is of the same moulding as that used over the door in the hall; in the present case it is continued as a ceiling cornice round the entire room. It is seen in section in Figs. 20 and 21. Its projection is 2 in., and its depth may be slightly more. It has an effective hollow in its middle. By the hundred feet run it cost me, I think, about 23s. 6d. Of course, I had to ebonise and polish it myself. Having fixed it round the room, I attached to it a series of shields, as in the section, Fig. 20. They were of the same size as the smaller ones on the window cornice (Fig. 19), namely, 5½ in. high. They were cut from

½ in. pine board, and emblazoned with proper heraldic tinctures, their sides being ebonised like the moulding on which they lie. At the corners of the room the upper portions of the shields touch; at other places there is a space of about 2 ft. between each two shields, and in the centre of this space is a square dog-tooth ornament, cut from ¼ in. pine and gilded. How this is arranged is seen in section in Fig. 21. Thus the shields and ornaments alternate.

Being something of the genealogist and herald, I charged these shields with the arms of as many different families as I have reasons for supposing to be connected with my own, by blood or marriage. They thus form a sort of family history in brief, as well as tending to brighten up my walls with their gilding and brilliant colours.

*Painting and Papering.*—The skirting boards, the door frames and architraves, and the doors themselves, their panels only excepted, I painted of a dead black; the panels I coloured of a deep Pompeian red. Much the same system of colouring was also adopted throughout the hall and study. I am much of Mr. Ruskin's opinion as to the superior artistic effect of self-colours over graining, if arranged with judgment. Certainly for the amateur they are much to be preferred. Anyone of ordinary intelligence can soon pick up the knack of laying on self-colours properly, whereas graining demands very considerable skill. There is no graining in my house. The papers used on my dining-room walls were such as showed only different shades of brown.

At this point I may fairly bring my remarks on this subject to a close, having brought under the reader's notice the most prominent of the various steps I took in "making the best of a bad house," or, in other words, what I did to convert bald, bare-looking, and unpromising premises into a place which at least had the merit of satisfying the eye, even of a hypercritical observer, in general arrangement, form, and colour.

## COPYRIGHT IN SCULPTURE.

BY CHARLES KELSEY.

INTRODUCTION—THE SCULPTURE COPYRIGHT ACT—DEFINITION OF SCULPTURE—WORKS MUST BE ORIGINAL—HOW TO SECURE COPYRIGHT—DEFINITION OF PUBLICATION—DURATION OF COPYRIGHT—ACTION FOR OFFENCES—CONCLUSION.

*Introduction.*—This paper is written as a sequel to the articles on the Registration of Designs, which have recently appeared in WORK. It was noted in those articles that sculpture was expressly excluded from the operation of the Act which governs the registration of designs; and as in some cases—such, for instance, as small statuettes—it is difficult, when protection is required, to decide which is the better course to pursue, this brief statement of the law as to sculpture copyright has been written.

*The Sculpture Copyright Act.*—Copyright in sculpture is governed and regulated by the provisions of the Act of Parliament known as the 54 Geo. III., cap. 56.

This Act was passed in A.D. 1814, taking the place of an older Act (38 Geo. III., cap. 71) passed in A.D. 1798, which was found faulty in practice and required amendment.

This existing Act, then, must be examined for information and guidance.

*Definition of Sculpture.*—The first point to determine is the definition, for copyright purposes, of the term "sculpture."

The term, as generally used, means statues and the like, carved in marble or stone. Cast statues in bronze and similar metals, carvings or castings in alto- and basso-relievo, are also included. The Act covers all these, and also takes in other things which are not now usually considered as being sculpture.

The term "sculpture," for the purposes of this Act, includes:—

Sculptures, models, copies, or casts of the human figure, whether treated singly or in groups, whether nude or draped, combined with animals or otherwise. Also portions of the human figure, including busts.

Also sculptures, models, copies, or casts of animals, or portions of animals, whether treated singly or in groups, in combination with the human figure or otherwise.

Also any carvings or castings, or models in alto- or basso-relievo—*i.e.*, high or low relief—and any other subject, being matter of invention in sculpture.

Also casts taken from Nature—such as casts of the human figure, or animals, or portions of either of them, and casts taken from any other natural object.

This definition is wide enough to cover works in marble, stone, plaster, metal, wood, ivory, bone, pottery, terra-cotta, earthenware, clay, wax, or any other material in which such works can be, or usually are, executed.

*Works must be Original.*—It should be noted that these works, to be entitled to protection, must be "new or original," meaning, evidently, thereby the original emanations of the brain and art of the sculptor, and not mere copies taken from previously existing works.

In my first paper on the Registration of Designs (Vol. III., p. 564), I dealt with the same terms, which appear also in that Act, and those remarks may usefully be referred to, as further illustrative of this point.

*How to secure the Copyright.*—The process of securing the copyright in any such work is a very simple one. No registration or payment of fees, as is the case in designs, is required; the sculptor is only required to put upon all and every such sculpture, model, cast, etc., issued by him, his name or names, and the date of publication.

*Definition of Publication.*—"Date of publication" would appear to be the date on which such sculpture is issued, sold, or exhibited in public. It does not necessarily mean the date of completion of the work, for it may remain in the private studio of the sculptor for a considerable time before it is exhibited to the public. This same term has been dealt with in the papers relating to designs, previously mentioned; and in the case of designs the term "publication" has been held to include such an act as showing it to persons for the purpose of securing orders. Probably a similar meaning would be held to apply to the term as used in reference to sculpture.

*Duration of Copyright.*—The copyright so acquired lasts for a period of fourteen years from the date of publication; during that period the sole right and property in such a work is vested in the proprietor. He can sell, or assign, this right to any other person at his pleasure.

If the original sculptor is still living at the expiration of the first term of fourteen years, a further term of copyright for another fourteen years is vested in him. If he is dead at the expiration of the first term, the private copyright ceases, and it becomes public property.

*Actions for Offences.*—The Act also says that any action for any offence against this Act must be brought within the period of six months next after the discovery of such offence, and not afterwards.

*Conclusion.*—Such, in brief, are the provisions of the law regulating copyright in sculpture; and this information will be interesting and valuable to those readers of WORK who practise the arts of carving, modelling, and plaster-cast making, as showing them how to secure copyright in their works.

## AN ANTIQUE DUTCH CHAIR.

BY REX MAGNUS.

IN the tumble-down hut at Zaandam, in Holland, which is shown to tourists as the resting-place of Peter the Great, while resident in that town for the purpose of learning the "schipmaaker's geschaft," there is no furniture to be seen other than a table and two or three old chairs. These latter are of little artistic merit, but are eminently quaint, and, in the opinion of the writer, are very suggestive to the amateur cabinet-maker, offering great scope for amplification or ornamentation. Fig. 1 shows the general

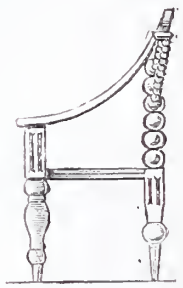

Fig. 3.

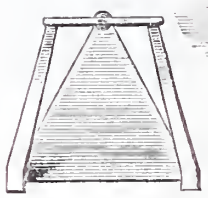

Fig. 2.

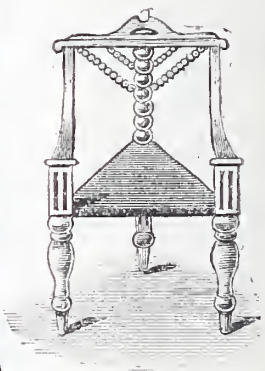

Fig. 1.

**Fig. 1.—Dutch Chair of Sixteenth Century. Fig. 2.—Plan. Fig. 3.—Side Elevation.**

construction of such chairs, but as it is drawn from memory, is probably inexact as to the turnings of the legs, which look like anachronisms. Still, there is nothing to prevent the would-be maker from selecting his own particular form of leg—probably the plainer and severer, the more "in keeping" the result would be. Oak, of course, would be the wood to use if one had the choice, but beech or elm would look equally well when stained up and polished. In the originals the seats are simply triangular boards, without the least attempt to "shape," as in modern wooden seats. But a very handsome article of furniture might be made by padding the seat and upholstering in leather. In the originals the workmanship also is as crude as the accompanying drawings, which I hope will be sufficient of a guide to anyone attempting to make it. Instead of adhering slavishly to conventional models, amateurs should study the Swedish, Norwegian, or Danish designs in common use for tables, chairs, stools, etc.,

all of which will be found well worthy of attention. It is surprising that our technical journals provide us with so few such, as they are, for the most part, easy of construction, while admitting of any amount of ornamentation.

## AN EASILY-MADE CHEST OF DRAWERS.

BY DAVID DENNING.

UTILITY—ORIGINATION OF NAME—SIZE—MATERIAL — ENDS — TOP BEARERS — BOTTOM — DRAWER BEARERS — RUNNERS — GUIDE — DRAWER SIDES—FRONTS—BACKS—BOTTOMS — MOULDINGS.

As a receptacle for stowing away not only clothes but sundry articles of all kinds, it may be questioned whether any piece of furniture is so generally popular and convenient as what is known as a "chest" of drawers. Even in the wardrobe—which, when of large size, to a certain extent supersedes this useful piece of furniture—a considerable portion is generally devoted to what may be called an enclosed chest of drawers.

As an explanation of a combination of drawers being termed a chest, it may be interesting to note that, as is no doubt well known to the majority of readers, what is generally understood as a chest—*i.e.*, a box—has only a lid to close the top. Chests, of which many old specimens are still extant, at one time formed the storing accommodation for clothes, etc. These old specimens generally stand on legs. Well, by degrees it became customary to put a drawer, or drawers, under the box bottom—the convenience of a drawer, especially when shallow, being, no doubt, readily recognised. The next development was to have two tiers or rows of drawers, with what was, to all intents, the old-fashioned chest with lid above them. By degrees the chest contained nothing but drawers—the lid was done away with. The old title of a chest of drawers has stuck to the modern article, however, and probably at the present time there is no one in Great Britain or the sister island who is unfamiliar with it.

Instead of being a chest, the outer part—that in which the drawers are enclosed—is rather a cupboard without doors, and with rails on which the drawers fit; and if the young or inexperienced maker will bear this in mind, I think some of his difficulties in devising elaborations of a simple chest of drawers will be lessened. It is, however, not my intention now to explain the construction of anything but a simple chest of drawers, and that, too, in the simplest manner, so that anyone almost may undertake it, even though he has little or no skill in drawer work.

However simple in theory and easy to the expert, every novice who has tried it knows that a considerable amount of care and accurate workmanship are wanted. The dovetailing bothers him especially.

Now, I intend to show those who, for any reason, do not want to make drawers in the usual way how they may make a good, useful chest, without more than a very small amount of skill and with few tools, by a very easy method.

The size I must leave to the convenience of the maker, but it may be said that a "four foot" is usually regarded as the standard, and the arrangement shown in Fig. 1 is the ordinary one.

It may be assumed that pine, or American white-wood, which is now obtainable occasionally at about the same price, will be the material, and the only thing which it may be necessary to mention is that, if pine be chosen, it should be free from knots. The other seldom has any.

It stands to reason that the first thing the maker has to do is to decide on the size of the chest, and general arrangement of the drawers. He will then be able to joint up, if necessary, to get the requisite width of plank for the top and ends. The thickness of stuff for these parts, it may be assumed, will be 1 in. Less might be managed with, but then it would be almost impossible to dispense with lining up, and this would entail not only more labour, but would require greater skill.

In actual construction the first proceeding will be to connect the two end pieces. This may be done by nailing the top and bottom direct to them; but if such rough-and-ready joinery will do for any reader, I may as well say that he surely can hardly require directions. It will be better to take a little more trouble and do the thing properly by connecting the ends with bearers, at any rate at the top. The top, or cover, will then be fastened to them. The bottom ends may be treated in the same way, but very little more skill will be required to fit in a solid bottom.

For the top bearers two pieces at least should be used: one at the back, and the other in front. A good deal depends on the width of these pieces, as well as on the width of the chest, whether one more, in the centre, will not be advisable. They should not be less than 3 in. wide, while if they are a good deal more it will not do any harm; for their purpose is to rigidly connect the ends, as well as form a vehicle to which the top is fixed. In thickness they should not be less than 1 in. stuff.

The ordinary way of fixing these would be to lap dovetail them in, but it will be sufficient to sink them into the ends. To manage this, mark their thickness on the inner side of the ends, measuring from the top edge. Then cut away, say, half, or a little more, of the thickness of the ends down to this gauged line for a sufficient space to allow the ends of the bearers to lie within them, with the upper surfaces of the bearers and the top edges of the ends exactly flush.

The front edge of the front bearer must also be flush with the front edges of the ends. That this may be managed without the unsightliness which would be caused by the bearer showing through into the ends, cut a short distance back on the ends of the bearer, making them narrower where they fit into the spaces cut for them, as represented in Fig. 2. The back bearer may as well be set entirely about ½ in. within the ends—*i.e.*, these will project that distance beyond its hinder edge, thus affording supports for the top ends of the backing to be fixed on afterwards.

The bottom may be made in the same way, but it will be almost better to make it solid. A little more material will be required in this case, but then there will not be the labour of fixing runners for the bottom drawers. To fasten the solid bottom in, it is only necessary to cut two or three tenons on it, as in Fig. 3, and corresponding sockets as at top for them.

Naturally, this form of construction does not bind the ends so securely as dovetails would, but then the requisite degree of strength can be got easily by the use of glue and nails. The former, of course, does not hold well on end grains, but still, if properly used, it has some power. The nails—nothing is better for the purpose than the ordinary French or wire nails—should be of a good length—say, 2 in. or 2½ in.—and be driven in slanting in opposite directions.

Before the parts referred to can be fixed finally, it will, however, be necessary to arrange and fasten the pieces on which the drawers run. These pieces are the bearers between the drawers, and by which they are supported in front, and the runners extending from back to front for the edges of the drawer sides to slide against. The bottom drawer, of course, requires neither bearer nor runners below it, as the solid bottom serves for both.

The other bearers should be the same thickness as already mentioned, and it will be noted that they are required in front only. They must be cut back like the top front bearer, and sunk into mortises, or holes, prepared for them in the ends. A nail into each, driven in slantingly from the back edge, should hold them secure enough; for, being tenoned in, they will support any weight the drawers will hold. If, however, the mortises are too large, and the tenons obviously fit too loosely, these may be fastened tightly in by what is called "foxing" them. To do this, slightly split the ends of the bearers, and insert a small wedge or two part way. As the tenon is forced home the wedge will be driven further into the split, and consequently force the inner edges of the tenon wider apart, and cause a tight fit.

The runners now demand attention. They should be of exactly the same substance as the bearers, so that both on the upper and under surfaces they may be flush. It will also be necessary to see that they are fitted square across; for if all, or any of them, incline upwards or downwards, the drawers themselves—however well-made they may be—will be sure to fit badly. The width of the runners may be anything, but in this case it will not be necessary for them to be more than an inch, while narrower—anything not less than the thickness of the drawer side—might suffice. There is, however, no object in having them as narrow as they might be. Now, to glue them on to the ends may seem to the novice an easy way of fastening them, and, so far as the actual fixing is concerned, it might be satisfactory enough; but the result probably would be to cause the ends to split by interfering with the natural play of the wood. To go into the reasons for this would require too much space, and it must suffice to say that the ends must on no account be bound, as they would be were the runners to be glued along their entire length. It will be better to dispense with glue entirely for them; but if any is considered necessary, let it be just a touch at their front ends. One or two nails driven straight through, though, about the same place, will be sufficient, unless the drawers have to contain an unusual weight, and, in any case, screws will probably suffice. The hinder end of the runners should be fastened by one nail, driven in part way only, on the slant from behind, as shown in Fig. 4. By this means the end is allowed to contract without splitting.

The upright fitting between the two top drawers is so simple that it is unnecessary to explain it in detail. There must be another runner behind it, and this runner, having to support two drawer sides, must be wider than the others.

To prevent these drawers "wobbling" sideways, a guide must be fixed on the runner of exactly the thickness of the upright. It may be either glued or nailed on.

The main portion of the carcase being ready, the top may be fastened on at any time. It will be fastened on by a few screws, driven in through the top bearers, and should hardly be less than of 1 in. stuff. The carcase will either be fastened on to a plinth—which is nothing more than a frame of, say, 4 in. in depth of 1 in. stuff—or, as is often done, on turned stumps.

The construction of the drawers may seem the most formidable portion of the work, but little difficulty will occur if the following method be adopted. Dovetailing will be dispensed with, and nails be used instead.

The drawer sides—of thin, say ½ in., stuff—should be got out first, and each be accurately fitted to the place it is ultimately to occupy. To prevent mistakes, they should all be marked to show what part they are intended for, as it will be very accurate workmanship if they are all of exactly the same size, and consequently interchangeable.

The drawer fronts of 1 in. stuff, instead of, as is usual with dovetailed joints, occupying the whole of each opening, must be shorter by the thickness of the two sides, for these are to be nailed on to the ends of the front. To nail the front on to the sides would be very bad joinery; for instead of pulling the drawer out when wanted, the front would very likely come away. An easy way of fitting the fronts will be to place the sides in position in the job, thus giving the exact size to which the fronts should be cut. It may be well to note that at this stage no attempt should be made to give the drawers an easy fit. On the contrary, all the parts should fit very tightly, as the completed drawer can be subsequently sufficiently eased with glass-paper, or even, if necessary, by having a shaving or two removed by the plane. If made easy fitting at first, they will probably be too loose afterwards.

The drawer backs will be of the same length as the fronts, but it is usual for them to be narrower, not only to allow of the bottoms being under them, but to be a little lower at the top than the sides are. Like the front, the sides will be nailed on to them.

Before fixing these parts together, the drawer bottom fittings should be attended to. The bottoms might be nailed on, but a far better way will be to devote a little more time, and proceed in a more workmanlike manner. Those who have a plough plane may prefer to make the usual slips for fitting the bottom into; but for the benefit of others another arrangement, which answers exactly the same purpose, is given as follows: Glue a square strip of wood — say ¼ in. square—on the inner face of each side, close to the lower edge, and extending from the inside of the front to the back. Above each strip, leaving a sufficient space for the thickness of the bottom, glue another. Between the two there will thus be a kind of groove, within which the bottom will be held. It may be glued to the drawer front, though it will be preferable to have a similar groove there, too, but on no account use glue in the groove or anywhere else. The drawer back fits above the bottom, which should be left projecting ½ in. or so. If necessary a brad, or, far better, a screw, may be driven into the back through the bottom, though, if this is glued in front, there will be great risk of its splitting as it contracts.

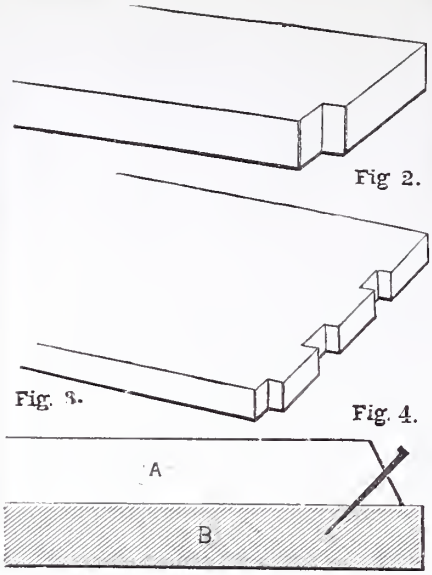

Fig. 2.—End of Bearer. Fig. 3.—End of Batten. Fig. 4.—Fastening of Runners (A) to End Section (B).

It will be noticed that the end grain of the sides shows in front. If this is objected to, as it probably will be, it is only necessary to fasten on a simple moulding, mitred at the corners, and carried round the drawer front. This gives a handsome appearance to the whole, and the unusual construction of the drawers can only be detected by an examination of the sides when they are pulled out.

Such matters as locks, handles, and method of finishing the work, either by staining, painting, or any other means, may be safely left to the consideration of the maker. If he follows the suggestions given, he may rest assured that he will have a chest of drawers which, for appearance and solidity, will compare very favourably with those of ordinary construction, and not be any less useful.

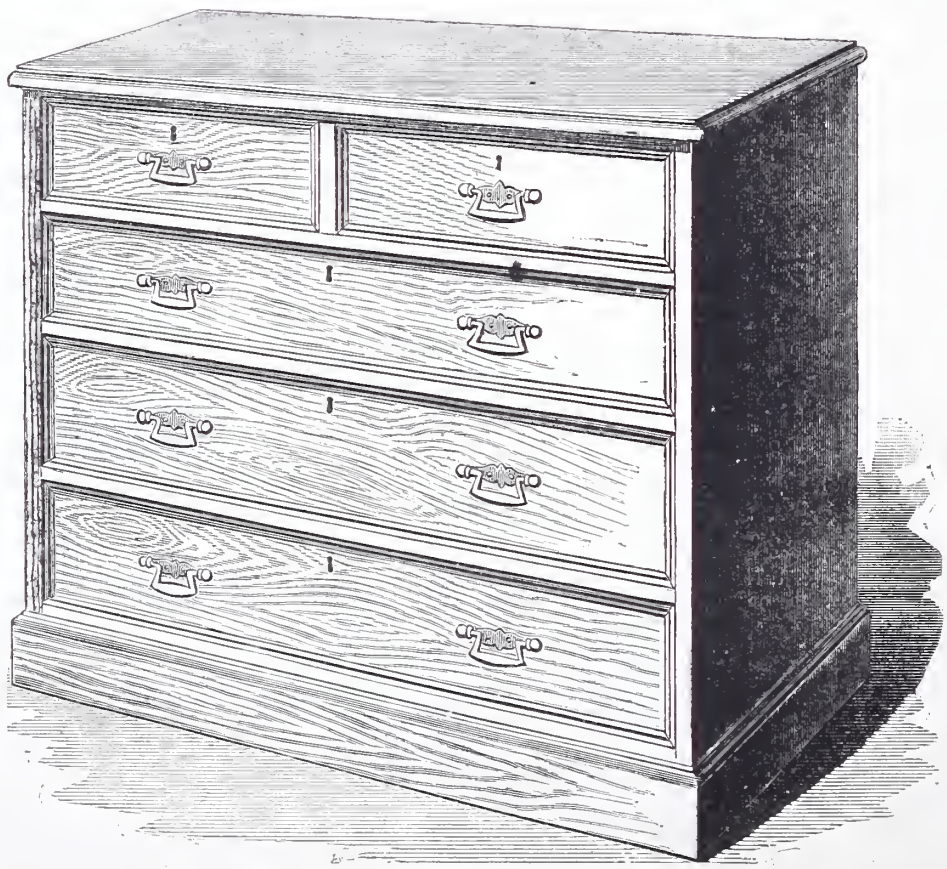

Fig. 1.—Easily-made Chest of Drawers: Perspective View.

## STAGE CARPENTRY.

BY WILLIAM CORBOULD.

ROLLERS: HOW TO MAKE, FIX, AND WORK THEM—THE FIXING OF THEIR ROPES, AND HOW THEY SHOULD WORK, ETC. ETC.

My intention in this paper is to explain, by diagrams, the way in which to make three or four different kinds of rollers or tumblers. A certain amount of skill is required in one or two of the rules, which I shall explain as simply as possible. The first will be a solid roller, which would do for a small cloth, such as 15 ft. by 12 ft. In choosing a piece of timber for this purpose, let it be dry, "straight," and clean, free from knots as possible, and about 3½ in. or 4 in. square. First plane off the four corners (see Fig. 1), which brings it to an "octagon," after which you go on planing off the eight corners until you get a nice round surface. Rub it over with a piece of coarse glass-paper, and you have a simple roller ready. You may now tack your cloth or scene on to it as it is, taking care that you tack it perfectly straight. It would be best to draw a line on the roller by the aid of your charcoal line, and tack to it: this will ensure the cloth rolling up straight. The way it should roll will be explained further on. Another good plan is to saw your roller straight through, placing the cloth between the two sections (see Fig. 2), tacking it on the face of one section. Afterwards place the two sections together, and put two, three, or more screws in them, taking care that the heads of the screws are level with the roller, or they will soon spoil the scene; countersink the wood a bit, so that the screw-heads are a little below the surface. Afterwards fill them with a little hard stopping of glue and whiting, with a

little boiled oil. When dry, paper off smoothly. This is a solid roller.

We now come to rollers that are what I will call "built." It is obvious that solid rollers, larger than the first one I have made, would be too heavy. When a roller reaches the dimensions of more than 3 in. or 4 in. in diameter, and, say, 15 ft. or 18 ft. long, it should be made hollow. There are several ways of making these. I will describe the two simplest. Suppose we are making a roller 6 in. in diameter, or thereabouts. First have a piece of timber about 5 in. square and 4 ft. or 5 ft. long; plane off the four corners, bringing it to an "octagon," the same as Fig. 1. You now saw this into pieces about 6 in. long. These are the cores which you build your roller on. You have now sixteen slating battens; bevel off two edges with the plane, making them somewhat wedge-shaped (see Fig. 3). When you have finished all of them, cut four in half, which gives you eight 6 ft. and eight 12 ft. lengths. Take first a 12 ft. length; divide this equally with five of your cores (see Fig. 4), taking care to have the one at the end (A, Fig. 4) divided in half, so that the next length will rest on the other half to butt or slope against the 12 ft. length (see B). This would be a 6 ft. length. Put a brush of glue between your cores and the battens; nail them down with 1½ in. nails. If you now go on alternately altering the lengths by placing a 12 ft. length alongside the 6 ft., and a 6 ft. by the side of your 12 ft., each time you will see that you break the joint (see Fig. 5). When you have got all your lengths together, you will find that the roller will be an 18 ft. one. You might extend it to 20 ft. or 22 ft., but it would not be advisable to go beyond that. Get it now on your bench or two tables, solid. As you have to plane off your eight corners to get it as round as possible, always remember, when nailing, to have your nails in the centre of your battens, or you will not be able to plane it round, let alone spoiling the plane. When you have worked it round and "smoothly" as you can get it, make some strips of canvas, about 2 in. wide and 6 ft. long. Commence at one end of your roller by first well gluing it all round for about 18 in.; take a strip of canvas, hold it slanting ways, and roll it round, just allowing the canvas to touch the edge of each turn. When you have got as far as you have glued, go on the same as before; and when you have finished, well rub down with a wet rag, the same way as explained in the making of "Profile" (see No. 140, Vol. III.).

Now for roller No. 3. This may be made to any size or length. Columns are made in the same way for large buildings on the stage, either interior or exterior, which must be light in structure, one man often having to carry one on and off the stage, where the scene has to be shifted quickly. The first thing is to prepare the cores, the diameter varying according to the size of your tumbler or roller. They are made of elm or beech.

*The way to get Roller out.* — You must not have the piece of wood less than 1 in. thick. We will suppose the roller to be 9 in. in diameter. Square out a piece of 9½ in. with your compasses, strike a circle 9 in. in diameter, and saw this all round: this is the solid disc or core. Should the laths or battens you are using to make the skeleton of (see Fig. 6) be 1 in. square, strike another circle on the core, 1 in. from the edge (see Fig. 7). Now divide the core into as many parts as you intend the skeleton should be made—that is, as many battens as you intend should form the circle to carry the outer skin or covering of profile. Now at the corner of each square, bore a hole either with gimlet or centre-piece, large enough to receive your profile saw (see Fig. 7). Cut out all the squares. These square-cut holes, as you no doubt see by this time, are to receive the inch square battens (see dotted lines, Fig. 6). You will want a core about every two or three feet, according to the size of the roller you are making. When you have ascertained that, and made them all, you commence putting your roller together. You must divide your battens, as explained in Fig. 5, in the making of roller No. 2; and where they join, dovetail them together (bevel on B, Fig. 4).

Fig. 8 represents the core when cut and finished. The square hole in the centre is for the purpose of a batten passing through the whole of the cores. In fitting the battens into the cores, use your glue brush, putting a fine inch and a half nail through the battens to the core (A, Fig. 6). We will now suppose the skeleton complete, and ready for the outer covering of profile. The profile

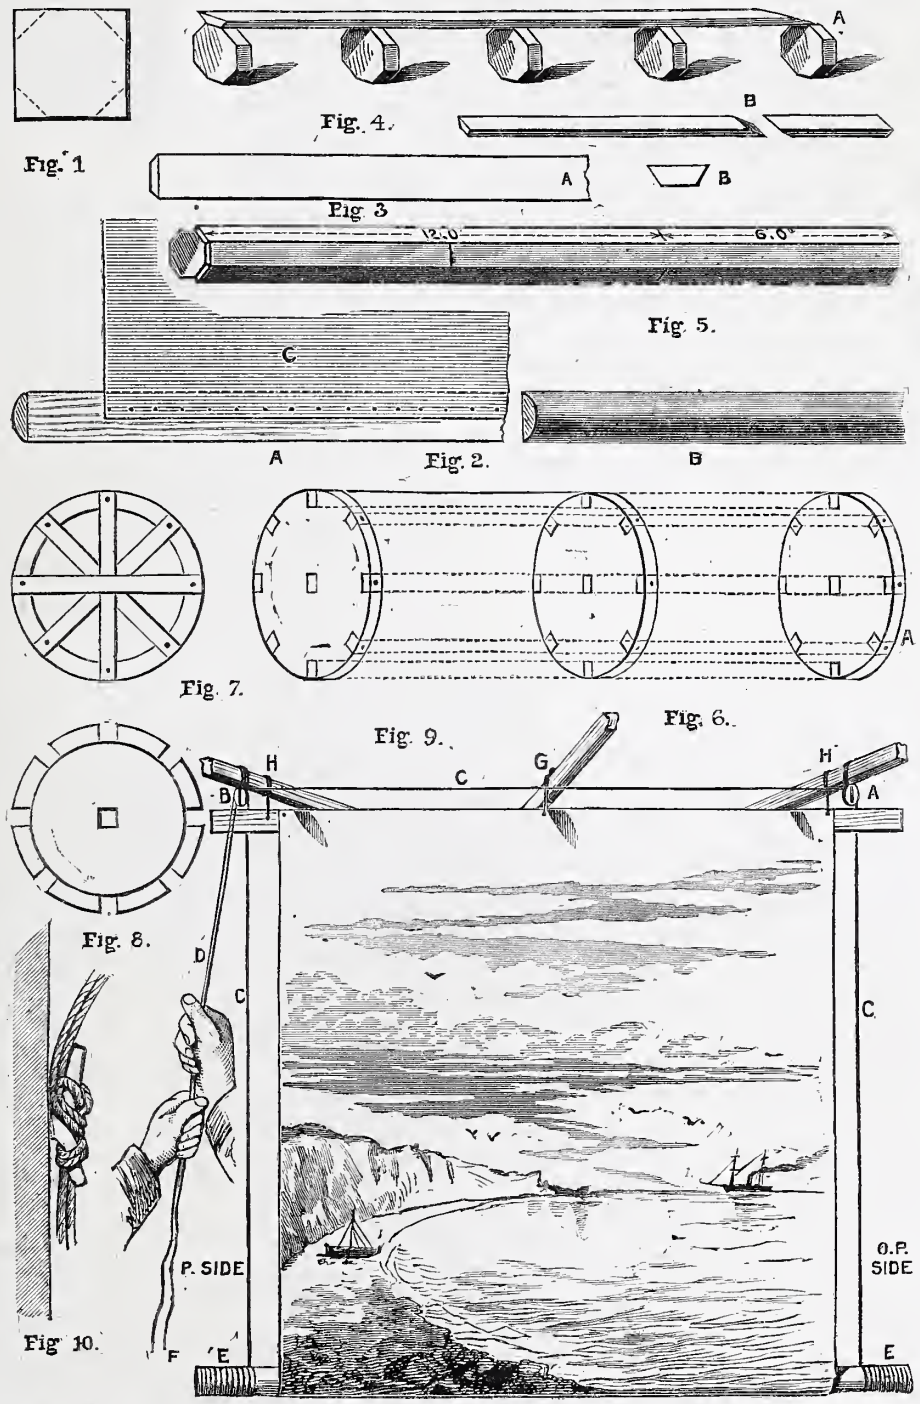

**Fig. 1.—Mode of shaping Octagonal Block. Fig. 2.—Rounded Roller cut in two, with Cloth (C) tacked on Part A before replacing Part B. Fig. 3.—Lath with Edges bevelled to fit on Side of Octagonal Block. Fig. 4.—Lath with End bevelled at A for Overlap by next Lath, as at B, nailed along Series of Octagonal Blocks. Fig. 5.—Laths tacked to Blocks so as to break Joints. Fig. 6.—Skeleton View of Large Circular Roller. Fig. 7.—End, etc., formed by nailing Laths to Ring. Fig. 8.—Disc notched to receive Laths. Fig. 9.—Method of Roping a Roller. Fig. 10.—Cleat for securing Rope.**

boards are laid on, and bent round to the skeleton. To do this, you must lay the board flat on your bench, and make a chalk line, about 2 in. apart—that is, divide the board its whole length, commencing 2 in. from either side. A 9 in. board might have four lines. Take your tenon saw and cut about half through the board, covering the whole of the lines. You will see now that you can bend the boards round easy enough. Have a good straight-edge to your boards, so that they may butt well together. Mark your first board where the cores are, so that you may know well where to nail to in the finishing. Should the profile boards be stout, you must have more cuts in them, or the roller would not be round. You may cover the joins of the profile with a strip of canvas, well rubbed down.

*How to Rove a Roller.*—To the amateur this is a difficult thing to do. We will suppose you were about fixing a cloth 18 ft. wide and 20 ft. high to the rafters. Forty-eight yards of rope would be required, one double and one single block. Fig. 9, A, is the single block; B the double block; C, C, C are the ropes attached to the roller running through the blocks to the hands at D, which part we call the fall, because as you haul the scene or cloth up, the ropes pass through the hands and it falls to the ground. When the cloth is right up, the ropes are fastened off on a belaying-pin or cleat (see Fig. 10), fixed to any convenient spot opposite the cloth, and clear of the head. It is usual to have them arranged in a row, where two or more cloths are hung together. The rope is attached to the roller either by a staple driven in the end of the roller at E E, the rope being passed through, and a firm knot tied in the end to prevent its slipping through, or the ends are nailed with clout nails, about 1 in. When the rope is fixed, it must be passed round the front of the roller, so that the part C is always at the back. We have the rope forty-eight yards long. First fasten at E, O.P. side; pass the other end through the single block, A, taking it through the back sheaf of the double block, B; then pass the end through the front sheaf of block B, and fasten it on the roller, E, P. side. Put about fourteen turns round the roller at each end, pull up, and when it goes all right, having two turns on the roller when it is up, roll up and down two or three times. To make sure, you may cut the rope at F, which will keep the coiling out of the ropes, allowing it to work right. G is the centre deadline, helping to keep the cloth straight, and free from bagginess. H, H are the two side deadlines. By the term "deadlines" is meant all lines that are fixed and do not work.

To the reader who may not know, I will explain what a profile saw is. You purchase the handle, which has two screws in it to hold the saw, and insert a saw blade at pleasure. The saws are very narrow, after the style of a keyhole saw, or compass saw, and cost about 3d. each. Of course, the handle will last for years; it costs about 2s.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### Work Involving Curved Lines.

Hitherto we have considered work with straight lines only, except the stuck or added decoration of mouldings.

We will now try to combine curved lines with the straight ones. The simplest form of curved surfaces presents itself in those cases where the larger surfaces are flat, but the edges are cut in various curved lines. Many examples can be seen in legs of forms and stools, wrought barge-boards, finials, ornaments for staircases, pierced and shaped balusters, canopy boards, the shaped legs of console tables, etc.

However these are cut when large numbers are required, the amateur will cut those he wants with either the bow saw or a compass saw. Now, the use of the bow saw depends on one very simple condition, which, however, is not easy to obey. The saw should be held so that its blade is at right angles to the board being cut. It is difficult to explain how this can be done, but consideration will prove that it is, and must be, the condition of accurate sawing. It may be needful to use the saw somewhat higher than is usual in wood fixed in the bench-screw, but some little practice will soon show the way, if the practice is combined with an effort to do the best, and a knowledge of the conditions to be observed. Sometimes it is difficult to see the line, because the saw is in the line of vision. In that case, shift the position of the wood. The cleaning-off of these curved edges will be done with a spokeshave, which should be kept sharp, and used with a constant reference to the most favourable way of the grain. Whenever any roughness or tearing results from the use of the spokeshave, reverse the action, and better work may be expected. For large curves, a compass-plane may be procured, but amateurs will not generally need it. Other curved work likely to be required by an amateur include shaped mouldings for the ornamenting of cabinets. In such cases it will be best to cut out the outline as above, making the joints either in a vertical or a horizontal plane, as may be required, and, by the aid of a template, cut to the profile of the moulding; carve it with chisels and gouges, using the chisels first to obtain the members which chisels can form; then those that need a gouge—hollow curves; then chisels to melt the hollows, where needed, into rounds; finally using scrapers made to suit the whole or part of the moulding, according to the size required. Many curved forms are made of thin wood bent round a strong-shaped mould. These offer a difficulty that is more one of method than of workmanship. Curved work is sometimes—indeed, I may say frequently—built up of pieces of segmental form, but this chiefly occurs in pattern-making, which is rather out of the amateur's province.

Thus in making a semi-circular heading, say to a wooden garden arch, or the arched entrance to a trellised porch, the amateur will find it convenient possibly to form it out of three thicknesses of wood, put together as segments of circles instead of sawing it out of the solid.

Mouldings can often be bent round curved edges, sometimes without, but often with the aid of sawing. This sawing is needful only when the curve is of small radius, or the moulding is thick. Instances can often be seen in staircases, on the edge of the skirting next the wall, and particularly in the case of winding stairs. When these saw-kerfs are necessary, glue should also be used, as well as fine nails or brads.

I do not think I have said that the spokeshave must be sharpened entirely on the inner edge, which is inconvenient but obligatory—inconvenient because of the two tangs which hold the blade in the handle; obligatory because the flat outer side of the blade forms the guiding surface of the tool, and therefore should not have its accuracy diminished by the use of the oilstone.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 115.—Manual Instruction in Wood.

The work before me purports to be "A First Year's Course of Manual Instruction in Wood," arranged for the use of teachers and pupils of elementary schools, by Joseph H. Judd, Member of the Institution of Mechanical Engineers (M.Inst.M.E.), and Head Master of the Brighton Technical and Manual Instruction School. It is illustrated with numerous engravings of tools and technical procedure in wood-working, and contains a useful appendix in the form of "Lecture Notes on Soft Woods in Common Use."

A glance through this pamphlet, which, I think, would have been better and more comfortable to handle had it been produced in ordinary book form and not in the shape of a small, oblong drawing-book, is certainly all that its author claims for it, and may be regarded as carrying out the principle embodied in it, and its general aim and scope—namely, that of a first year's course in wood-working—in a most satisfactory and efficient manner, and is none too much for any conscientious and intelligent student to accomplish in the first twelve months of his training, provided that he has the will and time to obtain sufficient practice in each lesson before he proceeds to that which immediately succeeds it. The exercises, so called, are twenty-four in number, and the first deals with the use of the two-foot rule for drawing and marking off material. The exercises, it should be said, are mostly in three parts—namely, (1) Introduction; (2) Description of Tools; and (3) Instructions. Exercises 2 to 6 inclusive are devoted to "sawing to a line" (along the grain), and the use of various tools that are chiefly used by the beginner, thus making him acquainted with the nature and uses of the tools he has to deal with, and what is to be done by their aid. The remainder of the exercises, from No. 7 to No. 24, is devoted to a consideration of the various modes of jointing, and includes many that may never have been heard of by some of our amateur wood-workers, and which have certainly not yet been touched on in the pages of WORK. For the benefit of my readers I will append a list of these exercises, so that if any of them are unknown to them, they may supply themselves with the book itself, which is published by the author at the Technical School, York Place, Brighton, and is sent by him post free to any address for 1s. To return to the joints described, they are: simple halving joint; dovetail halving (first method); half-lap joint; dovetail halving (second method); notching; cogging joint; bridle joint; stop bridle; oblique bridle; simple mortise and tenon; haunched mortise and tenon; oblique mortise and tenon; tuck tenon; bevel and mitre joints; and rebated and stop-chamfered frame with combination bridle and mitre joints. The method adopted in describing each mode of jointing is particularly good, and runs in this manner: Firstly, the application of the joint is shown, and the purposes for which it is adapted, and the uses to which it is put in practical work; then instructions for making the joint itself are given in due order, enumerating the various steps to be taken in due order from the beginning of the work to its finish. Thirdly, an equally useful step is taken in recapitulating these operations very briefly in due order of procedure, so as to give, as it were, a bird's-eye view of the whole in tabulated form; and lastly, a list is given of the various tools required and used in the construction of the joint under consideration. Mr. Judd's book is undoubtedly a good one. The Editor.

# SHOP:

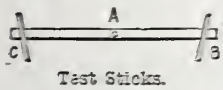
## A CORNER FOR THOSE WHO WANT TO TALK IT.

**** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given.*

### I.—LETTERS FROM CORRESPONDENTS.

**Short Lessons in Wood-working.**—J. C. K. (*London, N.W.*) writes:—"In column 2, line 15, p. 567, No. 140, Mr. Baxter says, 'See that these are parallel.' The pieces or their position when placed in relation to each other? 'These pieces are to be placed across the work, one at each end,' etc., as below probably. If placed by hazard a little oblique to right angles to piece A, the 'winding sticks,' C, B, may show truth, yet A may be 'winding.' How about the middle of A at o? this must be tested as well as the ends."—[The words "see that they are parallel" refers to the winding strips. If my polite critic reads the sentences before the words quoted, he will, I hope, understand. I may be allowed to humbly point out that the effort to plane two pieces so as to agree is advised, and precedes the mention of the winding sticks in my paper. J. C. K. may be informed that it is just possible that two surfaces agree, and yet neither be perfectly flat. The winding sticks are introduced as another step in the beginner's effort to attain the mastery of the plane. "The pieces are to be placed across the work at each end." J. C. K. may, if he chooses, use a try-square to test the exactitude of the position of the winding strips; then when he views them they will not appear foreshortened, and the test will be *slightly* more decisive, but the accidental deviation from a correct position will not matter to the young beginner. I take the word *across* to mean roughly at something near right angles, or to include such a meaning. J. C. K. ought to have read the whole of the short lesson, and he would have found—"When some facility has been obtained, the blade of a 12 in. square or a straight-edge should be employed to test the accuracy or the want of it." I think this is sufficient for a beginner, if not for a critic.—B. A. B.]



Test Sticks.

**Spots for Emigrants.**—DISGUSTED writes:—"For some time past I have been turning over in my mind whether I should not resort to emigration with the view to obtaining more regular work and better wages than are open to me in the old country. My chief difficulty is where to go to, and it has occurred to me that much service might be rendered to many similarly placed to myself were you to open your 'Shop' columns occasionally to a few suggestions from your readers who either are already or who have been abroad, and can speak with authority on the requirements for, and prospects of, the districts they know about. The labour market of England is overstocked, and I can do better out of it, if I can get my WORK."—[If you are disgusted with the old country, you ought to emigrate, but be sure and continue your allegiance to WORK wherever you are. We shall be very pleased to have the views of our home and many foreign readers about the best spots for emigrants.—ED.]

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Harmonium Reeds.**—GAMMA.—From what you tell us, there is nothing to be done but to put new reeds to the instrument. The old ones are evidently worn out, and do not offer that resistance to the air necessary to produce the sharp tone you require.—G.

**Ornamental Carved Stools.**—J. W. B. (*Huddersfield*).—Try an advertisement in WORK.

**Graining and Marbling.**—E. S. C. (*Gravesend*).—Your letter has been dealt with by our specialist. In case you have missed it, the name of W. Kirby, 46, Clipstone Street, Great Portland Street, London, is known to us as a good grainer and marbler. You had better question him yourself as to whether he teaches the art.

**Drinking Flask.**—J. J. (*Trealaw*).—We cannot give the maker of this a free advertisement in WORK by quoting his address. Any stamped letter shall be forwarded.

**Camphor Black.**—WORKITE.—Camphor black is not mentioned in the leading colourmen's lists in London. It was doubtless derived from a French or American list as a term to signify superior black pigment. To kill the yellow tinge in clay blue, not black, is used to be most effective.—J. C. K.

**Softening Dressed Rabbit Skins.**—ALLEN.—You can render them soft by rubbing. If, as you say, they are now so hard as to be liable to crack, you can make them more mellow by first rolling in a damp cloth. Draw them backwards and forwards over a blunt metal edge, such as a door scraper or through the handle of a drawer. The softening may be helped by working some mellowing substance into the skin, such as soft soap, grease, or oil. Kid skins are softened for glove making by saturating with yolk of egg, and then drawing them to and fro over a blunt knife. The skins brought from South Africa owe their exquisite softness entirely to patient rubbing between the hands of native women. You propose buying the back numbers of WORK. In them you will find information on this subject in various places, notably in Vol. II., pp. 294 and 330 (Nos. 70 and 104).—M. M.

**Pantograph.**—G. H. (*London, W.*).—A description of this appeared in WORK, No. 42.

**An Artist's Studio Easel.**—D. S. R. (*Cambuslang*).—This subject was treated in No. 142 of WORK.

**Window Frame.**—LEARNER.—Window-frame making has been treated in WORK, Nos. 125 and 129. Buy the numbers of your bookseller.

**Battery for Medical Coil.**—C. B. (*Old Street*).—The exciting paste in your dry battery was probably a paste of sulphate of mercury. If you clean the zinc and carbon rods and the cell, and recharge it with this paste on blotting-paper, the battery may be restored and put in working order. The Electric Stores Co., Cannon Street, E.C., have now some good things in the way of dry batteries, some of which are very small and powerful, and would, I think, just suit your small coil. I am glad to hear of your success with electric bells made from directions given in WORK, and also your achievement with a coil made from bits of information picked up in "Shop." You will be interested in knowing that something better in the way of coils is in the Editor's hands. The superiority of the pictures in WORK over those of some other journals is due to the fact that Messrs. Cassell & Co. have an art department, employing skilled artists and engravers, who work up authors' rough drawings into a presentable form before they are published in WORK. The journal you name merely transfers a copy of a rough sketch to a zinc plate, and prints a *facsimile* of a contributor's rough drawing, hence the scrawls of which you complain.—G. E. B.

**Electric Belts.**—C. V. (*Bristol*).—I think the flexible wire cords should be soldered to the insides of the zinc discs. If put on the outsides, they would, as you remark, be liable to chafe the skin, and this must be avoided by all means. It would be an advantage to have two or three rows of discs in the width of a belt, but the discs should be small to avoid overweight of the belt. The number of discs is immaterial—about a dozen in a row, divided into four sections of three in each section, would be enough. Connect them by flexible wire cord, not by wires only. A great interest is being taken in this subject just now, and several persons have written to tell of the benefit they have derived from wearing these belts.—G. E. B.

**Medical Battery.**—J. R. (*Glasgow*).—I suspect you mean a medical coil, although you have asked for a medical battery. Any galvanic battery will serve as a medical battery if you have cells enough in series to generate the necessary pressure or E.M.F. to send the current through a body. This may be done with a small medical coil and one cell of a battery, so I suspect you want a coil. I have not space at my command here to describe one, but there is a series of articles on the subject in the Editor's hands, and a full description of such a coil appears therein.—G. E. B.

**Electric Belt.**—N. S. (*Cambridge*).—So many different electric belts have been and are advertised that I am unable to say how the belt is made to which you refer, as you only give the price of the belt as a clue for my guidance. I have seen several methods of making these belts, and all agree in the material employed for the couples. These are discs, plates, or strips of zinc opposed to discs, plates, or strips of copper. Discs of metal from the size of a penny to that of a crown are generally employed in preference to plates or strips. In some belts the two discs are riveted together through the belt, with the zinc discs inside. In another form they are linked together by links passing through the belt. In another, the row of copper discs on the outside is made to overlap the edges of the zinc discs inside, and the two are connected by clasps on opposite edges. In some the rows run up and down across the width of the belt; in others the discs form parallel rows running the length of the belt; in others the rows are grouped as shown in your sketch. When grouped as shown in your sketch, the generated current will not pass around the body. The zinc discs must be inside next a flannel protection, and separated from the copper discs by thin flannel. The zinc of one couple must be connected to the copper of the next, and this is done by means of flexible wire cord soldered to the discs. There has been much about these belts in the third volume of WORK. Kindly get the index about to be published and search for yourself.—G. E. B.

**Coupling Transformers.**—NED.—As you have a spare transformer of the "same size and make" as that now in use, your course is quite clear. Couple the two transformers in parallel, and take current from both for your incandescent lamps. There need be no fear of burning anything up, as transformers of the "same size and make" are destined to run in parallel, and, therefore, do not differ in the direction of the winding. If you cannot determine how a transformer is wound by examining the wires and connections, you may do so by noting the direction of the induced current. If this differs from that of its companion, then it is probably wound in an opposite direction, always presuming that you connect both to the source of current by the right terminals. If you find the current from the second transformer going in the wrong direction, alter the connections and send the direct current from the dynamo in the opposite direction. But if you are going to supply current to a new set of lamps in another circuit, the direction of the induced current need not be taken into consideration, since incandescent lamps will burn equally well when the current is sent through them in either direction. There will be no difficulty whatever in connecting the voltmeter to them by means of branch circuits controlled by switches. Merely put in a looped circuit as for an extra lamp, and have a switch in the circuit in the ordinary way. The pressure will be the same in all branches of the same circuit.—G. E. B.

**Enamelling Electro-Plate.**—E. A. (*Sheffield*).—I think you must mean lacquering electro-plated articles, not enamelling, since the process of enamelling proper would injure the electro-plated surface. Electro-plated surfaces are protected from injury by giving them a coat of transparent lacquer. This may be tinted with aniline dye to any colour, and the coat will then resemble enamel. I have found the transparent lacquer named Kristaline, sold by Messrs. J. E. Hartley & Sons, a very good lacquer for the purpose. It may be applied with a soft varnish brush on the previously warmed electro-plated goods, or these may be dipped in the lacquer, then hung up in a dust-proof closet, heated to 90° Fahr., to drain and dry. Electro-plate thus protected is almost untarnishable and may be exposed to the fumes of gas or damp sea air without "going off colour."—G. E. B.

**Recharging Electric Bell Battery.**—OLD BOAT.—From your description of the battery I infer it to be a Leclanché battery. The inner cells are of porous earthenware, filled with a mixture of manganese and carbon peboles packed closely around a central plate of carbon. The glass cells are to be charged with a saturated solution of sal-ammoniac—that is, as much sal-ammoniac as will dissolve in enough rain-water to nearly fill the cells. This will take nearly ½ lb. of sal-ammoniac, and will cost about 6d. First fill up the jars with warm water, and add about a tablespoonful of spirits of salts to each. Allow the porous cells and zincs to soak in this for half an hour, then brush them with a hard brush, and rinse in clean warm water. Clean the screws with emery-cloth, and clean the ends of the wires from the zincs, so as to have clean wires clipped by clean screws. Connect the zinc in one cell to the screw of the carbon in the next cell, and connect the zinc of this cell to the bell wire. The other bell wire will go to the carbon in the other cell. Charge the cells to within 1 in. of their tops with the mixture of sal-ammoniac and water mentioned above. The stuff may be got from a druggist, or a drysalter, or an oil-and-colour shop.—G. E. B.

**Consumption of Steam.**—G. B. (*Armadale Station*).—We are unable to give our correspondent the information he seeks, inasmuch as he does not furnish us with the two most important points needed to enable us to ascertain the facts, and these are—first, how far the steam is allowed to follow the piston in the cylinder before it is shut off from the boiler—*i.e.*, what is technically termed the point of cut-off; and next the number of strokes per minute in the single-acting engine, and the number of revolutions per minute in the other, and whether there are one or two cylinders to this engine. When we have these particulars, we shall be happy to settle the question.—C. E.

**Compressed Air Engines.**—SIMPLE FIDELLS.—It is only for special purposes, where a very light motor is required, or work done in places difficult of access—as in mines and tunnels—that compressed air can be recommended for conveying power. The original power is supplied by an air compressor, and the air becomes heated when compressed; the heat thus generated, in part or entirely, passes away in waste by radiation. You can no doubt compress air by a windmill working air compressors, but it would be far more economical to store the power by pumping water into an accumulator and drive your lathe or other machine by an ordinary hydraulic engine. An air compressor for high pressure is not easy of construction except by a specialist. On this subject I think you might get information from Messrs. John Fowler & Co., Leeds. For particulars of hydraulic engines you might apply to Messrs. Tangye & Co., Birmingham.—F. C.

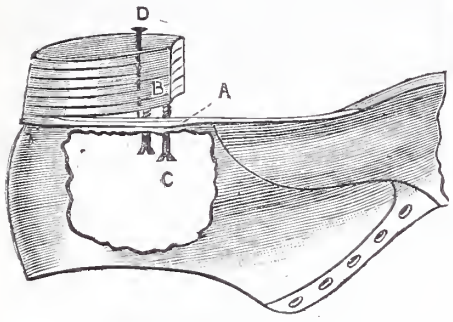
**Roller for Mangle.**—AMATEUR TURNER.—Any wood turner would supply you with this; or write to any maker of mangles—Kant & Co., High Holborn, London, or Harper Twelvetrees, Finsbury Square, London.

**Lathe Wheel.**—GAMMA.—Your best plan would be to sell the weights, and buy a metal wheel with the proceeds. I sometimes get cast-iron mowing-machine wheels for 1s. or 1s. 6d. If you had a small wooden cart-wheel, you could weight its rim by boring holes at intervals and pouring melted lead in. Whether you could beat the clock-weights into shape depends upon their present form, but probably not. It would be much easier to melt the lead and cast it in a mould.—SELF-HELPER.

**Hand Saw.**—DOBBS.—Your question in reference to grinding a hand saw at home rather surprises me, as the simplest form of grinding machine would

cost a deal more than a good hand saw; therefore it would not pay you to erect such a machine merely to grind one saw. It would be far better for you to purchase a saw of the thickness you require. A saw may be ground thinner by placing it between two grindstones, each stone revolved in an opposite direction, the stones being revolved by toothed wheels. But even such a simple device would cost you more than several new hand saws; and after the saw had been ground it would require glazing to give it a fine surface. This would add to the cost. My advice to you is to abandon the idea of grinding your hand saw thinner.—A. R.

**Repairing Heels.**—J. B. (*Dalton-in-Furness*).—By what I can glean from your question I see no reason why you should take the heel down and rebuild it. It is not quite your fault, for it should not have given way there unless you knocked it about without regarding it as a shoe. But the best thing to do now is to bore two holes, each large enough to admit of a screw passing through, as at A in the



Heel-Repairing Diagram.

figure, and then make two small holes at B, just as a lead for the screws, which can be about ¾ in. or 1 in. long. Now screw the two well into the heel from the inside, as at C; then put it on the iron foot, and drive a long French nail in from the top just behind the screws, as at D, and I think you will then find the heel as solid as it was at first. Perhaps you may, by putting in another screw, be able to dispense with the nail. If so, so much the better, as nothing can then be seen of the job from the outside.—W. G.

**Repairing Shoes.**—J. B. (*Dalton-in-Furness*).—You say you have soled a pair of shoes, and when you were taking off the old sole the under one came away. This being so, you should not have soled it until you had first repaired the damage you had done, which should have been rectified in the following manner:—If you are repairing on an iron last, or an iron-bottom last, hammer the middle sole (the under one) back into its place, first taking out all the old nails; then, supposing the line A A in the figure to be the place where the rivets will pass through the middle sole when you have put the sole on, put a few short rivets or long tingles, according to the sub-

Sole-Repairing Diagram.

stance of the bottom, in through the line B B. These dots show pretty well where the tingles should be put. They should only just be long enough to clench on the bottom of the last. If you are repairing on wooden lasts, when this is being done you must take them off and slip them on the iron foot to clench them, for they must be clenched before the new sole is put on. When you are putting the new sole on and patting in the rivets, put an extra long one in here and there, say an inch apart, and these just long enough to clench through the whole—that is, the new sole, middle sole, tops, inner sole, etc. The long rivets should be brass, so that when the shoe is soled again these will draw out with the thin old sole, and not disturb the middle sole again in so doing.—W. G.

**WORK in the Antipodes.**—REV. E. C. I. (*Kyneton, Australia*).—Glad to hear that WORK reaches you so promptly. As to your promising wood-carving pupil, Brocket, you cannot do better than write to Mr. G. A. Rogers, Wood-Carving School, Maddox Street, London, or Mr. Hemms (wood carver), of Exeter, England. We shall be very pleased to see the specimens of the work done at your school.—ED.

**Power of Model Engine, etc.**—A. H. (*Bridgeton*).—The power of your engine you can reckon yourself if you will read the explanation on p. 24 of the present volume. I cannot put it any plainer. The area of 1¼ in. is 1·2 sq. in., and the area of 1½ in. is 1·76. Say you have 50 lb. pressure in boiler and an average of 40 lb. per square inch on the piston:—Area of 1¼ piston=1·2 sq. in.; area of 1½ piston=1·767 sq. in.; 1·2 × 40 = 48 lb. on 1¼ piston; 1·767 × 40 = 70·68 lb. on 1½ piston. Now for speed, you can take 200 revolutions; piston moves 5 in. at each revolution, and 5 × 200 = 1,000 in. = 83 ft. per minute moved by piston; 83 × 48 lb. = 3,984 foot-lb.; 83 × 70 lb. = 5,810 foot-lb. Thus 1¼ diameter may give one-man power, and 1½ diameter half as much again.

**Hot-Air Engine.**—F. F. (*Homeland, Polk County, Florida, U.S.A.*).—Your letter has been forwarded.

**Barometer.**—W. B. R. (*Westbury*).—It is not possible, by the method you suggest, to construct a barometer using either glycerine or any other liquid except mercury. The diameter of the tube does not in any way enter into the question. The same height of column would be required whether the tube were $\frac{1}{100}$ in. or 100 ft. bore. As the specific gravity of pure glycerine is about 1·2, the length of the tube must be at least 30 ft. Of course this is out of the question for an amateur. In order to make a satisfactory mercury barometer, so many precautions have to be taken that I should advise W. B. R. to either refrain from attempting the manufacture of one or else to purchase one direct from the makers, who have every facility for the process.—J. G. L.

**Nozzle for Water Motor.**—R. R. T. (*Frome*).—If you have a supply pipe running full, there is no reason why you should not use a nozzle ¾ in. diameter. It would be an advantage to make the floats concave towards the jet, so that its pressure may be always normal. The running would certainly be improved by the introduction of a fly-wheel. You do not mention the length of pipe through which the water flows, so it is not easy to determine the power; but if you have a pressure of 150 feet, and only a short delivery pipe, the discharge through a ¾ in. adjutage will be about 90 gallons per minute: so the work done by the water would be 90 × 10 lbs. per gall. × 150 ft. fall = 135,000 foot-lbs. per minute. The form of motor used might give an efficiency of 33 per cent., or 45,000 foot-lbs. per minute. The corresponding horse-power is 45,000 ÷ 33,000 = 1·37 h.-p. nearly.—F. C.

**Wire Gongs.**—VERY ANXIOUS.—Of the making of these I have had no chance of observation or knowledge. Therefore, rather than lead you astray, I will ask those readers who possess the information to respond as promptly and generously as did those who replied to a query concerning mole-traps, which was as equally a puzzle to me. A set of deep-sounding chimes as fitted to American clocks is what particulars are desired of.—J. S.

**Venetian Iron-work.**—T. M. M. (*Bristol*).—As far as I know, W. Whiteley, Westbourne Grove, W., is the only firm which keeps in stock the iron strips used for Venetian iron-work. At the builders' counter in the ironmongery department of this business, you can obtain everything connected with this style of work. The strips are to be got ½ in., ⅝ in., and ¾ in. in width—any other width to order—and they are 18 in. or 24 in. in length. They are sold by weight, the price being 10d. per lb. The necessary tools can also be got there; those sufficient for beginners can be purchased for some few shillings. They consist of one pair of flat snips, one pair of 4½ in. flat-nose pliers, one pair of 5 in. flat-nose pliers, one pair of 4½ in. round-nose pliers, and one pair of 5 in. round-nose pliers. Iron wire for attaching is 8d. per lb. I feel quite sure that if you write to this firm, they will forward you all the materials necessary for your work. If you should, after all, prefer to buy the goods personally, I think you can order the strips from any ironmonger's, but it will always take some few days before you will get them. The strips are mainly cut from large sheets of iron in "24-wire gauge quality," as the technical term is: each sheet is 6 ft. by 2 ft., and the weight is about 12 lb. As you will see, there can be cut two gross of strips, ½ in. wide, 24 in. long, out of one sheet, the price thus being ½d. for each strip. The black used for iron-work is Berlin black; it is kept by all ironmongers; it is to be applied after the work is finished, usually in one, sometimes in two, coats.—J. N.

**Weather-Glass Tube.**—BAROMETER, YOUNG AMATEUR, and OTHERS.—The reason for using such a long tube is twofold. (1) If a short length of tube, say 3 ft., be used, there is always a liability of an overflow when the barometer is unusually low (*high*, of course, in the glycerine barometer). (2) I gave 4 ft. as the length of tube, as this is a usual size; and by using this size a little latitude in the size of the bottle is allowed. One correspondent states that he cannot get the glycerine to rise more than 12 in. In reply, I may say that if this happened with an instrument made according to my instructions, the reason will probably be found in one of two things: either the barometer (mercury) was unusually high—and hence the air in the bottle was unusually compressed—or, as I think more probable, some mistake has been made in the construction: possibly in the size of the bottle. In reply to those correspondents who ask where glass tubes may be purchased, I may say, as I have already said, of any scientific instrument dealer, or, in default of these, Reynolds & Branson, Commercial Street, Leeds, or Messrs. Philip Harris & Co., Bull Ring, Birmingham.—H. L.

**Incubator.**—F. H. (*Finchley*).—It is a matter of choice whether evaporating tray should be fixed to centre frames or not. It is not absolutely necessary, but if desired it can be so fixed by a couple of lugs or ears soldered to bottom of tray. As the lamp flue forms part of the evaporating tray, it must be fixed to it with hard solder, as stated in the article. The radiating disc need not be fixed. It is better if loose and laid between the arms of tripod, which should be shaped as Fig. 1 herewith, and which should grip the disc tightly. The lines in drawings on p. 609 are somewhat blurred and do not show this clearly. There is no sheet of metal over centre frames, as is clearly shown by reference to Fig. 3, p. 609. How is regulator to be fixed? This is a matter I quite overlooked. It should be fixed with a small metal strap, as shown by Fig. 2 herewith, the straight parts being slotted to slip over screws (round-headed) inserted in centre frames for the

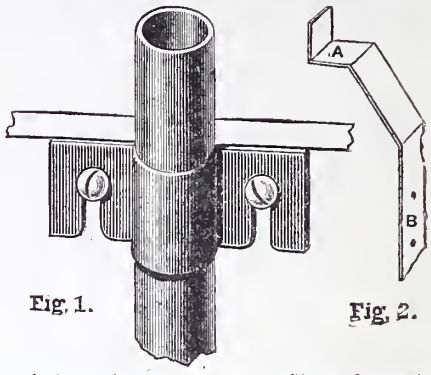


Fig. 1. Fig. 2.

**Incubator. Fig. 1.—Clip or Strap for fixing Regulator Tube. Fig. 2.—Arm of Tripod Head to Lamp Flue—A, Flat Portion for Disc to rest on; B, Rivet Holes.**

purpose. The hole in perforated zinc will fix the short limb. If the strap does not quite fit the long limb, a chip of wood pushed in behind the glass will make all secure. The float or plunger may be turned out of bone or ivory, or may be a cork nicely fitted, but if the latter is used, take care it does not get wet, or it will swell and bend in the tube. The former is the best, and it should be about ¾ in. long, and fit the tube without any play. P.S.—In reply to your second letter, please allow us breathing time. There is great pressure on "Shop," and each reply has to take its turn. Were it not so, it is a little unreasonable to expect an answer within a week, and in your case a diagram has to be drawn and engraved. Other correspondents please note.—LEGHORN.

**Microscopes.**—CANTAB has asked three very definite questions:—(1) "A short description how to mount object glass for microscope?" If you are purposing to use a good object-glass, I advise you to buy it mounted in its cell, and do not attempt to mount a good one yourself, as they are costly things. There will be a thread chased on the cell; a corresponding thread must be chased in the nose-piece. Supposing, however, you intend to experiment with a low-price lens, it might be worth your while to mount it. Fig. 1 is perhaps the simplest plan. A little cell is made to take the lens, which screws on to the nose-piece. Fig. 2 is a better plan, but more difficult, perhaps. (2) "The difference between the eye-pieces known as A, B, C?" The

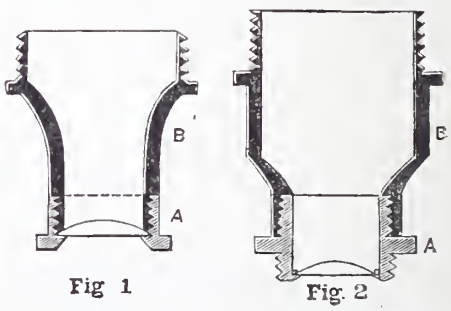

Fig 1 Fig. 2

**Microscopic Object-Glasses. Fig. 1.—A, Cell containing Lens; B, Nose-Piece screwed into Cell, retaining it in its place. Fig. 2.—A, Cell with the Lens bezelled; B, Projecting End of Cell carries a thread to carry a doublet or treblet.**

difference is simply one of magnifying power. There is no absolute measurement, as the power of an eye-piece all depends on the length of the power tube. The difference is only relatively. The optician who supplies you with the lens would, if desired, supply different powers. (3) "When may we expect the promised article on Eye-pieces?" In this matter I can only say the Editor is supreme, and he alone knows. Many others have asked the same question. I have no doubt at the proper time it will be forthcoming. I am pleased to know you are working from my design. I have heard from several correspondents who have done so, and it has gratified me to learn that they have succeeded, and are pleased with the results.—O. B.

**Amateur Mechanical Dentistry.**—S. E. (*Camberwell*).—First as to taking the impression and procuring model. To replace natural teeth that have been extracted with artificial teeth, supposing time has been allowed for the gums to heal, the mode of procedure would he thus:—Procure a variety of impression trays, also composition and pure beeswax, to be obtained at the dental depôts. Having found a tray to fit the mouth accurately, whether it be for upper or lower, you take a portion of composition or wax and soften it by placing in hot water. Be careful not to put any more composition in the tray than you want for your impression. When it has become sufficiently soft, take it and knead it well in the palm of the hand, after which, while it is soft, you shape it to fit the tray; and having placed it round the tray, you convey to the mouth of patient. If for the upper, you press well up, for the lower well down, taking great care that your tray is quite square and level in the mouth. Hold it in this position till the composition has become hard; then be very careful in withdrawing it, which must be done by raising the tray slightly by the handle, to allow air to find its way at the back of the palate, when it can he readily withdrawn. This requires great care, otherwise it will drag and give a false impression. In taking this impression it is necessary that it should be correct, for what your impression is so will your work be when finished. This accuracy can only be obtained hy constant practice. Supposing our impression to be correct, we then have to get a model from it. We take plaster of Paris, tho best to bo obtained at the dental depôts, and mix with water a little thicker than the consistency of cream, taking care to mix well to avoid air bubbles. We then pour into the impression sufficient to fill the tray. The remainder that is left in the vessel is mixed quickly with an addition of plaster, and is then placed on a flat surface to about the thickness of your tray; then take your tray and turn it over, so that the plaster may unite. When it has remained so for twenty minutes, you may trim round with a knife all superfluous plaster beyond the tray. When it has become quite hard, you may take it from the board, which it will readily leave by tapping the board, and place it in hot water. Let it remain until your composition has become quite soft, take it out, and the composition will leave the model readily; then you have a correct model, providing your impression is perfect. This procedure is precisely the same for plate work, only that your model must be made deeper. Supposing our model to be correct, and we have to make a partial upper case in vulcanite, we then have to obtain a correct bite. This may be done by taking impressions of both upper and lower jaws, and obtaining models from each. We now want to put, say, five teeth in the upper jaw. We now take some composition, made soft by placing it in hot water, and stretched to the thickness you will require your vulcanite to be, and pressed well into your model, exactly where you require the vulcanite. Then take toughened wax, made so by adding gum mastic, say two ounces and a-half to one pound of beeswax, with a little whiting added, melted together, and poured on a plate or other flat surface, previously made moist, or the wax will stick. When set, take pieces and warm them and fill in places on model where you intend the artificial teeth to he, taking care that the wax adheres firmly to composition already on model, having previously shaken a little French chalk all over the model to prevent the wax sticking. In some cases bonds or clasps are required, but we take it for granted that the present case is to be kept up by suction. Now take composition and wax combined off the model, and slightly warm wax only, either over spirit-lamp or by holding in a little hot water. You place it in the patient's mouth while wax is soft, and request the patient to bite up slowly; repeat this two or three times and carefully watch your patient's mouth and see that the lips meet with the case in the mouth without any effort whatever. Being satisfied that your bite is correct, you may then remove it carefully from the mouth, taking care not to break it, and place it on the model. Then you take your lower model and place it on the upper, when you will find that the indentations made in the wax while in the mouth will correspond with the teeth on model of lower jaw. Supposing the two models fit accurately one with the other, they are retained in that position hy placing an elastic band round them both to prevent them shifting. We then mix plaster of Paris rather thick and pour on a flat surface, to about three or four inches square and about one and a-half inches thick. Having previously painted the back ends of both models over with a non-adhesive liquid, obtained at the dental depôts, to prevent adhesion, place your two models in the plaster on the board (front of mouth upwards) and allow the plaster to set, when you will be able to take them up, and with a slight tap they will separate themselves from the back. You then take away your wax and composition and obtain your artificial teeth, having taken the exact shade of your patient's teeth, and grind them to fit the gum: lathe and wheels can be obtained at dental depôts. This, also, is one of the things that requires great care and practice. Suppose we are using pin teeth, you roughen the ends of both pins and turn them outward, thus, ⅂⅃. This must be done to prevent them dragging out when in use in the patient's mouth. You then take modelling wax sufficient to fill the place of the intended vulcanite. Having warmed it, you place it on the model and press well down, when it will remain in that position. Then take your teeth and place them in the vacant spaces, at the same time watching the length of your teeth for the bite, which is seen hy placing your two models together on the back. This also is very important. You then put more modelling wax round the backs of your teeth, sufficient to obscure the pins; you then trim and smooth off with modelling tools, for what your case is in the wax so it will he when finished. Your case is now ready for packing. More anon.—DENTA.

**Covered Strings for Piano.**—T. S. (*Bognor*)—I presume some of your strings are covered with white metal and the remainder with copper. I prefer copper-covered, as they retain their tone longer than the metal, so you may have them copper-covered throughout. I would advise you to send an inch or two of the first and last covered strings as to thickness, as well as the paper pattern, and write on the pattern fifteen single and fifteen double notes. The name of the ironmonger you require is J. and J. Goddard, ironmongers, Tottenham Court Road. You could get the strings made there if you choose. The price of covered strings fluctuates with the price of copper in the market. As a rule they are 2s. 6d. per lb. If you had described your instrument I could have told you the weight you would require. If it is a modern piano, about 4 ft. high, I should say 4½ lbs. would he heavy enough.—T. E.

**Wood Imitation.**—INQUIRER.—The only school that I am aware of, at which the imitation of woods and marbles is seriously taught, in London or its environment, is the establishment at Finshury in connection with the London City Guilds. Certainly there are a few private schools—or, rather, classes held hy leading marhlers, etc., for learners—but the fees are usually very high. I believe—and I speak from some knowledge and experience—that much more can be done hy home study and practice in these matters than hy class lessons and studies. To make the former thoroughly successful, however, these things are necessary: patient determination and continuous effort on the part of the student, and a good technical guide and samples by which to work. The former you must yourself supply, or "go under"; the latter you can get, in good value for the cost, from Vol. II. of WORK, or with every possible advantage that skill and coloured patterns can give by getting the "Art of Graining" from Manchester (see advertisement in WORK).—DECORATOR.

**Keeping Brushes Moist.**—S. J. G. (*London, W.C.*).—Paint hrushes naturally get hard and useless if left exposed to the air with paint in the bristles, since the very property that causes the paint to dry causes this hardening. If the hrushes are small and used very seldom, they should have the paint rinsed out with a little turpentino or petroleum, and then carefully washed *clean* with soap in warm water; well rinse in cold water, and then set aside to dry gradually. Don't use *soda:* it ruins the bristles; and don't use *hot* water—it dissolves the cement that holds the bristles to the handle. If the brushes are used too often for washing, the paint should be well scraped out, and then the brush stood in a vessel with sufficient water to cover the bristles, but not more than that, since the string binding the brush gets rotted. Varnish brushes you must serve exactly as those used for paint, so far as washing goes; but if they are large brushes, and required often, they must he carefully stood—not jammed—in a vessel containing raw linseed oil, instead of water as with paint hrushes. Scrape water, paint, and oil well out of the brush each time it is required and done with.—F. P.

**Bamboo Canes.**—G. R. E. (*Crigglestone*).—Bamhoo canes can be purchased in small quantities, of all sizes and dimensions, and at very reasonable rates, from Messrs. Eaton & Co., who advertise in WORK. Respecting a stain for bamboo to give a walnut colour, I think the best and easiest plan would be to purchase some good hard-drying (or "Church") oak varnish. This is a copal varnish, drying in about eight hours, and is then very hard for handling. Ordinary oak varnish does not dry sufficiently hard for articles of furniture, etc. Bamboo will not take a dye like ordinary wood; the former is not nearly so absorbent. I think, if you purchase a little—threepennyworth—of *best* burnt Turkey umber, ready ground in oil, and then mix this with the above varnish (say one pint), you will get a stain and varnish combined which will work easily, give any depth of colour according to the amount of umber used, and will dry hard and glossy.—F. P.

**Tarred Wall.**—RUFUS.—The proportion of hot Russian tallow to be incorporated with limewash as a coating for walls exposed to much bad weather is more a question of economy than ounces. Although 1 lb. of tallow to the gallon of wash would he sufficient for all ordinary purposes (this would be about 3 lb. to a good bucketful), double that quantity could doubtless be advantageously used in some instances; whilst 50 per cent. less than the proportion given would he sufficient to give a good, useful body to the wash. In every case the two ingredients must be thoroughly mixed and incorporated with each other before being spread.—F. P.

**Child's Cot.**—M. M. E. (*Openshaw*).—The only way in which I think you can overcome the nuisance occasioned hy the ends of the swinging cot wearing the supporting posts away, is, unless you face the damaged posts with iron, to curve each post on the side directly presented to the end of the cot, the curve embracing the whole area aggricved and extending as close under the bearing as is possible without weakening the post. The depth of each curve must, of course, be sufficient to permit the cot to swing without any part of it or its supporting irons contacting with the posts. If the damage results only in the immediate vicinity of the parts marked D in your sketch, then a short curve only will he necessary. A gradual curve is preferable to an ahrupt one, as with the latter the posts may be somewhat weakened.—J. S.

**Inlaying with Fret Machine.**—J. T. S. (*Sheffield*).—I must say that your present question is far from clear. What do you want to know? To say "inlaying with fret machine" gives no clue. If your wish is to cut inlay with a fret machine instead of with a "donkey" (the machine identified with inlay cutting), of course you can do so, although not so neatly or comfortably. The veneer should be placed between two thicker boards during the process. I cannot say whether any book on inlay shows a "donkey," or deals with machines, but if you would like a sketch of one I would prepare one for you in these pages similar to that I have seen a professional friend use with surprising ease and accuracy. The saw works horizontally, while the further end of the frame travels in a swinging pair of supporters.—J. S.

**Lenses: How to Grind them.**—J. A. (*Wandsworth*).—It is impossible to exactly say when the papers upon the above subject will make their appearance, but they will doubtless appear as soon as a favourable opportunity occurs. You should bear in mind that it is impossible to treat everything at once, and something must wait. In the meantime, if you have any special question, it shall receive every attention.—C. A. P.

**French Grey Paint.**—A READER.—The ingredients for making about 40 lh. of best glossy paint for indoors, tinted to a French grey colour, would be, say, ¼ cwt. (28 lb.) *genuine* white lead, 3 lb. best patent dryers, about ½ gallon raw linseed oil, and 1 quart turpentine. Break up the lead and dryers with a broad stick to the consistency of a thick paste, using linseed oil. If all is to be tinted one colour, for French grey add a little ultramarine blue (so-called) and either a little Venetian red or common hlack. If you want a "warm" grey, add the red; if a cool, metallic tint, add the black. The ultramarine you can only buy in powder; well mix this with a little oil before adding it to the paint; the other colours you will easily get ready ground in oil. Respecting the economical aspect of ready-mixed *v.* hest paint, it cannot be expected that the former, sold as low as 3½d. per lb. in some parts, can he equal in value to the best white lead paint, especially as you may have to give 4d. per lb. for the *genuine* white lead. The blue powder will probably cost about 2s. 6d. per lb., and you will require at least ½ lh. of that. The liquids lower the average cost. per lb. when the quantity is all made ready for use; but when you consider the time required for making the paint, matching a particular colour, and then straining the paint through muslin or a very fine sieve, the price usually asked for such best paint—viz., 6d. per lb.—is but fair value. Eight lb. of paint for painting the wall of one room is not at all a large quantity. For first coating on new plaster, you can use nearly all linseed oil and a little dryers—very little lead. This will stop the suction of the plaster, and then with two more good coats of paint you *may* make a decent job; but, as a rule, new plaster requires four coats to get a good surface. I am afraid you will find oil paint very costly for the house throughout. For the bed- and sitting-rooms I should strongly advise you to try "Alahastine."—DECORATOR.

**Fretwork Machine.**—TYRO.—Consult the indexes to Vols. I. and II., which can be had of any bookseller, at the price of 1d. each.

**Safety Fuse for Electric Lamps.**—H. M. T. (*Cornwall*).—You may include a 25-volt, 8 c.-p. lamp in a 50-volt electric lighting circuit if you place the lamp in a branch connected with the main circuit, and insert enough resistance in the branch to balance (together with the resistance of the 8 c.-p. lamp) the resistance of the 50-volt lamps. In doing this you will not reduce the voltage of the current (that is, current pressure), but you will reduce the volume of the current passing through that branch of the circuit. Ohm's law does not teach you that you can reduce the voltage in a circuit by inserting a resistance to the current in that circuit. It teaches you that the volume of current flowing in an electric circuit is equal to the total voltage, pressure, or E.M.F., divided by the total resistance of all the conductors in that circuit, according to the formula, $C=\frac{E}{R}$. We will apply this law to your case. The 25-volt 8 c.-p. lamp will take ·96 ampère of current to properly light it, or say nearly 1 ampère in a 25-volt circuit. We will suppose its resistance, therefore, to be 25 ohms. Now, if we placed this lamp in a 50-volt circuit, the result would be for a moment, $\frac{E\ 50}{R\ 25}=C\ 2$ ampères, the next moment darkness. Now, if we insert a resistance of 25 ohms in circuit with the lamp, the result will be $\frac{E\ 50}{R\ 25+25}=C\ 1$ ampère, the voltage of the current being the same in both, but the volume of the current reduced to one-half by the extra resistance. Include a safety fuse in this resistance to protect your lamp.—G. E. B.

**Dry Plates Backed.**—M. E. (*Leicester*).—Procure some hurnt sienna, ground in water, from the colour-dealer's, and mix it with equal parts of methylated spirit and water to the consistence of thick cream. The proportions are immaterial. Add a little caramel, say 2 oz. to ½ lb. of the sienna, and ½ oz. gum arabic,

dissolved in water. The whole being thoroughly mixed, a hog-hair brush, charged with the compound, is passed over the back of the plate, painting to within about half an inch of the edges, and then kept in the dark to dry. A very small quantity of the paint is sufficient. The plates can be backed in this manner and put in the dark slides whilst wet, but if any quantity have to be done it is best to let them thoroughly dry in a warm room. Set on a shelf, face to the wall, great care being taken to prevent light getting to them. Any plate-dealer will supply backed plates to order: they are not usually kept in stock.

### III.—Questions Submitted to Readers.

**** *The attention and co-operation of readers of* Work *are invited for this section of "Shop."*

**Rubbering Steel.**—A. H. (*Manningham*) will thank any reader to give him information regarding "the best method of covering a steel ring with indiarubber, *not* by vulcanising."

**Black Skin Dye.**—M. T. (*Newcastle*) writes:—"Will any reader kindly oblige with information as to what will dye a hare-skin black?"

**Paste Diamonds.**—J. H. (*Bury*) will thank any reader of Work to give him information how paste diamonds are made.

**Fender Designs.**—N. E. R. H. (*Newcastle-on-Tyne*) writes:—"Would any reader kindly tell me where I could get designs for a large fender top, say 9 in. high by 10 in. broad, and 3 ft. 15 in. long—or higher, if pillars are required? Is there anything new in patterns?"

**Screw Cutting.**—Lathe writes:—"I want to know of the best book on this subject. Replies will oblige."

**Sleigh Bells.**—A. S. (*London, E.C.*) writes:—"Can anyone tell me, through 'Shop' columns, how to alter the tone of 'sleigh' bells (metal) so as to match with others?"—[An important bell work the general method for tuning bells is by filing.—Ed.]

**Enamel.**—W. B. (*London, N.*) writes:—"I used some enamel on a brass ornament (which I previously cleaned), and applied it in a warm atmosphere, but the smell did not go off for quite three weeks, and fairly poisoned the atmosphere. Will any reader kindly say in 'Shop' what was the cause of this, and how to prevent it? I have a cruet-stand I want to apply it to, but fear the smell."

**Indiarubber.**—J. W. H. (*Brackley*) writes:—"Having a lot of old indiarubber I should like to utilise it. I should be glad if anyone could give me the current price for old indiarubber, and the best place or firm as a market."

**Marqueterie or Buhl Work.**—Subscriber A. W. writes:—"Can any of your readers give me information respecting marquetrie or buhl work?"

**Air Pump.**—H. S. M. (*Ripon*) will feel obliged to any reader who will give him information as to the Mawson & Swan air pump.

**Monuments and Tombstone Stains.**—Monumental Sculptor writes:—"I should feel greatly indebted, and I have no doubt many of my fellow-craftsmen would too, to be informed of some solution that will remove discolorations in marbles standing indoors and in the open air, and which solution would not destroy the marble."

**Electricity.**—P. L. (*Selly Oak*) writes:—"Will any reader tell me the price of a small, but good, book on electricity suitable for a beginner?"

**Softening Indiarubber and Metals.**—Ludovicus writes:—"What is used to make indiarubber soft enough to make rubber stamps? Also, which is the easiest way to soften iron or steel as soft as lead?"

**Monogram.**—B. R. (*Sandbach*) writes:—"May I ask if any reader of Work would kindly give me a monogram of the letters H. L. for painting on glass, to be seen through, and to be illuminated?"

**Oil Light.**—G. C. (*Pendleton*) writes:—"Will any reader of Work have the kindness to explain the mechanism of the Wells' oil light, or any other similar light produced from oil by the same means? Also if it could be advantageously used on a very small scale? The light alluded to is used largely among contractors and for out-door use."

**Pipe Mouthpiece Thread.**—S. M. A. D. A. (*Tunbridge Wells*) writes:—"Can any reader of 'Shop' oblige by informing me how to make the thread in amber mouthpieces for pipes? I can drill them, but not get a good thread for the screws."

**Engineering Examinations.**—Young Engineer writes:—"I would thank any reader to enlighten me as to any public competition or examinations in which an engineer student may compete, in order to lighten the cost to a poor student seeking to qualify as a C.E."

**Quarter Horse-power Gas Engine.**—T. P. B. (*Bradford*) writes: "Will any reader oblige by telling me how to make a ¼ horse-power gas engine, which would, I feel certain, be better adapted to all home workers than a steam one, as it would not require a boiler?"

**Lathe Outfit.**—Young Turner writes:—"I want to take up the lathe as a hobby, and should feel much obliged to any experienced turner if he would inform me the best kit to get, and where to purchase same. My age is nineteen."—[Young Turner should consult the advertising pages of Work.]

**Glass Cement.**—A.S. writes:—"I shall be obliged if anyone will kindly tell me of an adhesive for glass which will withstand continued wet."

**Banner and Flag Painting.**—Banner (*Wynberg, South Africa*) writes:—"Will any kind reader of Work let me know where I can get a book on flag and banner painting; also a firm for painter's materials; also books on coach painting, etc?"

**Bookcase.**—R. S. (*Chorley, Lancashire*) writes:—"Would any reader of Work kindly give me a sketch or some instructions of how to make a small portable bookcase, which would fold up and appear like a box, and not have too much work about it?"

**Microscopic Objective.**—W.S. (*Gosport*) writes:—"I have an objective mount of the usual English pattern, to which I want to put lenses for 2 in. focus. It is made for two lenses nearly together. I desire the shape of lenses, and the focal length of each, and whether one or both should be achromatic."

**Lenses.**—Scientific asks:—"Can any reader of Work tell me how to make and polish lenses, or where I can get the necessary information? Also, where could I get a good quality of glass for the above purpose?"

### IV.—Questions Answered by Correspondents.

**Wool Winder.**—M. (*Bishop Auckland*) writes, in reply to Mart (see p. 621, No. 143):—"Make a cross of two laths half lapped together, of a suitable size for the hanks of wool. Bore three or more ¼ in. holes in the ends, and fix four pegs in them 4 in. long. Make a stand of 1 in. board, 9 in. square; fix in the centre of this a piece of wood 1 in. high, with a

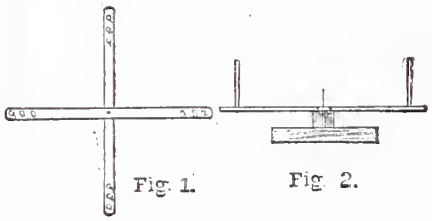

Fig. 1. Fig. 2.

Wool-Winder. Fig. 1.—Cross for holding Wool. Fig. 2.—Cross fixed on Stand.

wire in the centre. The stand should be weighted with a plate of lead, to prevent it being moved. The cross is fixed on the wire, and the wool on the pegs; as the wool is wound the cross turns round. Fig. 1 shows the cross; Fig. 2 the stand and cross fixed upon it. There is another form which folds up. If you want this, write again, and I will send sketch of it."

**Luminous Paint.**—F. S. (*Leek*) writes, in reply to R. R. (*Upholland*) (see p. 637, No. 141):—"The following is a good recipe: For orange luminous paint, 46 parts of varnish are mixed with 17·5 parts prepared barium sulphate, 1 part Indian yellow, 1·5 parts prepared madder lake, and 38 parts luminous calcium sulphide. For yellow luminous paint, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts barium chromate, and 34 parts luminous calcium sulphide. For green luminous paint, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts chromium oxide green, and 34 parts luminous calcium sulphide."

**Steel Springs.**—A. Darwin (*Harrison Street, Hillsborough, Sheffield*) writes to Wing (see p. 686, No. 147):—"Wing can be supplied with these by writing to the above address, coiled or in full length to coil himself."

**Modelling Wax.**—Eddifra writes, in answer to Carver (see p. 622, No. 143):—"Use white wax, melted and mixed with lard. In working it, the board or stone is best moistened with water, to prevent it sticking. Dip the tools also in water. To colour it, use dry colours."

### V.—Letters Received.

Questions have been received from the following correspondents, and answers only await space in Shop, upon which there is great pressure:—F. (*Huddersfield*); W. H. B. (*Salford*); A. C. (*Leeds*); D. C. (*Kinross*); Eddifra; W. G. W. (*Bruton*); W. A. Y. (*Poole*); N. W. (*Camberwell*); D. S. (*Stanley*); J. L. (*Harleston*); S. & J. (*Shanbryde*); Thornhill; A. B. (*Blackburn*); G. F. B. (*Victoria Barracks*); Amateur; D. L. (*Selly Oak*); W. E. N. (*Deptford*); E. D. (*London, S.E.*); J. B. (*Liverpool*); F. & C. (*Liverpool*); W. G. (*Ruabon*); J. S. (*Wakefield*); W. V. E. FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 155.] SATURDAY, MARCH 5, 1892. [PRICE ONE PENNY.

### A WORKMAN'S TOOL CHEST.

BY FRED CROCKER.

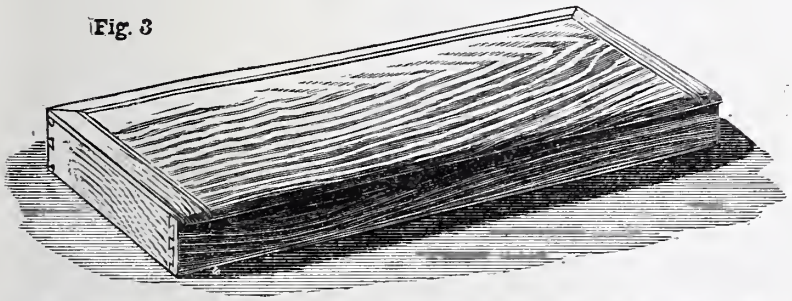
ADVANTAGES OF SLIDING TILLS—SIZE—MATERIALS—CONSTRUCTION.

IN making a "workman's tool chest," the object should be to economise space as much as possible, and to aim at lightness, combined with sufficient strength for the purpose required. The latter is necessary, especially for railway travelling, as they get rough handling by the Companies' servants, who—judging from the appearance of the tools after a journey—move the chest by tipping it end over end.

*Advantages of Sliding Tills.*—A reference to the drawings (Figs. 1, 2, 3) will show that sliding tills are given, which are preferable to the nest of drawers you sometimes find at the back of a tool chest. The former occupy less space, require less material and labour in making, and by sliding one over the other the whole length of each may be seen at a glance, and the tools easily found. Again, there is no danger of a tool such as a gauge binding against the bottom of the drawer above it; and there is also an advantage in packing: you simply tack a strip of wood in the slides at the ends of the tills to secure them, or use the space between as a clothes-box for working clothes.

*Size.*—The size, which may be gathered from Figs. 1 and 2, is smaller than that generally used by cabinet makers and joiners; but at the present time, when

Fig. 3



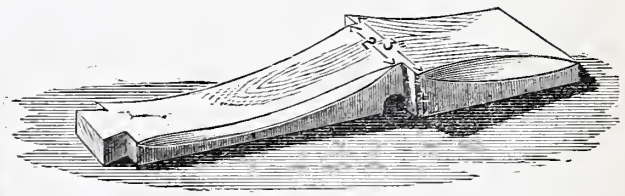


Fig. 4

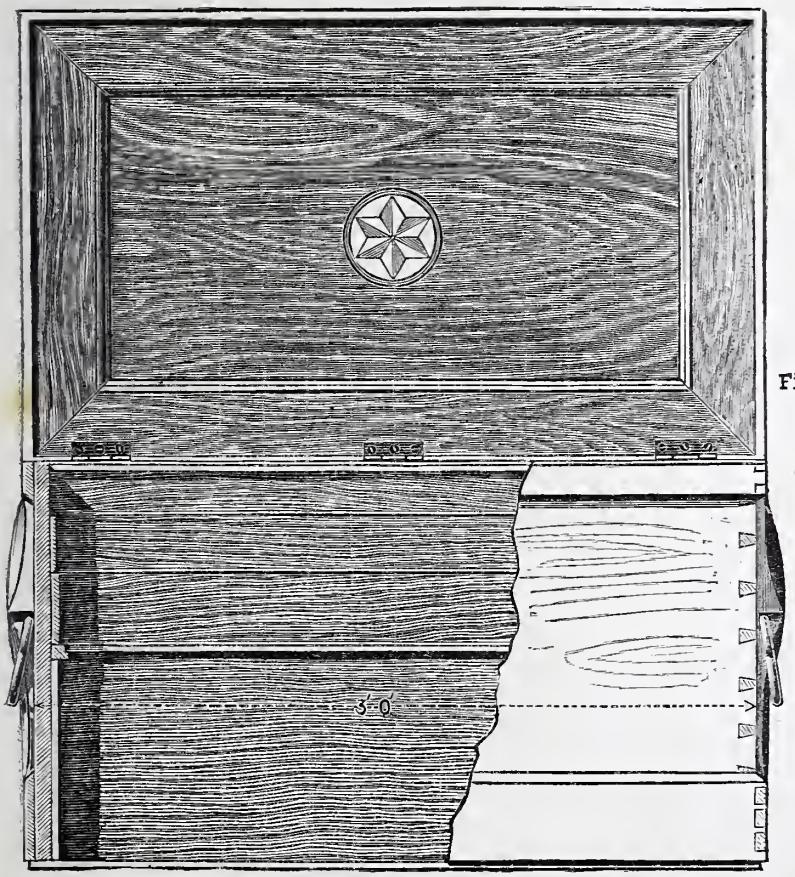

Fig. 1.

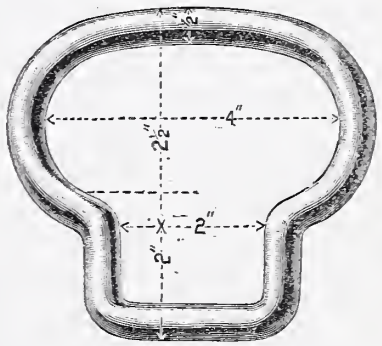

Fig. 5

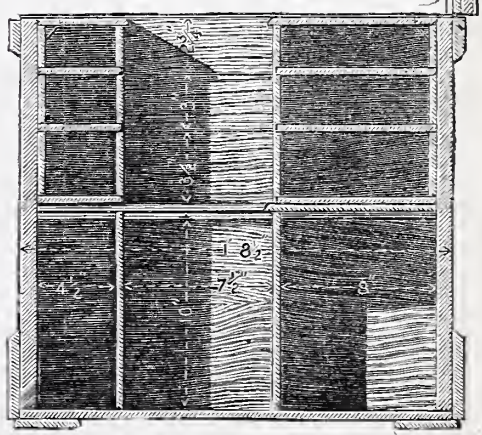

Fig. 2

Fig. 1.—Longitudinal Section and Part Front Elevation of Workman's Tool Chest. (Scale, 1½ in. to 1 ft.) Fig. 2.—Cross Section. (Scale, 1¼ in. to 1 ft.)
Fig. 3.—Top Till. Fig. 4.—Handle Bearer. Fig. 5.—Handle.

machinery is so much used, I should think it would be large enough for the average workman. This, however, may be modified to suit the particular trade or branch the maker may be engaged in.

*Materials.*—The sides and lid may be made of American pine, which should finish ¾ in. thick, and if not wide enough may be jointed; the bottom of ⅝ in. match-boarding; the plinth, etc., of Baltic deal; and the inside may be fitted up with Honduras mahogany ⅛ in. thick, which, for narrow boards, is fairly cheap, and is not so liable to twist as some of the more expensive qualities of fancy wood.

*Construction.*—First plane up and dovetail the carcase together, making the pins rather large; then screw the bottom on. Next the plinth may be screwed on sides and ends, and dovetailed at the corners—the pins being in opposition to those on the carcase, as shown in Fig. 1. Now the handles should be put on. These are made of ½ in. round iron (Fig. 5), and are far better than the pieces of rope you sometimes see used for the purpose. The handle bearers (Fig. 4) may be of oak, and should be screwed from the inside. A dovetail is shown at the bottom, which may be cut into the plinth if the worker thinks there is an advantage in using it. The handles should be kept well up, so that the chest will not turn over if it should at any time be craned. Next, the till slides are put on inside the ends. These consist of a piece of veneer for the top, a piece of ⅜ in. mahogany for the middle, and a piece of ⅝ in. for the bottom. To the latter is screwed a piece 1¼ in. by ¾ in., having a ⅜ in. rebate, to form a slide for the well board. Beneath this a block 7½ in. wide is fitted in, to which the well sides are secured. Some strips of mahogany ¾ in. wide by ¼ in. thick, and equal in length to the sides and ends, are now required. These are glued on round the top of the sides and ends, and mitred at the corners. The lid will be the next thing to occupy our attention. It is not advisable to clamp it, as the pieces at the ends are often a source of weakness. The inside is veneered, and banded with a 3 in. margin of ⅜ in. mahogany, mitred at the corners, forming a central sunk panel. The ⅝ in. ogee mould may be stuck on the edge of the margin, or may be planted in. The centre may be ornamented with a monogram, or some other simple inlay, as shown in the sketch. The plinth (½ in. thick) is next screwed on, and round the top some 1 in. by $\frac{3}{32}$ in. hoop iron (see Fig. 2). This protects the lid, should the lid be used as a sawing trestle at any time. Between the hoop iron the space is filled in with ⅜ in. board screwed on across the grain of the lid, and rounded at the edges. This protects and considerably strengthens it. Sometimes thick canvas is used instead of the ⅜ in. board. The tills are dovetailed together, the top ones (Fig. 3) having a lid. The margin, 1¼ in. wide, may be secured with angle blocks glued inside. The divisions lengthways may be made to suit the requirements of the worker; for instance, the top till (back) may have an 8 in. division at each end for bits, the centre being reserved for gouges or carving tools. Small knobs are sometimes put on the front of the tills, but these are in the way of packing; if anything is used for the purpose, it should be small flush rings. The bottom space at the back will accommodate such planes as beads, rounds, hollows, etc., placed on end; while that at the front may have a rack for saws.

The lid is hinged with three 2½ or 3 in. brass butt hinges, and a bead put on to line with the knuckles of the hinges, forming a sort of rule joint. This prevents the ingress of wet, dust, etc. A good lock should be provided, and two holes bored, so that the lid may be screwed down to prevent its being burst off. If the worker intends taking a trip to the Colonies, he may still further strengthen his tool chest by procuring a dozen pieces of thin iron, 6 in. long by 1½ in. wide, bending these to form angle plates, and screwing them on the outside. The inside should be French polished; the outside may have two coats of lead colour and one of brunswick black.

Minor details of construction are omitted, as they have often been given before; but should any difficulty arise, or should any practical reader have an improvement to suggest, the columns of "Shop" are always open.

## PRACTICAL PAPERS FOR SMITHS.

BY J. H.

ARRANGEMENTS SUITED TO VARIOUS TYPES OF SHOPS—STORAGE OF SMALL TOOLS IN RACKS—TOOL BENCH OR STAND—STAND FOR HEAVY APPLIANCES—MACHINES—VICES—DRILLING APPARATUS—SWAGE-BLOCK—STAND FOR SWAGE-BLOCK—HAMMERS—BOLT-FORGING MACHINE—SAWS—CRANE—STORAGE OF BARS AND RODS—STORAGE OF SCRAP—CONDITIONS AFFECTING THE FUTURE OF THE CRAFT.

IN this concluding paper I will treat, as I promised, of the arrangements of the smithy.

*Arrangements suited to Various Types of Shops.*—The arrangements of smithies, and their tools and appliances, differ as widely as do those of carpenters' shops or engineers' machine and fitting shops. From the country smithy of the roadside to the smithy of twenty or thirty fires is a long stage—a stage bridged by shops of all sizes and varied arrangements. In the small shops, machines and power-driving are *nil*; in the large ones, hand-work is reduced to a minimum. A few remarks relative to the arrangements of smithies of various sizes will, therefore, appropriately close this series.

My remarks will have reference to (1) small tools, (2) to machines and appliances, and (3) to storage of iron and scrap.

(1) *Storage of Small Tools in Racks.*—Small tools—as tongs, swages, fullers, flatters, punches, and such like—accumulate in large numbers, and litter the place unless proper means are taken to keep them in some order. There are two methods of storage—racks and stands. The most common method is that of racks, fixed against the wall by the side of the forge. These are simply stout parallel iron bars, supported between uprights, at a distance of from 6 in. to 8 in. from the wall, between which bars the shanks or handles of the tools, as the case may be, are dropped, their enlarged portions resting upon the top edges of the bars. The tool-racks against the wall are formed by driving two uprights into the ground at each end, and riveting the horizontal bars of iron to these. The uprights and the bars alike are of flat iron—measuring, say, 2 in. by ½ in.—placed edgewise. There may be two or three series of these horizontal bars, at heights of about a foot apart, dependent on the sizes of the tools used.

For the lightest tools, handled with withies, or with round rods, it is sufficient to employ short lengths of round rod riveted into flat bar. The flat bars are then secured to vertical uprights driven into the ground and leaning against the wall, and the rods stand out like spike nails. Upon these the light tools are hung by their handles.

The flat bars may measure 2 in. by ½ in., and the rods be of ½ in. iron, 5 in. or 6 in. long. These lighter racks should be placed above the racks of parallel bars just previously described.

A large quantity of tools can be easily stored in this fashion without occupying any of the floor-area of the shop, and are quite handy, since the smith has but to turn round from the anvil to pick out any tool required.

*Tool Bench or Stand.*—The other method is to have an oblong open bench or stand of wood, framed together with good rigid diagonals. The top is crossed with strips or rods, leaving open spaces, in which the shanks or the handles of the tools drop. Unless there is plenty of floor-room available, this is not so good as the rack, because the latter occupies scarcely any floor-space. But such a stand is very serviceable adjoining machines like the steam- or drop-hammer, or the Oliver. Without it, the tools would lie about round the machines in confusion.

*Stand for Heavy Appliances.*—For the heavier appliances used with the steam and other hammers, stands of a different kind are also made use of. Thus, two cast-iron standards of A form, with three or four pairs of internal flanges facing towards each other, carry stout deal planks between them, which are bolted to the flanges. Upon these deals the heavy spring-swages, die-blocks, cutting-off tools, hoop-tongs, etc., are laid side by side, the lighter on the top shelves, the heavier beneath, ready to hand, and without superposition of one tool on another.

(2) *Machines.*—The machines and larger appliances used in a smithy are very numerous in some shops, very sparse in others. In a country shop the vice, drill, and swage-block are frequently almost the only ones that merit notice; in large shops the steam or other hammer, the bolt-forging machine, the hot and cold iron saws, and the crane, are essential adjuncts. A few words on each of these must suffice.

*Vices.*—The ordinary tail or standing vice is, on the whole, as good as any. The high-class vices with parallel jaws and instantaneous grip arrangements used by fitters are scarcely suitable for the smithy, where the work is mostly of a rough character. If a regular bench is put up in the smithy, the tail-vice may be attached to it; or a small vice-bench, two or three feet in length only, may be attached to the wall beside the forge, and the vice fastened to that; or it may be self-contained, standing on a tripod anywhere in the shop, and so be movable.

*Drilling Apparatus.*—For drilling large holes, the ratchet-brace is the best tool to use. It can be fixed upon a bench in a permanent position, or it can be fixed where wanted on work in hand. A press-drill thrust down with a lever is also a common appliance in country shops. For a modern shop where drilling is done, a double-geared hand or power drill is the most efficient tool.

*Swage-Block.*—I have not yet alluded to the common swage-block, an appliance without which no smith's outfit is fairly complete. It is an almost universal tool. Its body is pierced with numerous holes—round, square, and oblong. Its edges are provided with indentations of curved and V'd forms, in various sizes. The block is used, when lying flat, as a bolster upon which holes are punched and drifted; and as a heading-tool, upon which shouldered work is finished. When laid upon one of its edges, the indentations upon the edges

fulfil the function of bottom swages for circular, hexagonal, and rectangular work.

*Stand for Swage-Block.*—The stand upon which the block is mounted consists of two cast-iron frames—an upper and a lower. The upper one is provided with strips, enclosing the block. The two are united rigidly by means of four shouldered wrought-iron pillars, whose pins pass through holes cast in the frames, and which are riveted over at top and bottom.

*Hammers.*—In a country shop destitute of power, the old Oliver is a most useful tool. It is efficient, easily and cheaply rigged up by smith and carpenter, and though, of course, not so rapid in its action as a steam-hammer, is its best substitute, and is entirely under the control of the forgeman. If power is available, then the drop-hammer is an improvement on the Oliver, and one that is employed in many large firms. With steam-power, the steam-hammer is the most efficient; but it consumes a large quantity of steam, requires the attendance of a man to operate the valves, and is costly, and therefore only suitable to large shops. Its place is always about the centre of the shop, to afford all the room available for the turning about and manipulation of long forgings, rods, and bars. Still, when the shop is of sufficient size to pay for the introduction of a steam-driven hammer, its uses are very varied and manifold; and fresh classes of manufacture can be developed that could not have been undertaken without the hammer. In a myriad ways the hammer can be utilised, and the slow operations of the striker be expedited manifold.

*Bolt-Forging Machine.*—The bolt-forging machine is a power-driven machine, by which bolts and their heads are formed between dies having a rapid vertical movement imparted from a long cam-shaft. Where bolts are made in even moderate quantities, the bolt-machine soon pays for itself.

*Saws.*—An almost necessary adjunct to this machine is the power-driven hot and cold iron saws. The first is a comparatively thin saw, run dry at a high rate of speed, that cuts through red-hot rods and bars almost instantly. The second is a thicker saw, that cuts slowly, running in water the while. The first makes a rough cut; the second is quite smooth and clean.

*Crane.*—The best crane for the smithy is a wall-crane that leaves the whole of the space underneath the jib quite clear. The framing is triangular, comprising the horizontal jib, the diagonal tie-rods above the jib, and the vertical rod upon which the whole swings. The top and bottom pivots of the vertical member turn in castings bolted through the wall. The jib is formed of flat parallel bars, upon which a light carriage or jenny runs, and from which the chain depends. The chain may be an endless chain with a loose sheave-pulley and hook, suitable for light weights; or differential pulley-blocks may be suspended from a hook for lifting heavy loads. The length of the jib will be such that it will command the forge-fire, the anvil, and, if necessary, any other appliances.

(3) *Storage of Bars and Rods.*—The stock of iron and steel bars and rods of a smithy should be kept in a shed, or at one side or end of the shop, stacked against a wall, the bars standing upon the ground and leaning against the wall. They can then be picked out without having to remove some bars to get at others, as must be the case when they are laid horizontally. As far as room will permit, all bars of different dimensions should be kept distinct. Short horizontal rods should be driven into the wall, standing out a foot or more, to divide the space into bays for iron of different sections and sizes—something similar to the arrangements used for stacking timber on end.

*Storage of Scrap.*—Odds and ends of iron bar and rod, and pieces cut off forgings, accumulate rapidly in a smithy. They are all valuable in turn, because they frequently save the cutting of a long bar. The best way to store these is at one end of the shop, spread over the ground; or, if space is limited, upon a stand like that used for the die-blocks and spring-swages. The less they are piled up the better, because, if spread thinly, any pieces required are more quickly seen, and selected for use.

*Conditions affecting the Future of the Craft.*—Owing to the gradual introduction of labour-saving machines into smiths' shops—the steam-hammers, bolt-machines, forging-machines, saws, etc.—and the increasing practice of stamping or die-forging, the craft of the smith is being affected in the same way that other crafts are being influenced. The inevitable result is sure to follow. Some considerable amount of skill will be sacrificed to specialty and to mechanical routine, and all-round smiths will become more and more scarce. But it cannot be helped. We are, all of us, the offspring of our age, and are borne along by its tendencies. All the more reason, however, why every craftsman should endeavour to gain a broad culture, and keep in touch with all modern improvements and studies bearing on his craft, and thus supplement the inevitable narrowing influences of the modern division of labour, and atrophy of manual skill and of the art of craftsmanship brought about by machinery.

## HOW TO CONVERT AN OLD HAND-BELL INTO AN ELECTRIC BELL.

BY G. E. BONNEY.

The Class of Bells which may be Converted—The Gong—The Magnet Core—The Armature—The Bobbin and Coil—The Contact Spring—Fitting the Parts—Battery to Ring the Bell.

Inquiries from correspondents respecting the internal fittings and mechanism of a Jensen electric bell have led me to think that there may be a few amateurs who are the happy possessors of old bell gongs which they may like to fit up as electric bells. The gongs referred to here, are those belonging to house-bells, worked with wires and cranks, or hand-bells of the church-bell pattern. These may be utilised as gongs for electric bells, and the fittings for the same may be enclosed inside the gongs, as in the bells introduced by Mr. Jensen. As there may be some readers of Work who would thus like to try their hands at converting a gong of the old system into an electric bell of the new system, I herewith give a few simple directions and diagrams to show how it may be done.

*The Gong.*—First a few words respecting the gong—that is, the bell itself—as we find it in the lumber room. It may be dirty and dusty, and attached to a rusty spring. We can do very well without all these accessories, so will clear them away at once. We will not bother ourselves about a handle to the bell until it is nearly finished. The bell may be of any size, from $1\frac{1}{2}$ in. across the mouth up to 6 in. I do not advise working on a larger or a smaller size than the above, as the smaller sizes will not afford much room to work in, and the larger sizes will take up too much battery power to work them. By this hint it will be understood that the fittings will have to be adapted to the size of the bell, and must be made proportionate throughout. I shall, therefore, not be able to give measurements of the various parts, as these must be found by measurements of the bells, but will give rules for obtaining these measurements, and also give the shapes of the various parts. The bell must be first cleaned, and the rusty spring taken off with an old rasp file; then a hole must be drilled exactly through the centre of the crown to receive the screwed shank of the magnet core and its insulating sleeve. The internal fittings of the bell will be held up by this shank, and it will also serve to convey the current to the magnet. It must therefore be strong, and must be insulated from the bell. A hole $\frac{3}{16}$ in. in diameter would be large enough to take the shank, but as this must be surrounded by an insulating sleeve of ebonite or boxwood, it will be advisable to take out enough to form a $\frac{3}{8}$ in. hole. This done, the bell will be ready for its fittings.

*The Magnet Core.*—In electric bells, there are usually two magnet cores, to hold two bobbins filled with wire. In this bell we have little space at our command, so shall have to put up with only one core and one bobbin of wire. As part of the core will pass through a hole in the crown of the bell, and be held in position by a nut on the top, we must take measurements for length of core from fully $\frac{5}{8}$ in. above the top of the gong down through the centre to within $\frac{1}{2}$ in. of the bottom. This will give the length; now for the diameter. This should be $\frac{1}{4}$ in. for a $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in. gong, $\frac{3}{8}$ in. for a 3 in. up to 4 in. gong, and $\frac{1}{2}$ in. for gongs above 4 in. up to 6 in. The material must be best soft iron. One end of this small bar must be turned down to form a shank, to pass through the hole made in the crown of the gong, and a screw-thread cut on its upper part (to fit the nuts, Figs. 8 and 9), as shown at Fig. 1. Just above the shoulder of this shank we shall want a thin collar or washer of ebonite or boxwood, to insulate the shoulder from the gong and to carry the contact spring, so must leave the shank long enough to take this, which must be thick enough to carry two short screws for holding up the contact spring. About $\frac{1}{4}$ in. below the shoulder, drill a small hole right through the core, to take a pin on which the gimbal or loose sleeve of the armature and hammer will hang. The lower part of the core should now be turned smoothly, and the upper pole-piece fitted to it. This pole-piece (shown at Fig. 2) is another piece of soft iron, from $\frac{3}{16}$ in. to $\frac{1}{4}$ in. in thickness, wide enough to allow a hole in one end to fit on the core, and long enough to allow the other end to project a little over the edge of the bobbin, as shown at Fig. 7.

A corresponding pole-piece will go on the end of the core, after the bobbin with its coil of wire has been fitted on the core, so should be got ready now. It must be understood that the very softest and best-annealed iron will be required in core and pole-pieces, to prevent the least trace of permanent magnetism being retained after the iron has been magnetised.

*The Armature.*—This also must be made out of soft, annealed iron, to the form shown at Fig. 3, then filed smooth and bright. The width of this piece should correspond nearly with the width of the pole-pieces, and its

thickness may also be the same, whilst it must be long enough to reach from gimbal to lower pole-piece, as shown at Fig. 7. At the upper end, it must be bent as shown in the figure, and this bent part filed down thin enough to go easily into the jaws of the gimbal, or loose collar holding the armature and hammer, as shown at A (Fig. 2). This part is best made of thin brass, which need not have a greater thickness than $\frac{1}{8}$ in., bent around the core to fit it closely on two sides of the oval. Its form is shown at B (Fig. 2). Its jaws will clasp the upper bent part of the armature, and be secured thereto by two small rivets, passing through holes drilled through the jaws and armature. At the opposite side of the oval, drill a $\frac{3}{16}$ in. hole, to take the end of the hammer-shank, which may be fitted in and soldered, or tapped and screwed in, as may be deemed best by the workman. The hammer-shank may be of iron or hard brass wire, from $\frac{1}{8}$ in. to $\frac{3}{16}$ in. in diameter, and long enough, when bent to shape, to reach from the gimbal down to the lower edge of the bell. The hammer-head is simply a small brass ball or marble, with a small hole drilled and tapped to receive the screwed end of the hammer-shank. The gimbal, with its hammer and armature, may now be set aside until the core has been fitted with its bobbin of wire.

*The Bobbin and Coil.*—The bobbin or reel on which the coil of wire is to be wound may be made of ebonite or of boxwood, or of *papier-mâché*. It must fit tightly on the core, and its diameter should be about three times the diameter of the core, whilst its length must be governed by the space between the pole-pieces between which it will be snugly clipped. The flanges may be $\frac{1}{16}$ in. to $\frac{1}{8}$ in. in thickness, according to size of bobbin, but the body should be turned down so as to leave just a thin shell between the core and the wire, because a better magnetic effect is produced in the core when the wire is brought close to it. Fill the bobbin with silk-covered copper wire, and see that it is free from kinks, knots, and bare places. The wire should be wound on evenly, as a reel of cotton is wound. Leave out about 4 in. of the commencing end to connect up the coil with; finish off at the same end of the bobbin, and leave about 4 in. of free wire for connections. The sizes of wire should be No. 28 for the small bells, No. 26 for the medium size, and No. 24 for the larger size bells. The bobbin may be wound on the core, or first wound and then slipped on carefully, to prevent fracture of the flanges. The lower pole-piece must then be fitted on with the same care. If the amateur is not able to fit these pole-pieces tight, they may be secured to the core by a small set screw in each piece. The relative positions of these parts are clearly shown in Fig. 7.

*The Contact Spring.*—This may be cut out of thin spring steel, spring brass, or German silver—the latter being preferable—to the form shown at Fig. 4. The broad part must have two holes drilled in it, as shown, to take two small screws for fixing it to the insulating sleeve (Fig. 5). At the other end solder on a thickening lug of brass to hold the adjusting screw, and drill a hole through lug and spring to take this screw. The small contact screw, shown close by, is made of brass. A tiny hole should be drilled in the end of this screw, and plugged with a tightly-fitting scrap of platinum wire, or a piece of platinum foil may be soldered over the end of the screw. The insulating collar (Fig. 6) should be of ebonite or of boxwood. This will occupy the position shown at A D (Fig. 7), and must be made to fit this part. It will there serve the purpose of holding up the contact spring, and insulating it from the gong and from the core.

*Fitting the Parts.*—The various parts being all made, we may now fit them together. First, plug the hole in the crown of the gong with the insulating sleeve (Fig. 5). Next place the gimbal in its position on the core, and secure it there by a pin of hard brass passing through gimbal and core. See that the gimbal swings freely on the pin, and is poised aright. The weight of the hammer should keep that side down close to the bobbin when the core is upright. When the armature is pressed against the pole-pieces, it should fit fairly and squarely on them. Now place the insulating collar (Fig. 6), with the contact spring fixed to it, in its proper position in the crown of the bell, and fit the core in its place, just to see how the parts suit each other. Curve the hammer shaft so as to cause the hammer to strike the edge of the bell. Curve the contact spring until it keeps the armature in its right position, close to, but not touching, the pole-pieces. Note where the contact screw touches the armature, and mark the spot. Take these parts out again, and solder a scrap of platinum foil on the back of the armature, on the spot where the contact spring touches it, then place the fittings back in their places. This time we may connect up the coil, and make all secure. Lay bare about $\frac{1}{2}$ in. of each end of the wire; secure one end under the contact spring as shown at D, and the other cleaned end against a cleaned spot on the gong under the insulating collar, as shown at A (Fig. 7).

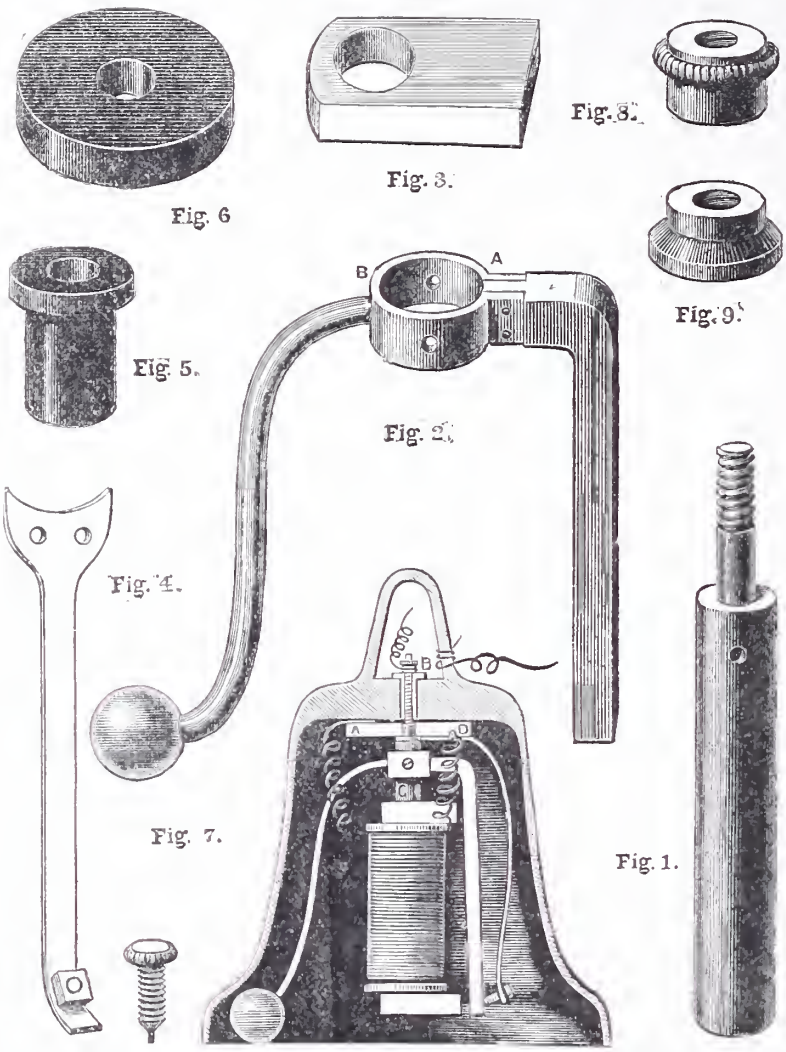

Fig. 1.—Core of Bell Magnet. Fig. 2.—Armature Hammer and Gimbal connected together. Fig. 3.—Pole-Piece of Armature. Fig. 4.—Contact Spring and Screw. Fig. 5.—Insulating Sleeve of Ebonite. Fig. 6.—Insulating Collar of Ebonite. Fig. 7.—Showing Internal Fittings and Connection. Fig. 8.—Upper Connecting Nut of Bell Magnet Core. Fig. 9.—Lower Holding Nut of ditto.

We may now see about a loop or handle for the bell. This is shown at Fig. 7 as part of the gong. A similar-shaped piece of brass or of copper may be soldered to our finished bell in the same position, or a piece of No. 8 brass or copper wire will serve the purpose for small bells. The handle will be hung on a bracket, and one of the line wires connected to the bracket, under one of its screws. The handle and the bracket will therefore form parts of the electric circuit; therefore, all points of contact must be clean. The other line wire will be connected to the binding screw on the bell, at the top of the magnet core. This wire should therefore be coiled in the form of a helix at the end, to ensure due flexibility.

*Battery to Ring the Bell.*—Two No. 2 Leclanché or Gassner, or E.S. dry cells will serve to ring the small bells, but three Gassner, or E.S. dry cells in series are recommended for the other sizes, as a battery of these cells furnishes a large volume of current for a long time without any attention.

## SCARF ORNAMENTS.

BY H. S. GOLDSMITH.

### Scarf Rings.

SPACE being in very great demand in this paper, short introductory remarks are advisable. They will be very few in this case, being merely the statement that this is written to explain the mechanical details of scarf rings—not the artistic. Thus, the same lines will be followed in this case as in the

previous papers in WORK on ear-rings and scarf pins.

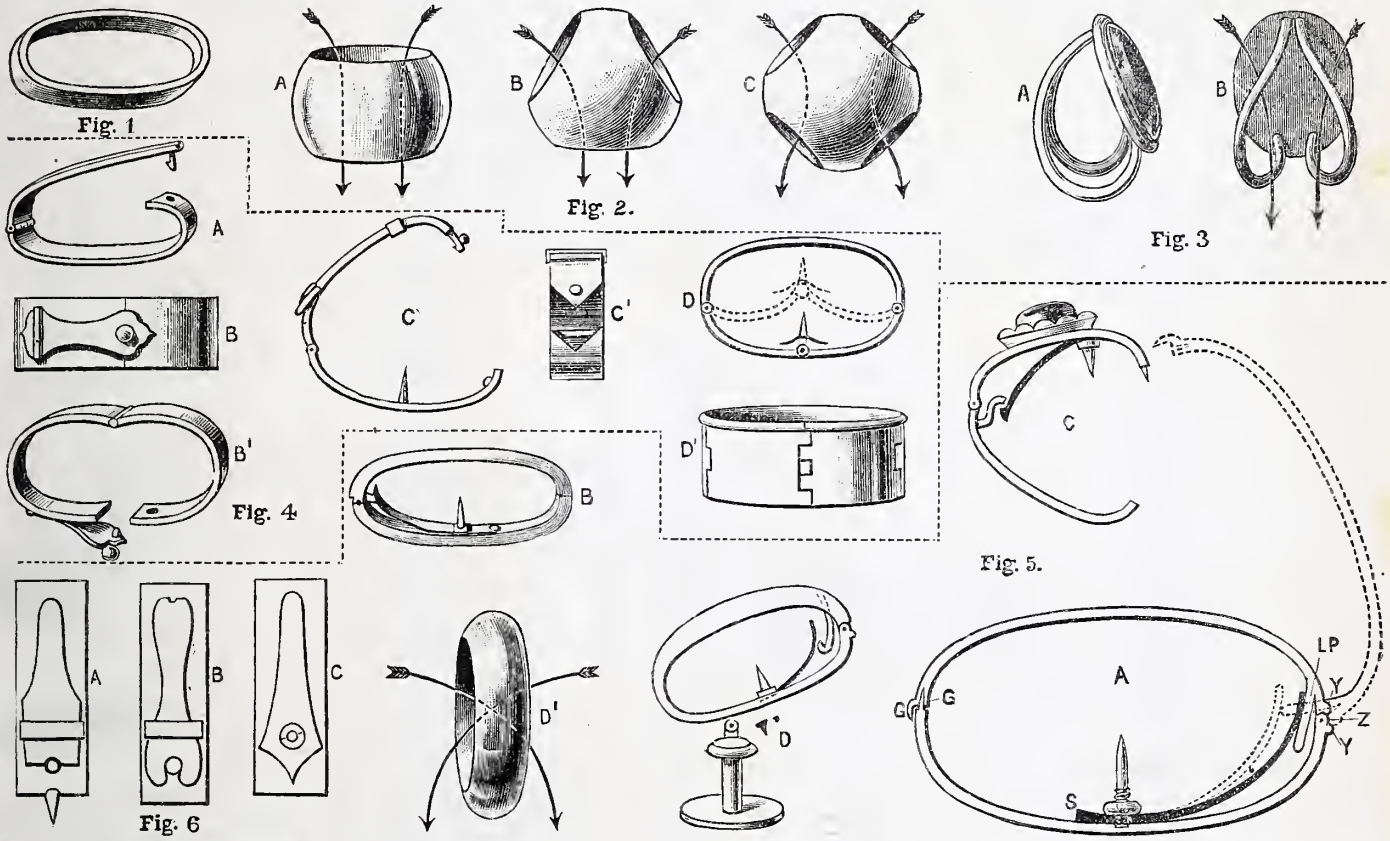
The simplest form of scarf slide or scarf ring is one that merely slides over the scarf, and is retained in its position by the two folds of the scarf, which, when passed through the same aperture, fit the ring or slide rather tight. Such a simple form of this ornament as these (which has nothing added to a plain oval or round mount to obtain security) can be put in the same class as finger rings, when they are used as scarf rings; and one feels rather inclined to believe that finger rings are the real originators of the article, notwithstanding the rather flat, oval form, now the most common shape in which this ornament is found.

that are generally made, and afterwards we can gradually note the complications as they are added. The simplest would be that shown in Fig. 1, which is an oval, plain gold band about 1 in. long and ½ in. wide, the depth being about ¼ in. to ⅜ in. These measurements are not to be taken altogether as standards, but as a fair average, they having been arrived at by comparison and measurement of several.

Three other very simple ones are shown in Fig. 2, A, B, C. They are all made from hollow, round beads, pierced by round holes in the various ways shown, the direction the scarf takes being indicated by the arrows. Of these, Fig 2, B, is the most usual, and can be just as well worn the other way up.

presently, there is a spike often added, which penetrates the scarf, to keep the scarf ring in its place; but with Fig. 3 there is no need of such a spike, because the wire mount is made to fit over the top part of the collar stud, and, generally, spikes cannot be used with any advantage unless there is a joint (as in Fig. 5, A, B, C, D) which allows the ring to reach its proper place on the scarf before it is closed, for it is by the action of closing the scarf ring that the spike is made to penetrate.

The first departure from the simple, rigid form is by making the band of two pieces and jointing them together, such as we see in Fig. 4, A, B, C, D. Three (Fig. 4, A, B, C) are held fastened by a peg on one piece,



**RIGID FORMS OF SCARF RINGS. Fig. 1.—Plain Band Scarf Slide. Fig. 2.—A, B, C, Three Simple Forms made from hollow Beads, pierced in different directions, the Arrows showing the direction the Scarf takes. Fig. 3.—Skeleton Scarf Slide Mount—A, Side View; B, Back View. JOINTED FORMS OF SCARF RINGS. Fig. 4.—A, Simple Form, fastening by a Peg snapping into a Hole; B, Another way of using the same Fastening, Front View; B', Side View of same, partly open; C, Fastens by snapping over a Bar; C', End View of same, partly open; D, Three-jointed Form, Side View, showing in Dotted Lines the Position when fastened; D', Back View of same, showing Construction of the Joints. JOINTED FORMS OF SCARF RINGS WITH SPRINGS AND LEVER PIECES. Fig. 5.—A, Enlarged Diagram; the two Halves are jointed at Z, two Stop-pieces to regulate the Opening, Y Y; L P is the Lever Peg attached firmly to one half; S, the Spring which acts against L P, Dotted Lines showing the relative Position when open; G, G, Guiding Pieces at the Shutting Edges; B, Form with Sunk Joint, and different Forms of Lever and Spring; C, Form with another kind of Spring and Shape of Lever Peg; D, One that is intended to be worn vertically instead of horizontally, shown in the Side View for another kind of Lever Peg, and the way it is attached to the Collar Stud; D', Front View of same, the Arrows showing the way the Scarf passes. Fig. 6.—A, B, C, Three Patterns of Springs.**

The finger rings most likely to be used for this purpose will be those with a very long oval head, composed of a border of stones surrounding a painting—*i.e.*, memorial rings, which, for the most part, were found to be rather uncomfortable things to wear on account of their size. Even now, it is not at all an uncommon thing to see a diamond ring or a signet ring worn on the scarf. However, it is not with these finger rings that we have to deal in this paper, but with the various forms of ornament especially designed for wear on the scarf—ornament where the scarf is retained in its place by being threaded through some ring-shape or other, instead of being skewered on, as is done with scarf pins.

Barring finger rings, we will, then, consider first the simplest forms of scarf slide

The next one (Fig. 3, A and B) is that wherein spaces or passages for the scarf are arranged by having a wire mount made and attached as shown in the sketches—one a side view and one a back view of the article. In this one the loops, in their upper part, are intended to fit over the front of the collar stud—hang on to it, as it were—and consequently to keep the ornament always well up to the top.

This skeleton pattern, as we may call it, seems the best to use when the front consists of a large oval stone—say, a cameo—for then the stone and its setting need only form the front; while, if a band like Fig. 1 is used for such a shaped stone, it will probably project on each side of the setting, and will not always look as if it belongs to the ornament, but more or less of a makeshift. As we shall see

snapping into a hole (Fig. 4, A and B), or over the bar on the other piece (Fig. 4, C). To either of these a spike, such as shown in Fig. 5, B, can be added.

The fourth (Fig. 4, D) has three hinges, and the position, when closed, is shown in dotted lines. The closed portion here is retained, because the front of the slide—which is somewhat of the shape of a bow—has the ends made to spring slightly inwards, and in that way it acts as a spring to force the inside plate and spike forward against the two parts of the scarf that are passed through it. The spike and plate is on a loose piece of joint, and forms the centre one of the five shown in Fig. 4, D'.

In three of these last, no reserve force is present to keep the ring closed, and once the scarf ring gets open, there is

nothing—except, perhaps, a spike—to prevent the scarf ring falling and getting lost. Such conditions not being satisfactory, the type illustrated in Fig. 5 is preferred; but both Figs. 4 and 5 are combined in one article sometimes.

For security, as well as for convenience in adjusting, we find that the greater number of scarf rings are now made like Fig. 5, A, B, C, and D.

These all have springs, so fitted that their force shall be exerted to close the scarf ring, and keep it closed.

In spring scarf slides, the two necessary things to obtain—after we have got our joint well made, and with the guiding pieces (if any) on the shutting edges—are (1) the lever peg, soundly and firmly attached to one half, and so placed and shaped that the spring is able to exert sufficient force on it to keep the two parts closed up; (2) that the spring itself shall be of a suitable shape and strength, and so placed that it will act on the peg as it should do, and yet will allow of sufficient opening of the scarf ring to easily insert the scarf. In the diagrams there are shown different shapes that these lever pegs take, and there are also several forms of springs (Fig. 6). The different forms of both one and the other are not very material, for the work in each case is the same, and will be best explained by the enlarged diagram (Fig. 5, A).

The large ellipse represents a side view of a scarf ring, jointed at one end so as to allow an opening of rather less than a right angle. If the scarf slide has to open wider than those shown in the sketches, a longer spring will be required, otherwise it would slip under the lever peg, and would then very effectually prevent the closing of the ring until the joint pin was taken out and the spring readjusted.

One other advantage of this restricted opening is that pressure is always *on* the spring, so it does not require to be fastened in its place with a screw, but will remain perfectly steady and act perfectly well if it is passed under a bar and against a stop, as in Fig. 5, B, and Fig. 6, A and B.

To restrict the opening to the usual angle, we have to do one of three things: two to the joint—viz., either let it in deep, like Fig. 5, B, or else add pieces, or a piece, along the joint, like Fig. 5, A; or, if the spring is held in its place by a screw, it may be made like Fig. 5, C—that is, with a step-like end, to prevent the lever peg going beyond its proper position.

The shutting edges, although sometimes finished flush, like Fig. 5, B, more generally have a raised piece added, which has to do two things. One is to hide the shutting edges if they do not quite meet; the other is to act as a guide to the opposite half, and lead it into its place, right in line with, and close to, the other half.

Another piece is also used to lead the two parts into a correct position one with the other, and that is shown in Fig. 5, A and C—that is to say, a tapering piece, placed on one side so that it will lead the other by fitting into it.

The position of the spikes is often changed from the central position, as in Fig. 5, A, to a place nearer the shutting edges (Fig. 5, C), and one even sees it attached to the side, where more strength can be got than if it were soldered in the middle.

We generally have the spring and spike on the back part of the scarf ring, but there is no particular advantage in that, and on occasion it will be better to reverse the positions, as in Fig. 5, C, particularly if by so doing we can get a firmer base for our spring and spike as we can when an ornament is fixed on the front.

There have been scarf slides made and patented which were intended to retain a vertical position (as Fig. 5, D and D'), the scarf passing as indicated by the arrows. They have not been much used, and seemed to require a special collar stud and peg to steady them.

Although not worn in that vertical position, it is possible to wear most of those we now make in that way, if a change is desired.

The three forms of springs (Fig. 6, A, B, and C) are such as one generally uses. The two first are kept steady by means of transverse bars or bridges, and also by pressing against a stop-piece or bead. One is grooved to fit over the lever piece.

The third is one that would be screwed or held by a nut, and the thickness of gold to be used for all forms would be about size 7 to 10 Shakespeare gauge, and should be hammered to get it nice and tough.

In conclusion, let me say that these things have to be borne in mind: (1), strength of the hinge; (2) the firm attachment of the lever peg, and a good form of same; (3) the strength and firm position of the spring at one end, so as to allow the other end to always act steadily on the peg in the one direction. The length of the spring must be properly considered too, and as for the gold it is made of, let it be rather tough; polish it bright, and also polish that part of the lever peg against which it acts, in order to reduce the friction as much as possible—a polished surface being, of course, better than a coloured, or even a gilt, surface for such purposes as this.

If these things are attended to, there should be no doubt about obtaining a successful result when making a spring scarf slide. If any difficulty is found, there is "Shop" always open for inquiry.

## HOW TO MAKE A CARRIAGE FOOT-WARMER.

BY J. L. D.

Those who drive to any extent in this bitterly cold weather will, without doubt, appreciate the comfort of a foot-warmer, and many who dabble more or less in amateur mechanics will be able, by following carefully my instructions, to make for themselves a foot-warmer quite equal, if not superior, to those which can be bought.

Some time ago I undertook the manufacture of one for myself, and succeeded fairly well, although tin-plate work is not at all my strong point. Ruminating afterwards on the various stages of my work, I thought out a plan which I imagined would produce a better finished article with less trouble.

To test my new idea I determined to make another foot-warmer for presentation to a friend, and in this I succeeded beyond my most sanguine expectations. The work was so easy that I do not see why any of the readers of Work who can solder should be without this useful article.

I write, of course, as an amateur, and in this particular branch of manufacture, a poor one, but this ought not to deter my readers from following my example. It ought rather to encourage them to find that a novice succeeded so well.

The size of the foot-warmer will be governed, to a certain extent, by the size of the tin from which it is made.

I got three sheets of strong tin, which is sold under the name of boat tin, and measures 12½ in. by 17 in. The cost is 4d. a sheet. I also got half a pound of tinman's solder: cost 7d., which is, I believe, excessive.

After much calculation I cut the ends out of a piece of tin like Fig. 1, which is a rectangle 9 in. by 7 in. The line A A, dividing the opposite sides into parts 4½ in. and 2½ in. long respectively, makes the two sides from this piece of tin.

When they were separated I placed them together and saw that they were both exactly the same size. Then, with a marking gauge, I drew lines right round each end, as shown in Fig. 1. These lines are ¼ in. from the edges. The little square pieces at the corners I then cut out carefully with the shears. I next turned up the flanges along the marked lines by laying the tin on the planed surface of my lathe-bed, having the line over the edge of the bed, and the ¼ in. flange overhanging; then I struck the overhanging part with a sort of bat, made like Fig. 3, so as to turn down the entire flange at once. With two or three strokes I made the flange at right angles to the remainder. Then I went to the next edge, and so on all round. It required some little practice to strike the whole length of the tin at once with Fig. 3, and occasionally the point or handle would hit first, but this made very little difference, as the whole flange was easily turned in the end. Fig. 3 is of oak, about 10 in. long, 3 in. wide, and 1 in. thick.

The second end was flanged opposite to the first, so that when they were put back to back the flanges turned out ; they were, in fact, right and left, and it is important to remember this before commencing to flange the second.

Having completed the ends, I had to decide upon the proper length for the foot-warmer ; 17 in., the length of the tin, I considered too long, and 12 in., the breadth thereof, I thought too narrow, so I fixed upon 15 in. as being the finished length. I therefore cut the two sheets 15½ in. long, the extra ½ in. being for turning in. I then joined the two sheets together, edge to edge, by turning down ¼ in. of the edge of one, turning up ¼ in. of the edge of the other, hooking them together, and hammering down flat. Before I turned them down, however, I cut the corners off, which served to make the joint thinner at the ends.

I then ran a little solder along the joint at both sides, making sure that it took well all the way. I had now a sheet of tin about 24½ in. by 15½ in., which I proceeded to trim so as to make the edges quite straight and parallel. I then drew lines across it to mark the positions for the bends : B B, 4 in. from the end ; C C, 8½ in. from B B ; D D, 2 in. from C C ; E E, about 8¾ in. from D D. In other words, from B B to the edge is the height of the back of the ends ; from B B to C C is the breadth of the bottom, and so on all round.

Having these marked lightly with an awl, I turned up the edges of the sheet at right angles to the body, ¼ in. wide, and with a triangular file nicked the flanges where the cross lines came—*i.e.*, at the points B, B, C, C, D, D, E, E. I then turned the sheet square up at B B, again square up at C C, and again at E E. I then laid one of the ends in the position which it was finally to occupy, having its flanges turned out, against which the back, the bottom, and the front were lying.

I then ran solder all round the end inside, being careful, especially about the corners. The other end I then put in place and ran solder round it likewise. After this I turned down the flanges of the back, bottom, and front so as to overlap those of the ends. It was necessary now to bend down the top along the line D D, in Fig. 2. I cut a piece of oak the exact length, so as to fit inside the foot-warmer, and 2 in. wide. This I placed in front, resting on the bottom, and had no difficulty in bending the top down sharply over it, afterwards springing it up for the removal of the wood. The inch from E E to the edge overlapped the back and served as a joint. I found it easy to turn in the flange of the top over the ends and solder it from the outside, making all perfectly water-tight. While soldering the overlap at the back I held a piece of wood so as to keep the edge of the tin right down to his fellow, otherwise they had a tendency to part company. It will be seen that the ends are ¼ in. inside the edges of the sides of this foot-warmer—something like the bottom of a barrel—and this is the plan which made its construction so easy to me.

In my workshop I found a piece of brass pipe, about ¾ in. diameter, screwed into another piece. I bored a hole in the top of the foot-warmer the exact size of the larger piece of pipe, and soldered in about ¼ in. of the screwed part. I then cut off a piece of the other which screwed into it, and fitted a cap to that and secured it with solder. Thus I had a screw plug which allowed of the foot-warmer being filled, and kept the water safe when it was in. A handle of wire at the same end completed the work, which has for some time given the greatest satisfaction.

## TWO ARMOURERS' HAMMERS.

BY CAROLUS REX.

To fully realise the dignity of handicraft, we must consider the methods of the painstaking and patient masters of the various mechanical arts in bygone ages, while such of their tools and appliances as have come down to us are also revelations of the honour and dignity with which such crafts were originally invested. Who, for instance, can imagine the wielders of such tools as the two hammers here portrayed to have been other than stately and eminently dignified masters of the most honourable and lucrative handicraft of their age? Truly, no mere smiths or workmen were they, but artists keenly alive to all that was graceful and beautiful in connection with their calling, as well as skilful workers in the metals over which they had the mastery. The tool roughly sketched in Fig. 1 would appear to have been a kind of planishing hammer, and is noticeable not only by reason of the extreme elegance of its ornamentation (which the writer has only succeeded in caricaturing in his very rough drawing), but also on account of the very peculiar shape of the handle, which, moreover, is covered with chamois-leather. No mere labourer or 'prentice hand could have used, effectively, this hammer. Its weight is about six pounds, and its face is a plane surface ; hence, without great skill, every blow would bruise. The head is of chiselled steel, highly wrought and exquisitely finished, and there are few modern die-sinkers who could turn out as creditable a piece of work. The piggish-looking head shown in my sketch is, in the original, that of a conventional dolphin, and on the other side there is another head—that of a lion—in equally high relief. The scroll-work is also delicately undercut, and the execution throughout is evidently that of a master hand. The other hammer, portrayed in Fig. 2, is widely different in shape, material, and treatment. It is of bronze, gilt, and damascened with wire of various colours. The shaft of this tool is also a work of art, every portion, with the one exception of the steel ferrule next the head, being beautifully inlaid. The wood is of dark colour, something like cocoa wood, and the stars of the upper part are of gold wire. Towards the lower third of the handle is an ivory ferrule, shown plain in the sketch. The lowest section is of the same dark wood as the upper, and is elegantly inlaid with gold wire in the form of scroll-work. The head, in this case, is not square, but has the section of a flattened diamond figure (see Fig. 3). At the extreme end of the shaft there is a small ferrule of ebony. According to our modern ideas, such a handle would be the reverse of "handy," as, for the matter of that, would be the head also ; but from the amount of time, labour, and skill expended upon head and shaft alike, these would appear to have been accepted patterns. It is easy to imagine one of the polished and polite, but brutal, Florentine nobles picking up such tools while lounging in the workshop of his armourer, and looking with reverence and admiration on them as evidences of the skill and dexterity of the craftsman. We can also imagine the smile of complacency which the face of the master would wear when complimented upon his efforts, as well as the scarcely veiled contempt which he surely felt for the wearers of his handiwork, whose only art or accomplishment was the ability to deal hard knocks. We might easily sermonise at great length over such magnificent tools, but must not take up more space. As the knowledge of the implements used by former craftsmen

Fig. 3.—Face of Hammer in Fig. 2.

is of great use to those of the present day, the writer gives these two ancient tools for what they are worth.

## SCREWING TACKLE.

BY DAMON.

### Screw-Cutting—Screw-Plates.

Outside threads or screws can be cut either with screw-plates and dies, or in the lathe. The screw-plates and dies have several cutting edges, and form several threads—or rather several turns of the thread—at the same time. In the lathe a single pointed tool is generally used, though not always. Modern machinery, made specially for screw-making, is generally adapted to use a modification of the ordinary stocks and dies. Screw-plates and dies can be applied either by hand or power. I propose to take the screw-plate as used for screw-cutting by hand first, as it is the simplest, and pass on to the others later.

Screw-plates are generally used for making only the smallest sizes of screws, say, from ⅛ in. downwards, although they are occasionally made as large as ½ in. One form is shown in Fig. 1. It consists of a flat plate of the best tool steel, varying in thickness from one-half to the full diameter of the screw it is intended to cut. Of course, if several sizes of holes are made in the one plate, the thickness is made suitable for the largest. This plate is drilled with a series of holes corresponding to the sizes of screws it is intended to cut. The chief fault of screw-plates is that the position of the cutting edges with regard to each other is fixed—that is, they cannot be separated or brought closer together. To attempt to cut a full thread by forcing a plate having a standard size tapped hole in it over the rod to be screwed would require the exertion of so much power, apart from the difficulty of getting the plate to start, that the rod or pin would be twisted and perhaps broken. To avoid this, several holes of different diameters are used for the one size of screw. The first one, which is of course the largest, merely marks out the thread. The others are used in succession, each one cutting the thread a little deeper, until the last makes a full thread of the standard diameter. For the very smallest sizes of screws, two or three holes are used; for the larger ones, four, or even six. The holes belonging to one set are connected by lines, as shown in Fig. 1. These lines can be cut with a chisel before the plate is hardened.

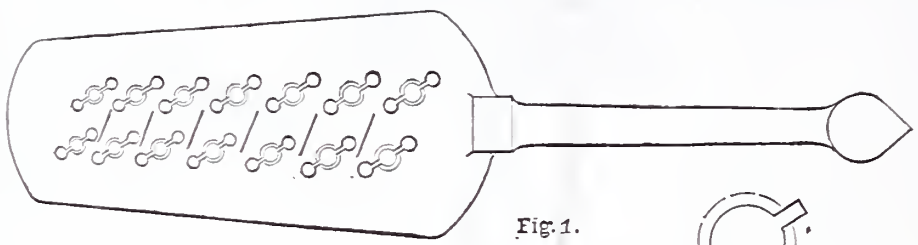

Fig. 1.

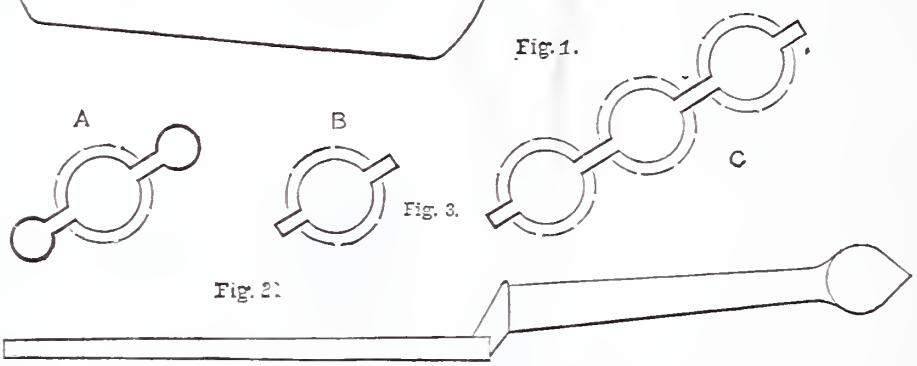

Fig. 3.

Fig. 2.

Fig. 1.—Shows Plan of Ordinary Screw-Plate. Fig. 2.—Shows Side Elevation of ditto. Fig. 3.—A, B, C, shows Three Methods of producing the Cutting Faces.

Having settled the number of holes and their diameters, they are drilled in the plate, which has been previously planed or ground flat on both sides. The holes are generally opened out slightly on the starting side, to make the thread easier to start; though the last hole of a set, which is used more as a gauge than a cutter, is not. The holes are then tapped with a special tap, called a "master" tap. This tap, as I described in my last paper, has more grooves cut in it than an ordinary tap, giving more cutting faces; but, with this exception, it is made and hardened in the ordinary way. The next step is to provide these holes with cutting edges. There are several methods of producing the cutting edges. The most usual is shown in Fig. 1, and at A, Fig. 3. Two small holes are drilled, one on each side of the tapped hole, and close to it. The three holes are then connected by cutting through the metal between them, either with a saw or a small file. This gives four cutting faces, two of which operate when the plate is moved round in one direction, and two when the motion is reversed. This method gives good cutting edges and plenty of room for the cuttings. It is not liable to break in hardening, and is easily cleaned. Sometimes the small holes are omitted, but just the notches cut, as at B, Fig. 3; while occasionally, the holes for the same size of screw are joined together by the notches, as at C, Fig. 3. This latter method has this advantage: If the piece of wire being screwed happens to break off short in the plate, a small saw can be readily used to cut the bit in two. This loosens it, and it is easily removed. The cutting edges having been made, each set of holes is stamped with the size of screw they cut. The plate is then ready for hardening.

In hardening, there is nothing special, except that care must be taken to heat the plate evenly, and avoid burning the cutting edges. Temper slowly to the usual "dark straw" colour.

Screw-plates have occasionally been made for ½ in., and even larger, screws. In these sizes three or four notches are sometimes cut, giving six and eight cutting faces respectively; only half of them, however, acting at the same time, the particular faces cutting depending on the direction in which the plate is turned. For all sizes above ½ in., however, I personally prefer the stock and dies.

The iron intended to be screwed by a plate is generally held in a vice. The point is filed a little taper to enable the plate to start more easily. After the point has been filed up, the plate is applied, the largest hole of the set being used first. Downward pressure, varying with the size of the screw, is necessary to start the thread, after which the plate moves forward by its own action. Starting the thread is the great difficulty. The plate must be kept square with the rod being screwed, or what is known as a "drunken" thread will be made. A little practice will soon give the necessary skill. Of course, the more the point of the iron rod is tapered, the easier it is to start the thread; but, then, all this tapered portion may have to be cut off after the thread is finished, which is a waste both of material and time. Besides, in short screws there is not length enough to allow much tapering, so that it is better to learn to do with as little as possible. Oil is used as a lubricant with iron and steel, but is not required for brass. The plate is worked both forward and backward, and should not be forced on too fast, or the rod will be twisted. A thread can be cut with a plate right up to a shoulder or to the head of a screw. After being used, the holes in the plate should be cleaned, or the next time it is used the cuttings may bind, and break the thread in the plate.

If the rod on which it is desired to cut a thread is steel, and is hard, or has hard places in it, it should be softened before the plate is applied, or the cutting edges will soon be worn out or broken. If the rod or pin to be threaded has been turned in the lathe, it is generally left in the chuck, the point slightly tapered and the plate pressed against it, the lathe meanwhile being pulled round by hand. The screw-plate is sometimes used as a gauge to size when a number of screws have to be cut the same diameter. The screws are cut as nearly alike as possible, and the plate is then passed over them to ensure their similarity. In small machines—such as sewing-machines and automatic tools, which are turned out in duplicate in large numbers—all the separate parts are made interchangeable, so that repairs are more easily executed. All the screws have therefore to be alike, and a screw-plate is a ready means of insuring this.

It must be noticed, by the way, in drilling the holes in a plate, that they must not be drilled the same diameter as the screw they are intended to cut, but what is known as the "tapping size" of that screw—that is, the diameter at the bottom of the thread.

## A FOLDING OR CAMPING-OUT TABLE.

BY A. CABE.

Herewith is illustrated a new form of folding or portable table, of which I, as a practical cabinet maker, have recently made a number. It is admirably adapted for camping out or for summer garden use, and indoors is an excellent breakfast table for, say, a couple of diners; or in the drawing-room, where, made of wood to harmonise with the other furniture, it is a very useful occasional or side table.

I made the first one as a small breakfast

table, to stow away when not in use, being limited for room. The arrangement and construction of the folding framework is quite an original idea, and it is given for the benefit of any readers of WORK who may choose to make it, or have it made for them.

The table in question, which I am at this minute using to write this paper, is made entirely of mahogany. It may be made of other woods, such as oak, American black walnut, or yellow pine. The table stands 29 in. high, and the top is 30 in. long by 24 in. broad. The top is made in three pieces hinged together, the central piece being 4 in. broad and the two hinged leaves being each 10 in. broad, the whole being $\frac{3}{4}$ in. thick. The chief peculiarity, however, consists in the hinged framework.

In the annexed drawings and diagrams, Fig. 1 is the table open for use; Fig. 2 the table folded, when the space it takes up is only $5\frac{1}{2}$ in. (see Fig. 3, which is the end view when folded flat). The diagrams, Figs. 4, 5, 6, and 7, show the structural parts before being put together as a whole. First of all, Fig. 6, the central frame, to which the four legs are hinged, is made. The two uprights are 2 in. by $1\frac{1}{4}$ in.; the upper rail, A, is 2 in. broad by $\frac{3}{4}$ in. thick, and the bottom rail, B, $1\frac{1}{4}$ in. by $\frac{3}{4}$ in. The breadth of this frame is 8 in., and the height over rails $14\frac{1}{2}$ in. The lower ends project downwards $1\frac{1}{2}$ in., and are rounded as shown. On the top of this frame a piece, C, is fitted, 8 in. long and $3\frac{1}{2}$ in. broad, and 1 in. thick. It is cut in at the ends, as shown in Fig. 8, to fit neatly between the uprights of the frame, and is glued and screwed down to the top of rail, A. Four screws are also put through the ends into the uprights (see C, Fig. 6). This top piece is to fix to the under-side of the central portion of the top, and the frame serves the purpose of a table pillar when so fixed (though it does not reach the ground), whereon to fix the four framed legs. One of these frames (Fig. 5) is shown. It also is 8 in. broad, and the frame part is the same length as the central frame. The leg is $1\frac{1}{4}$ in. square, tapering from the middle of its length to $\frac{3}{4}$ in. square where it touches the ground. The two rails and the hingeing stile are all $\frac{3}{4}$ in. thick, upper rail 2 in., lower rail and hingeing stile $1\frac{1}{4}$ in. broad. The hingeing stile projects downwards, and is rounded off the same as the uprights in central frame. These four frames are made in two pairs, or if the $\frac{3}{4}$ in. rails are let into the centre of the $1\frac{1}{4}$ in. legs, instead of flush on one side, then the four frames are all alike. None of the mortises are mortised through, being only 1 in. deep, and cut with a $\frac{5}{16}$ in. mortise chisel (see Fig. 4, A and B). This is a rule that holds good in all cabinet work, as distinguished from joiners' work. The joiner makes all his mortises through, and wedges them on the outside. All the frames of this table are dressed square on the edges; this, of course, is the simplest form. The rails might be stop-chamfered or cut away according to fancy, or perhaps to match some other furniture. The legs might be turned instead of square, or they might be square-chamfered. The frames being square-framed up, and nicely cleaned off and glass-papered, what remains is to hinge them to the central frame. For this I use $2\frac{1}{2}$ in. brass hinges, four pairs for the leg frames and two pairs for the hinged top. When hinged together they should be perfectly level on the top edges, both with each other and with the central plate, C (Fig. 6). I have shown the top hinged, a plain square joint being the simplest method. A much neater method, however, is what is called the Pembroke quadrant joint; in it the hinges are quite invisible, but it requires a pair of planes specially made for the purpose, besides careful fitting and working up. The hinges of the top should be sunk fully the thickness of the hinge plates, so that the leaves when folded down will show a close joint at the inner junction.

It is not necessary that the frames to support the top should fold out to a right angle; it will be enough for them to be at the angle of about 40°, as in Fig. 7. At this angle I insert, in the top on the under-side, small stop-pins $\frac{3}{8}$ in. thick, and projecting downward $\frac{1}{2}$ in. The four frames stop against these pins in the position as shown in Fig. 1.

On the ground of economy, iron hinges might be substituted for the brass ones, being only about a third of the price. The whole table is French polished, but the frames may be only varnished, and the top polished, if required to be finished cheap.

The table, as may be seen, is a very simple one for the amateur cabinet maker to construct, and anyone going in for it will have a table useful, handy, and really original in design. It is far superior to many so-called occasional tables, partly by reason of the facility with which it is reduced in size, or extended when reduced, and partly on account of the many purposes it may be made to serve.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### MITRES AND SCRIBES.

THE word "mitre," which appears to be borrowed from an ecclesiastical ornament, is used by wood-workers to express a joint which bisects an angle, giving to each piece of the material joined *equal* angles. The great majority of mitred joints require the united pieces to make a right angle, or 90°. The mitre angle, therefore, unless otherwise described, is always understood to be 45°. Picture-frames present a good illustration of mitres. As a rectangular figure must have its opposite sides parallel, it must also, of necessity, have its opposite sides equal. If these conditions are to be secured, the eight surfaces, which form by contact the four

uniting joints, must be equal in angle to each other. Taking our illustration from a picture-frame, a little consideration will show that a joint, to be satisfactory, must be at right angles to the plane of the frame in one direction, and must bisect a right angle in the other direction. Now, for mitres of the ordinary type—that is, of 45°—an appliance is, or should be, made by every worker. It would greatly help to secure a correct understanding of special requirements if the worker endeavoured to contrive any appliance to assist him. In the case of ordinary mitres, this is so well known that scarcely anyone makes the mitred joints of picture-frames and other right-angled work without the use of the mitre shooting-board.

For the rare cases in which other than right angles are required, it would not pay for the trouble to make a special block, but a very simple expedient presents itself. Suppose a triangular panel—such as that often used for enclosing the space below stairs—is to be moulded, the moulding itself may be made to assist, being parallel and fairly straight. A pencil-line can be made at the distance from the frame that the width of the moulding indicates. These lines will intersect, and a line drawn from the intersection to the angle of the frame and panel will show the mitred joint. The moulding may be cut to this line, and will then intersect properly.

In moulding door-panels, etc., it is best to cut each piece to fit equally tight, for the ends of a mitred piece of moulding are so easily bruised, and, of course, thereby shortened, that slight differences are easily overlooked in such a case. To make the best of it, put the tightly fitting pieces in last, bending slightly, so that the ends are adjusted first, and the middle pressed down afterwards. This expedient cannot be resorted to in the case of short lengths of stout moulding. Scribing mouldings is a useful method in internal angles, often used in sashes. It consists in tracing the line, which would be made in mitring, on *one* of the intersecting mouldings, and not on both. All the wood that would be covered by the moulding must be then cut away with chisels and gouges, exactly up to the traced line. This, if done properly, is equal to a mitre in appearance, and gives a slight opportunity of adjustment, which the mitre does not.

The judgment of the operator must decide which piece is to be scribed, and which left square. Scribing is often resorted to when various moulded members of different pattern are brought together, in which case a template is of great assistance.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 116.—Aublet, Harry & Co.'s Improved Instantaneous Band-Saw Vice.

The length and peculiar formation of the band saw, which, after the manner of an endless cord, is an endless strip of serrated metal, renders it somewhat difficult to hold in a fixed position during the operation of sharpening and setting. It has been reserved for Messrs. Aublet, Harry and Co., who are as yet best known by reason of the excellent quality of the French band saws that they supply, to introduce a vice of sufficient length and sufficient power of grip to hold with firmness a tolerably long piece of a band saw in its jaws while the saw itself is being sharpened and set. The vice itself, when fixed in position to take the saw-blade, is shown in Fig. 1. The jaws and, indeed, the vice itself, are 13½ in. long. The pressure of the jaws which grip and hold the vice is greatest when the handle is in the position shown. When the handle is raised, the pressure is diminished, and the saw-blade is easily removed; but when the handle is depressed, the jaws of the vice are driven into the closest possible contact with the saw, and the saw-blade is held immovable in their grip. This

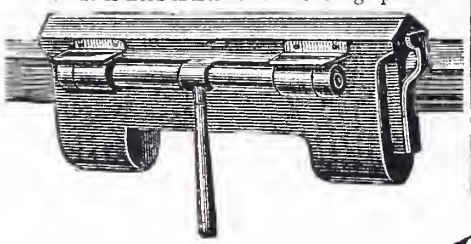

**Fig. 1.—Aublet, Harry & Co.'s Improved Instantaneous Band-Saw Vice.**

is produced by the action of the ends of the bar to which the handle is attached, after the manner of a cam, and when the pressure is withdrawn the jaw in front is apparently fixed outward by the expansion of coiled springs fitted within. At each end of the vice are guides which can be adjusted to suit any width of band saw. The price of the vice is 25s. They should be found in every workshop in which band saws are used.

### 117.—Moor's Blowpipe, for Dentists, Jewellers, Opticians, etc.

A short time since I had the pleasure of noticing an excellent retort stand, which had been invented and introduced for use in the chemical laboratory by Mr. C. G. Moor. He has now placed operative and analytical chemists, dentists, jewellers, opticians, and others under new obligations to him by the introduction of his new blowpipe, as above, which is admirably adapted for the work of brazing and hard soldering, and equally well adapted for ordinary soft soldering, as practised in the metal trades. The blowpipe itself, as Mr. Moor himself explains, "is simple in construction, substantially made, and does not easily get out of order." Its construction will be understood from Fig. 2. The frame can be easily regulated in size, and is of great intensity. A supply of gas is obtained from any gas burner by means of the upper tube, the end of which is composed of tubing of larger diameter than the other tubes, that it may be the more readily slipped over the burner. The lower tube is fitted at the end with a glass mouthpiece, through which the operator blows to increase the intensity of the flame. The lower tube is led into the upper tube near the end of the latter, and the gas and mingled air then passes through a metal tube, to which are attached metal arms in a cruciform arrangement which slides along the tube. These apparently form a support for the metal end of the blowpipe when laid down after using it. The extreme flexibility of the blowpipe, and the ease with which the flame can be directed and applied to all parts of the work, render it a most desirable appliance in the trades named above. The flame gives heat sufficient to melt silver or copper, and even platinum wire when used with hydrogen. The size of the flame can be regulated when in use by compressing the gas tube between the fingers and the palm of the hand. The price of the instrument complete, post free, is only 2s. 9d.

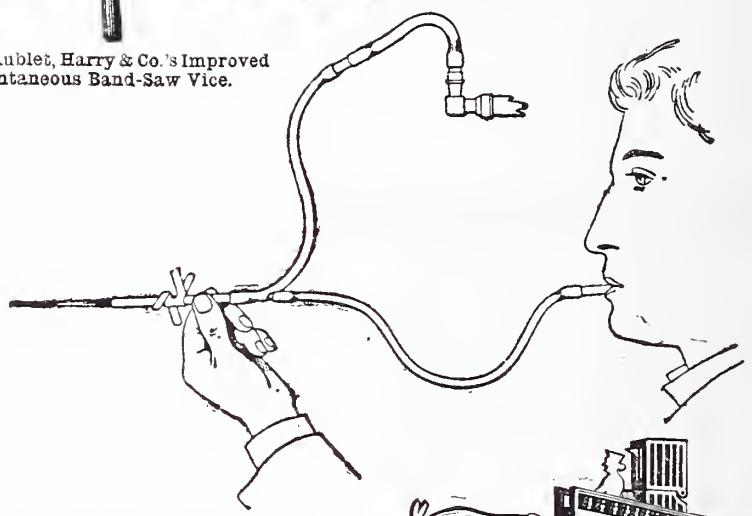

**Fig. 2.—Moor's Blowpipe, for Dentists, Jewellers, Opticians, etc.**

### 118.—Automatic Savings Bank in Fretwork.

Messrs. I. & J. Soar have recently produced some capital designs in fretwork which can be made up into automatic models, which will, no doubt, afford considerable pleasure to those who are fond of this kind of work, both in the making of the toy and in exhibiting its action after it is completed. The value of the model will be apparent from Fig. 3, in which the lower part is a

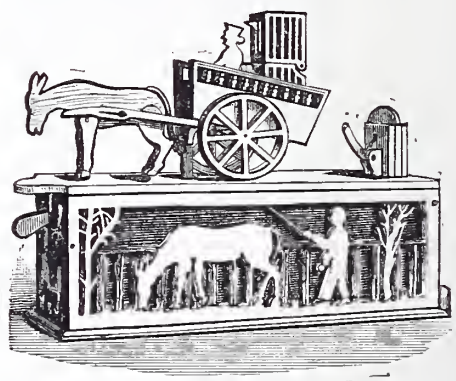

**Fig. 3.—Automatic Savings Box.**

box formed of fret-cut sides and ends and a catch in front and a door behind, which can be opened at the will of the owner. The fret-cut parts of box should be lined with plush. The legs of the donkey on top of the box are first put in position, and a penny is placed in the slot shown at end of top to the right. The catch is pressed upwards to the top of the box, and then a series of events happens in the following order: The donkey's hind legs, being released, fly upwards, the cart is tilted back, and the figure in the cart and the crate behind him are thrown backwards, the crate hits the projecting catch in front of the slot, and this, in its turn, facilitates the descent of the penny through the slot into the box. The inventors have other designs in hand which will be ready shortly. The sum charged for each sheet of designs necessary to make the model is 2s. The designs are clearly and boldly drawn, and will present no difficulty in cutting, even to indifferent fretworkers. The Editor.

# SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given.*

## I.—LETTERS FROM CORRESPONDENTS.

**Varnish.**—A WOODWORKER writes to F. P. (*Newport, Mon.*) (see pp. 699 and 702, Vol. III.):—"In the directions given for making varnish with methylated spirit, shellac, and benzoin, you say the fluid is to stand in an open vessel for a few days, then strain for use. Would not some of the spirit be lost? and as alcohol has an affinity for water, would not the spirit attract watery vapour from the air? and as few people know much about the subject, would you kindly explain the advantages of such exposure in an open vessel? I believe I have come across similar advice in making varnishes with turps, 'at that is so different to methylated spirit that by no means follows that what is good for one solvent is proper for the other. I ask not for the sake of criticism, but solely to gain information."

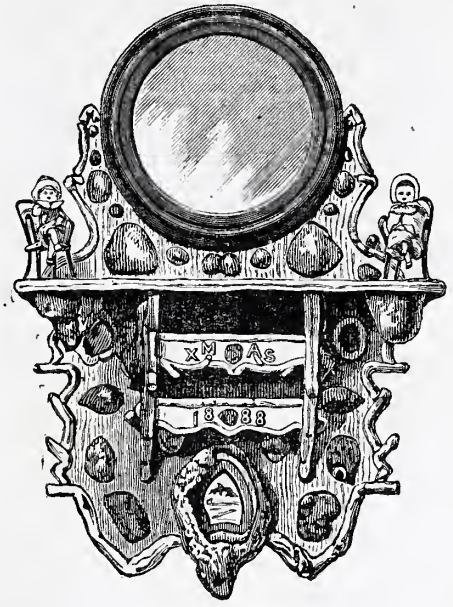
**Wire-Work — Errata.** — J. S. (*London, E.C.*) writes:—"In the inscription under my first series of sketches on p. 692, No. 148, Vol. III., where an allusion is made to Fig. 150, the word 'handle' should be replaced by 'ladle.' And in the same number, in p. 702, the word 'lever' in line 9 of my reply to R. J. (*Burdett Road, E*) should read 'sever.'"

**Testing the Accuracy of Framework.**—J. S. (*London, E.C.*) writes:—"I should like to add a trifle of justifiable stimulus to this 'storm in a tea-cup.' I have not differed in the slightest degree with J. C. K.'s methods. All I did was to protest against his assertion that the simple method was misguiding. I will leave it to the judgment of the readers whether I do not come forth from this scrape untainted, untarnished—well, that's enough. In referring to the last sentence written by J. C. K. on p. 683, where he says, 'If the opposite sides of a picture-frame are equal, and the angles square, no other test is wanted for accuracy,' I will ask if I did not claim that my method was a means to this end. It was to test the squareness of the angles for which I sent the few notes."

**Testing Accuracy of Framework.**—G. P. (*Elgin*) writes:—"I note a further communication by J. C. K. (*London, W.*), *re* the above subject, in WORK, No. 147, p. 683. He there states that 'if the square frame is winding, the diagonals being alike for length would prove the frame was not square at two angles.' That may be so; but what would be the use of, for instance, a picture-frame that was winding? How would the glass lie in the rebate? No, it would not do at all; and no man in his senses would put such work out of his hands. Euclid was referred to to prove my statements; to make an assertion is one thing, to prove the truth of it is another. It is certainly true that the laws of Euclid would prove that the same length diagonals might indicate a trapezoid; but the opposite sides of a trapezoid are not equal, and as the test, about the accuracy of which we differ, is for the squareness of picture-frames, carcases of dressers, etc., which must have their opposite sides equal, I cannot see why the properties of trapezoids have been pushed into the discussion at all. From the last sentence of his communication, I am led to believe that J. C. K. has read my former letter hastily, and has gone away with an erroneous idea of its contents. In that sentence he states a truism: I endeavoured in my note to show that if the opposite sides of a figure be equal, and the diagonals be also equal, then the angles of the figure are bound to be right angles."

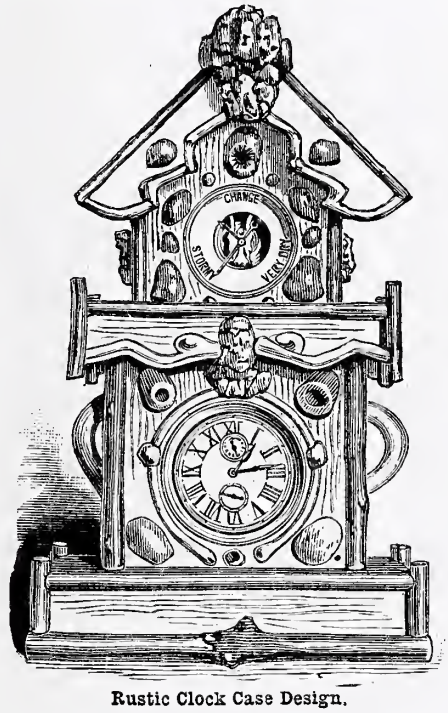
**Macramé Board.** — C. E. M. (*Birkenhead*) writes:—"Will you allow me to correct a misunderstanding in reference to a description of my macramé board, which you published on p. 420, Vol. III.? The writer of the article which appears in No. 147 on 'An Easily-made Macramé Board' mistakes the object of the attachment which I described. He supposes it to be an appliance for holding the vertical strings taut while ornamental knots (such as the Solomon's knot) are being worked on to them. If PASQUIN will turn to my letter again, he will see that that was not the idea at all. It is 'for gripping *the lace* when a long piece is being worked'—*i.e.*, when a piece of work is being made longer than the board, and has to be moved along; to obviate hooking it on to the pegs or screws, and thus dragging the lace, I place it under the spring as described. My board has no arrangement to meet the other difficulty; I have, therefore, overcome it with practice, and always hold the strings tightly between the third and fourth fingers and palm of my left hand."

**Rustic Work.**—P. H. (*Allendale Town*) writes:—"The readers of WORK may be glad of the accompanying designs for a rustic bracket and clock case, made entirely of rustic knots cut from trees and ivy branches, split or sawn up the middle. The case is



Rustic Bracket Design.

fitted with drum clock and barometer. The bracket has a spinning-wheel rim to form a mirror, and looks much nobler than it does in the drawing. It is easily made."—[We are always glad to give insertion in "Shop" to little novelties of this sort,



Rustic Clock Case Design.

and your example might well be followed by others of the thousands of WORK readers. There must be many who have home-made novelties of this order which they could photograph, and send for the benefit of brother chips and workers.—ED.]

## II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**WORK—How to Serve.**—SCHOOLMASTER.—We are glad to get your assurance that you subscribe regularly to WORK, and to hear of your anxiety to help the publication. As you cannot write articles nor draw, what you had better do will be to take two copies instead of one, and push the duplicate off to a friend or relative. If every subscriber did this, WORK would have a truly phenomenal circulation.—ED.

**Quarter Horse-Powor Engine.**—A. W. C. (*Kilburn*).—In Nos. 106, 110, 121, 125, 131, 136, 141, and 145 of WORK will be found articles on this subject.

**Phonograph.**—WIN.—Consult the indexes to WORK, Vols. I. and II.

**One-eighth Horse-Power Hot-Air Engine.**—WIN.—This subject is more fitted for an article than a "Shop" reply. You must kindly wait.

**Water-Colour Painting.**—BLUE EARTH.—A good book on this subject is "Painting in Water Colours," by R. P. Leitch, published by Cassell and Co., London, E.C.

**Nose Instrument.**—J. J. (*The Park*).—We do not undertake to give information about shaping noses in WORK. If your nasal organ does not commend itself to you, and you really cannot reconcile yourself to it, then write to some medical paper, or consult the London Directory for addresses of makers of appliances such as you describe.

**Wheelbarrow, etc.**—PROMETHEUS.—The wheelbarrow article appeared in No. 68 of WORK. Do you refer to "Lighting Arrangements in Temporary Decoration," in WORK, No. 142, by hand light making?

**Incubator Fittings.**—J. W. (*Loughborough*).—For reply to your query, see previous replies in "Shop," or consult the advertisement pages.—LEGHORN.

**Incubator.**—G. S. W. (*Dewsbury*).—You need be under no apprehension that opening the lid will interfere with the regulator. Of course, the rod, R R, will be disengaged from the adjusting screw, S, of damper, but by opening the lid you will naturally reduce the temperature very quickly. The ether vapour will then again liquefy, the mercury will rise in the short limb of tube, and, consequently, fall in the long limb, carrying with it the plunger and rod, so that by the time the lid is closed all will be clear. If, on opening and closing the lid quickly, the weighted end of damper lever is depressed, the rod will resume its normal position, when the lever can be lowered on to it, the screw, S, engaging with the top of rod as before. A joiner making a dovetailed box would make box and lid all in one, and separate by sawing, as I described. If you do not think you could manage to cut it truly, make it in two by all means. Either way, the hinges would have to be fixed to the lid proper, as you term it. It is, however, not nearly so difficult a job as you imagine. For glass tube and thermometer, see previous replies and advertisement. See that the hole in lid through which rod passes is sufficiently taper to allow it to clear on closing the lid.—LEGHORN.

**Ebonising Carved Pinewood.** — H. C. F. (*Hungerford*).—The way in which I have been accustomed to ebonise pine, whether carved or otherwise, has been to brush the wood twice over with a hot and strong decoction of logwood, and afterwards with a solution of iron (made by putting small scraps of iron in a bottle with vinegar), also applied hot; when dry, to go lightly over with fine sand-paper, and to polish with beeswax and turps. But there are other ways of ebonising; and in the back numbers of WORK you will find the matter frequently discussed. Some use a solution of copperas (sulphate of iron) instead of that above mentioned. Some mix the ingredients before applying, and add a little lamp-black or indigo to make the stain more intense. The least trouble is to buy an ebony stain, of which there are plenty in the market. As to the mountings for plush frames, you can doubtless get them from the dealers who supply photographers' sundrics. You might try Harger Bros., Settle, Yorkshire, who advertise in WORK, and who could supply you with the brass back legs.—M. M.

**Collodion Jelly.**—JELLY had better dissolve the jelly in a mixture of equal parts of pure alcohol and ether. If he adds about as much as before the drying took place, and shakes it occasionally, it will soon be restored to its original consistence. The jelly may be broken up in the bottle to facilitate the solution.—D.

**American Organ Building.**—TREWERK.—We have made inquiries, and cannot learn of any work on the making of American organs.—G.—[A series of papers are in hand, specially written for WORK.—ED.]

**Incubator.**—J. F. W. B. (*Leicester*).—(1) The incubator described in No. 143 cannot be purchased complete from any firm, it being my own design, and particulars not having been previously published. If you will send me your address, I will write to you privately. (2) Fittings cannot as yet be obtained from any one firm. Some I bought, and some I made; but if there appears a demand for sets of fittings, I will try and arrange with someone to supply complete sets or portions as required.—LEGHORN.

**Quasi-Square Turning.**—DICK 2.—Yes, this may be done, as you suppose, by cutting in a large turned cylinder several long deep slots of square section. The pieces to be turned would be planed square, so as to fit the slots in which they would be secured. In turning the several pieces of work, the cylinder edges between them will also be turned, so that when each piece has been unfixed and turned quarter-round, the moulding on the cylinder will form a guide for the tool. The three first sides can be turned so that the edge of the work will have the support of the side of the groove; but to prevent breaking down the last edge, a slip of wood must be

carefully fitted in. Perhaps, by great care and with some kinds of hard woods, this precaution might not be required. Is it a *model* hot-air engine that burnt out in a fortnight? What a shame!—F. A. M.

**Boring.**—J. W. (*Glasgow*).—Centre the wood at each end, and mark centre lines on the four sides; then fix it in a horizontal position by cramps or similar means. It will be, perhaps, advisable to have a centre line on the supports as well, so that in case the wood has to be turned end for end, it can be fixed in the same position. Then fix two bearings of hard wood for the shank of the anger to revolve in: these must be exactly central with the centre lines on the wood, one being fixed about 1 ft. from the end of the wood to be bored, and the other 1 ft. from the handle of the anger. This handle should be a good length, so as to give a good purchase in boring. The shank of the anger must be sound and truly central with the boring end. The boring can now be done by revolving the auger in the bearings; and as the handle comes up to the outside bearing, provision must be made for shifting it inwards. The anger should be withdrawn after boring 4 in., and the hole well cleaned out. The utmost care must be taken to see that it is kept in line with those marked on the outside. Should it be found going to one side, the wood should be turned, and the boring commenced from the opposite end. I have seen a tree 20 ft. long bored in this manner for a pump. It would be better to keep the wood larger than 2 in. till it is bored, for fear of getting out of truth. This method may be used for a small number, but if a large number are to be done it will be better to have a machine, as this will be a very slow and tedious process. If you require a machine, you might get one from Messrs. John McDowall and Sons, Johnstone, near Glasgow, as they are makers of wood-working machinery.—M.

**Metal for Photo, etc., Frames.**—C. E. L. (*Andover*).—Gilding metal similar to your sample may be obtained from Messrs. Smallwood & Co., Small Heath, Birmingham, or from the Berndorf Metal Works, Birmingham, who make a speciality of "Oreid" gold-coloured sheets and wires, and who will, on application for quantities, send you the current prices of the different gauges and widths. Another metal for photo mounts is called Britannia metal, and may be treated as found in an article entitled "A Novel and Artistic Photo Mount" (a piece of fancy work for engravers), pp. 141 and 142, Vol. III., of WORK. Price of metal is about 1s. 6d. per lb. There are also in the market numerous fancy and artistic designs in rolled sheet metal, and which are largely used for the purposes named above. The cheapest way of going to work for producing the ornamental material is to have a steel plate engraved with the required design, buying the sheet metal wholesale, cutting the same into sheets, and afterwards sending them to be re-rolled at a sheet metal (cold) rolling-mill. In conclusion, I may observe that nearly all metals fluctuate according to the market, so that a price-list of old date must be viewed with caution.—N. M.

**Boot and Shoe Repairing.**—J. R. (*No Address*).—The numbers of the papers since the paper on Blind Stabbing appeared are 126, 130, and 137 of WORK.

**Locomotive.**—C. W. L. (*Newcastle-on-Tyne*).—The furnace is too small for charcoal; you should have a spirit-lamp. The fact is, many of these toy locos. are frauds. I fear you can do nothing with it.—J.

**Bent Ironwork.**—J. C. (*Liverpool*).—I am preparing a series of papers on the subject for the approaching new volume of WORK, in which the various operations will be illustrated, and a number of designs given.—J. [Watch for No. 157.—ED.]

**Pattern-Making.**—F. W. (*Bradford*).—A journal devoted exclusively to pattern-making would not receive sufficient support to pay expenses. But the subject will be treated in WORK. You may get "Pattern-Making," by myself, published by Crosby Lockwood & Co., Stationers' Hall Court, E.C.—J.

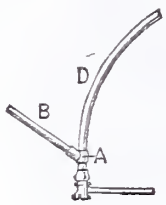
**City and Guilds of London Examinations.**—H. B. (*St. Peter's Park*).—"Elements of Machine Design" (Professor Unioni), "The Strength of Materials" (Professor Anderson), "Principles of Mechanics" (Professor Goodeve), "Steam and Steam Engines" (Jamieson), "The Steam Engine" (Cotterill), "Strains in Structures" (Professor Adams), "The Steam Engine" (Holmes), "Elements of Mechanism" (Goodeve), "Practical Mechanics" (Perry), and many others, may be studied.—J.

**Fret-Sawing Attachment for 2½ in. Lathe.**—SEAFARER.—I have been sketching one out for you, but it looks very cumbersome of wood on such a small lathe. You can make it look better by having castings made from your own patterns, but then it is not worth while to make patterns for only one machine. Altogether, I think you would do very much better to have a separate machine. There would be a good deal of work in yours, with vertical stroke and presser foot, and it is not worth while to do it all on such a little lathe. Get a No. 8 machine from the Britannia Co., then you can use the lathe to turn the little pillars and pinnacles for your fretwork brackets.—F. A. M.

**A Canvas Canoe.**—G. G. (*Llandudno*).—The following treat of canoe and boat building:—"Practical Boat Building for Amateurs" (Gill); "Yacht Designing, Yacht and Boat Sailing," by Kemp. The weight of the canoe, I should think, is about 50 lbs. I should not recommend making it shorter: that would make the lines too bluff and more difficult to paddle.—J. B. F.

**Home-made Novelties.**—HOBBYIST.—We shall be very pleased to see sketches or photographs of such articles from you or any other reader of WORK, and if they are worth putting before our readers, you will be paid the usual scale rate. You should address the Editor of WORK.—ED.

**Bicycle Castings.**—AN OLD SUBSCRIBER.—With reference to the castings for safety I have but one set remaining—namely, steering barrel, seat bracket, and bottom bracket. The bottom bracket is somewhat different from that shown and described in the articles, the only difference being that the tube, B, joins on to the curved tube, D, a little above the bottom bracket, as in the accompanying sketch, the lug, A, being easily procurable of any of the dealers in parts. I could not get more castings done under four weeks, but if the one set is of any use to your correspondent I will be glad to send them to him. A safety with 28 in. wheels need not have the wheel centres any nearer than given in the articles. There is a rage just now for a long wheel base—*i.e.*, greater distance between the wheels. A 1¼ in. solid tire of very best rubber is superior to a cushion tire, unless the latter is also of very best rubber, and the hole not over ¼ in. The bearings in the bottom bracket are Bown's knuckle-joint, and there is no necessity whatever for covering the shaft between the bearings.—A. S. P.



Bicycle Part.

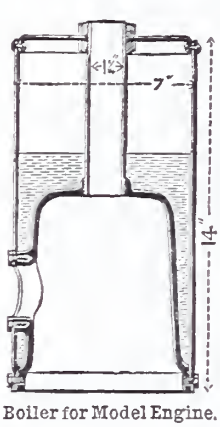
**Materials for Electric Alarum Clock.**—ANXIOUS ONE (*Rainton*).—If you will kindly turn to page 538, Vol. III., or, if you have the loose numbers, to No. 136 of WORK, you will find in the third column of "Shop," a reply to EXPECTANT, who asked where he could get materials for making coils. Any one of the firms mentioned in that reply will supply you with the bell, battery, switch, wire, and everything required to fit up the electric time alarum described by me in No. 32 of WORK. The whole will cost about 10s. 6d. at the lowest estimate, unless you make several of the parts yourself.—G. E. B.

**Tools.**—AMATEUR POOR MAN.—You complain of a tool-maker advertising in WORK, but you have placed neither name nor address on your letter. If the letters you have written to the tool-maker in question were equally faulty, we do not wonder at your getting no replies. Look into the matter from this point of view.

**Brazing.**—J. C. J. (*Gloucester*), A NEW ONE, and others.—For information on brazing, see Nos. 36, 42, 48, 50, 65, 76, and 92 of WORK.

**Vellum Drum-Heads.**—F. B. (*Clapham*).—For drum-heads in large quantities, you may apply to Messrs. Elzas & Sohnen, Barkeloo, Holland.—G.

**Boiler for Model Engine.**—A. H. (*No Address*).—How will this form suit you? It should be sufficient for your cylinder of 1¼ in. diameter and 2½ in. stroke. Shell of 7 in. diameter, Elmore copper tube ⅛ in. thick; top plate same thickness, flanged, riveted, and sweated to shell with soft solder; fire-box of cast brass, ⅛ in. thick. This avoids the difficulty of making the ring round the furnace door. It is an easy pattern to make; the casting will be turned in a lathe round the bottom, so as to drive tightly into the shell, and the mouth of the furnace also turned; joints made with red lead or soft solder, but if made with lead, boiler can be taken apart to examine. Chimney tube screwed into fire-box with red lead and joint at the top of boiler made with two nuts and red lead. If more steam is wanted, some "Field" tubes could be screwed into top of furnace, or some cross tubes might be put in. Working pressure 60 lbs.—F. A. M.



Boiler for Model Engine.

**Electro-Deposition of Iron.**—H. C. (*Surbiton*).—Unless you have had considerable experience in the electro-deposition of other metals, I should not advise you to attempt the electro-deposition of iron for an electrotype. Electrotypes are sometimes *faced* with a thin film of electro-deposited iron; perhaps this is what you mean. If so, you will not require a film ⅛ in. thick. I do not suppose you could get a deposit of workable iron so thick as this, even if you were experienced in its deposition. A solution employed in steel-facing electrotypes—that is, depositing a facing of iron on them—is made as follows:—Dissolve carbonate of ammonium in filtered rain water, at the rate of 1½ lbs. to each gallon of solution required. Suspend in this two plates of best charcoal iron, and pass a strong electric current from one to the other until a good deposit of iron is obtained on a test-plate of copper occasionally suspended in the solution to test it. When a good deposit of iron is obtained on the copper plate the copper electrotype may be substituted. This must be previously well cleaned with the usual potash solution, then rinsed in water, then dipped in a weak acid pickle for a few moments, well washed in water, and transferred at once to the iron solution. The anode surface of best charcoal iron must be seven times larger than the electrotype to be faced. A current of large volume at a pressure of 6 volts will be required. At the end of five minutes take out the electrotype, brush it with fine whiting and water, and re-immerse it. Repeat this every five minutes until a sufficient thickness of iron has been secured. Wash very carefully in boiling water, then rinse in cold water, brush dry, rub in benzine, then oil, and brush the surface with a soft brush. This is to prevent rust. This is only a brief outline of the process.—G. E. B.

**How to Soften Hard Boots.**—E. C. (*Folkestone*).—You say you "have tried all sorts of things, and they have failed." This does not give me much scope to give you any information, for if you have tried all, you must have tried the one I am going to tell you of; but still, as it is not always what is used, but the way it is used, I will tell you how. I have used it many times, and always without failure, and I think (any way, I hope) it will give you the same satisfaction. Let your boots be dry, and then give the hard parts a good drop of quite warm—but not hot—water. This, if done before the fire, will soak well in, and when you think it has gone right through, give them a good coat of neatsfoot oil, and keep them before the fire at a respectable distance, and as the water dries out the oil soaks in. As this action takes place, keep pressing the leather in different places to work it and make it mellow, and also, as this goes on, rub in one coat of oil as soon as the other has soaked in. Should this fail, let them lie by a day or two, and then repeat the above, first with the water and then the oil.—W. G.

**Boot and Shoe Repairing and Making.**—NOVICE.—In making riveted, pegged, or machine-sewn work, there is always between ¼ in. and ½ in. more stuff left on all round the bottom of the tops, or, in other words, the tops are cut longer and wider. This, because in this class of work the rivets, etc., are nearer to the centre of the sole than the sewing is in hand work, as the welt is sewn in nearer the edge, and any upper leather that is above the seam has to be cut off close to the welt. The leather is not (as you ask) subjected to any special treatment to soften it as a rule, though, if the leather is very stubborn, it can be made softer by damping it with water. All leather will form wrinkles and pipes in lasting, more especially at the toe, and here most at the extreme edge of the leather; therefore it is easier to last the first-mentioned work than it is to last hand-sewn (where there is only just enough to hold with the pincers). While lasting in the toe, only put a tingle in here and there, say, one in the centre, then the two draft tacks (one each side), and then (more particularly those you have the most trouble with—viz., "leather-lined") last up the lining first, only just knocking the tingles through the inner sole, so that they may be drawn out when you last the upper; and in doing this see that you last it smooth previous to proceeding with the upper. Then place a tingle between the centre and draft tacks. This will make or leave a pucker each side of it; these you try to tap or hammer out before putting in any more tacks. Every time you put in a tack, it should be through the top of one of these pipes or puckers, and when the toe has enough tacks in it, hammer it all round well, starting from the edge, and working to the centre of the sole, till you get to the edge of the leather. You will not get all the pipes out by this means, so you can cut a V piece out of each, and then top it down again, or the tops of them may be skived off; but, in either case, only cut to within about ¼ in. or ⅜ in. of the edge of the last, so that the rivets, pegs, or stitches have firm and solid leather to go through. By the above means light leathers can be lasted without the use of the knife at all. Perhaps the tops you used were small.—W. G.

**Kit of Tools.**—INTENDING CARPENTER.—For a kit of carpentry tools such as schoolboys could use, you cannot do better than buy of Melhuish, Fetter Lane, London, Hobday, Chatham, or one of the other tool makers who advertise in our columns.—W.

**WORK Exhibition.**—IVY.—There will be no WORK Exhibition this year, but due notice will be given in WORK of any similar exhibitions throughout the country. Secretaries should inform us.

**Mechanical Dentistry.**—AMOS.—In reply to your query as to how packing is done, there are two ways of doing this: the one is by taking your case off the model very carefully and sinking in the plaster—that is to say, you have your flask ready, and having mixed some plaster of Paris as before, pour into the bottom half level with the edge. Your case, we suppose, has been taken off the model and placed in cold water to prevent any alteration. You then take your case and sink in plaster, palate side downwards, deep enough for plaster to be half-way up the teeth; then allow to set, after which you must render non-adhesive the whole surface with liquid; then place the middle of flask on; mix some more plaster, about the consistency of cream, and fill up to the top, shaking well down while filling; then place its top portion on and put the whole under press and screw well down, and allow to stand, say, one hour, when you will be able to take your flask and place it in hot water sufficiently long enough to soften the wax on model; then you can take it apart. This you must be very

carcful about, as there is great danger in breaking away some portions of your counterpart: then pour boiling water over the whole to remove any portions of wax, as your flask must be quite clean. You then take your rubber, of which there are various colours, and cut it in slips, and place them on a hot-water plate, also to be had at a dental depôt, until they become soft. Having previously made your flask warm, which is of great assistance in packing, you then pack the rubber first well round the teeth, and then on the palate sufficient to take the place of the wax previously taken away. Then shake a little French chalk over the surface to prevent the two parts adhering; then put your flask together and place in press and screw well down; then unscrew press and open flask to see if you have sufficient: if not, add a little more, as your flask must be quite as close as with the wax. You then clamp it with an iron ring very tightly and transfer it to the vulcaniser, in which is placed about half a pint of water. The flask is then put inside and the cover screwed down quite tight, the gas lighted underneath, your thermometer placed in position and watched until it registers 315° Fahr., and kept at that for seventy-five minutes. Then turn your gas off, and allow to cool down sufficiently for you to be able to take it out, when, with a few sharp taps with a mallet, you will be able to divide your flask, and take out your case, and after washing all plaster off you finish your work with scrapers and files and finally polish, and your case is ready for the patient, for, as I before said, if the impression and model are correct so must your case be when finished. I will, later on, give a description of the process of making gold plates, and hope that the preceding letter may be of some service to parents who contemplate giving their sons an opportunity of being taught the profession, as for good workmen there is a great demand and good salaries paid; but the great secret is to place them in a good house, where they will have an opportunity of seeing the various cases made, which is necessary if the work is to be thoroughly understood.—DENTA.

**Model Engines and Motors.**—W. W. (*Cross Hills*).—If you had told us what you wished to work with the motor, I should have been better able to advise you. You will experience most trouble and expense with an electro-motor of 2 man-power, driven by current generated in a battery. You can get such a motor from Mr. Bottone, at a cost of about 50s., exclusive of battery. Electro-motors are only admissible in situations where some inconvenience would be experienced in the use of a model steam engine, a gas engine, or similar motor. Model steam engines are made by Mr. R. A. Lee, High Holborn, London, E.C. The castings for the ¼ horse-power horizontal engine described by F. A. M., in WORK, are sold by Mr. H. Milnes, Ingleby Works, Bradford. Probably Mr. Milnes will make the engine for you, as you cannot make it yourself. Have you noticed the advertisement of the Robinson hot-air engine in WORK? Perhaps this will suit your requirements. Small water-motors are made by W. H. Bailey & Co., Albion Works, Salford. Consult advertisements in WORK.—G. E. B.

**Camera.**—BUSY BEE.—The "Facile" camera, made by Fallowfield, Charing Cross Road, W.C., would suit you. All *very cheap* cameras are necessarily slightly made, and soon get out of repair, so, in the end, a more expensive one is really the cheapest, especially if it has to stand the continual vibration of a bicycle. We have had no experience with the instrument mentioned; it would be, probably, as good as might be expected for the money. Griffiths' guinea camera, or one made by Tylar, Birmingham, are both very good for the money; but you must not expect too much. You cannot do better than use Ilford plates for the negatives. Special plates are made for lantern slides. Thomas, or Mawson and Swan supply very good ones, as do many other makers. The formula for the developing solution is printed on each packet of plates. Hydrokinone developer is very suitable for this work. With any plates the following formulas will be found to answer: (A) Hydrokinone, 15 grains; meta-bisulphite of potash, 20 grains; water, 1 ounce. (B) Carbonate of potash, 180 grains; water, 20 ounces. For use, add 2 drachms of A to 5 ounces of B. Plates can be developed in this solution one after another until the developer is exhausted. A little of Judson's green dye diluted, and applied with a camel's-hair pencil, will answer very well; the other coloured dyes can be applied in the same manner. Consult the advertisements in WORK.—D.

**Small Galvanic Battery.**—J. M. (*Glasgow*).—A small galvanic battery may be constructed of copper and zinc sheet cut into strips 1½ in. by 1½ in., and immersed in weak vinegar contained in egg-cups for cells. Solder the copper and zinc strips together in pairs (except one of each kind, to form the poles of the battery at each end), and place one of each pair alternately in each egg-cup. The current from this battery will be weak, and will not be constant. If the zinc strips are amalgamated—that is, coated with mercury—and the copper strips are coated with platinum, and dilute sulphuric acid is substituted for vinegar, the strength and constancy of the battery will be increased. All batteries described in WORK are galvanic batteries, and a large number of these have been described in back numbers. Kindly refer to your indexes under the heading "Battery," and look in "Shop" for the information you require. If you had told me what you wanted the battery for, I could have given you a better reply.—G. E. B.

**Band Saw.**—ANXIOUS.—You ask if there is such a thing as a home-made band saw. You also want a description of it. I am of opinion that a band saw cannot be made at home, but I will give you a brief description of how one is made. In the first instance, the steel is rolled hot to an 18 in. gauge: it is next rolled cold to the gauge required for the saw. It is generally rolled out in lengths from 60 ft. to 100 ft. After the cold rolling has been done the steel is pared down by means of a paring machine, which is of an ingenious design, to the exact width required. After paring, the process of hardening and tempering the steel follows. This is done by passing the steel through an oven-like furnace, the speed at which this is done being regulated in accordance with the heat of the oven. The steel is afterwards passed through a fish-oil bath. After the hardening and tempering are completed, the teeth are cut in by means of a self-acting toothing machine. This machine does its work with great regularity and at a high rate of speed, cutting from 400 to 500 teeth per minute. The glazing of the saw is the next process. This is accomplished by passing the saw between two glazing wheels, emery-powder being fed on the wheels as the saw passes between them. When glazed, they are then brazed, set, sharpened, and finally tested. A good band saw should stand a strain of not less than 180 lbs. for every $\frac{1}{16}$ of its width. After reading the above, ANXIOUS will be able to judge for himself whether a band saw may be made at home or not.—A. R.

**Setting over Loose Headstock for Taper Turning.**—A. J. C. (*Carlisle*).—I have not one of the Britannia Co.'s 6 in. headstocks, and cannot, therefore, give you the dimensions of it without writing to them for it, and that you may as well do as I. Now, as to how the loose headstock is set

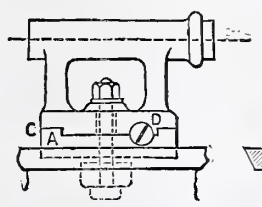


Fig. 1.

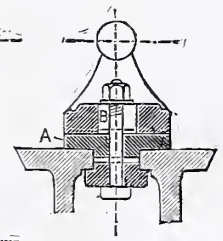

Fig. 2.

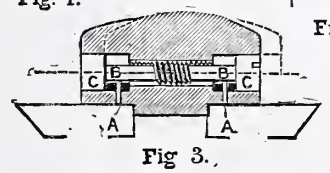

Fig 3.

Headstock for Lathe.

over for taper turning, the sketches will show how it can be done. Fig. 1 is a side view, and Fig. 2 a section through the headstock, which, you see, stands on a kind of shoe, A A, which fits between the shears in the usual way; to enable the headstock proper to slide across the bed on this shoe, the bolt-hole is elongated, as seen at B. The front, C (Fig. 1), is filed up bright, and there is an index line and scale engraved there to show central point, and also how far the headstock is thrown out to front or back. This movement is made, after slacking the holding-down bolt, by applying a screwdriver to the head of screw, D. Fig. 3 shows a way of fitting this screw. It has two heads, and is secured from moving endways on the shoe by a collar turned to fit at B B, and then cut in two, and each half secured by the pins, A, A; the hole for the screw is made first of the size B B, then enlarged with a pin-drill at each end to the size C C, then tapped for the screw-thread, which thread is then removed from the shoe, or lower half. Thus, by turning the screw the headstock may be moved upon the shoe, and then it may be clamped in any position by the holding-down bolt. A steady pin should be fitted through the sole of headstock and shoe, so as to enable the workman to return it to centre with more certainty than by means of the scale alone.—F. A. M.

**Marine Glass.**—BUTE has the tubes of an old telescope nearly complete that opens out about 20 in., the body tube being about 2 in. diameter, and wants to know what lenses are required, probable cost, and what to ask for. Lenses: object-glass, probably about 15 in. focus, and, say, 1½ in. diameter; without precise measurements of the tubes as to length, exact details cannot be given. The position of the erector must be found in the tube, then the focus of the object-glass must fall within the focus of the erector. Erector, two lenses: field, 1 in. diameter and 3 in. focus; second lens, $\frac{5}{10}$ in. diameter and 3½ in. focus; separated 4 in. apart. Eye-piece, two lenses: field lens, 1½ in. diameter, 3 in. focus; eye lens, 2 in. focus, $\frac{3}{4}$ in. diameter. These measurements are simply approximate. The cost of the object-glass will depend on quality; if an achromatic, about 5s. or 6s.; if non-achromatic, about 2s.; the other lenses about 1s. each. "What to ask for." Well, ask for what you want. If you write to a practical optician, such as Lancaster, of Birmingham, or anyone else who is pleased to accommodate amateurs, and simply say what you want, you will be supplied with the proper thing. What you need is a set of lenses for an erecting telescope, with the approximate measurement given. One thing be careful to ask—viz., how far the lenses in the erector must be separated, also the lenses of eye-piece, as the distance will depend on the exact focal length of the lenses. "How to chase a screw. I have a lathe." It is almost impossible to tell anyone how to do this. Is there no brass-fitter or mechanic in your neighbourhood? If so, ask him to show you; five minutes' seeing would teach you more than hours of reading. You will need a pair of chasers, inside and outside, which can be bought at any good tool shop. When the work is fixed in the lathe, turn rather slowly and steadily; place the chaser lightly to the work, and carry it forward at such a speed that with one revolution of the work the tool has progressed one thread. If moved forward too fast, the result will be that two or more threads will be chased on the work instead of one. It is exceedingly simple to watch one doing it, but to be able to do it is the result only of practice. As soon as the pitch is struck, then follow it up until the thread is cut sufficiently deep. If I were to write a page on the matter, I could not help you more. Practise on a piece of tubing, turning down the thread each time you fail.—O. B.

**Patent.**—J. W. M. (*Burslem*).—I believe it is generally understood that a patentee can allow his patent to lapse by ceasing to keep up his payments. The patent is granted for the fourteen years not absolutely, but conditionally, on the payment of the renewal fees.—C. C. C.

**Cycle Depôt.**—T. P. B. (*Bradford*).—It is somewhat difficult to give T. P. B. useful guidance in this matter. If he confines himself solely to repairs, it is little use keeping a stock of stampings unless he keeps a stock of all the different sorts and designs: and they are very numerous. When a repairer gets in a machine with a broken stamping, he may have a ton of stampings in stock, and not one of the pattern required. The rule is to send for a stamping or part by making a drawing of it, or finding a similar one in one of the catalogues. The only stampings that can be kept with safety are a few pair of rear-fork ends for cross-frames, a few cross-frame centre brackets, handle-bar T-pieces, clutch legs for steering-posts and seat-pillars, to fit 1 in. and 1¼ in. tubes, a few spoons for brakes, with forked ends for brake-rods, a few brake-pieces, and lugs for attaching to handle-bar; 6 in. and 7 in. crank-stampings may be kept, also finished axle and pedal pins. A small stock of weldless steel tubes should be kept, from 1¼ in. down to ⅞ in., falling by ⅛ in., some straight and curved forks, mud-guards and stays, L-pins for saddles, etc. A stock of spokes, both for safeties, ordinaries, and tricycles, is necessary, of a gauge from 10 to 15; also butted spokes, as many machines have the latter, the butt being No. 8, and the shank about 11 or 12. Cement for putting on tires is bought in hard lumps. Solution for splicing is quite a different thing, and is sold in bottles in a liquid state at most of the cycle shops. Enamel for touching up repairs is also got in bottles. Club black hard drying is very good, as it dries in ten minutes. An agent requires to keep a good show of finished parts and fittings, such as hubs, bottom-brackets, cranks, pedals, chains, saddles, bells, foot-rests, spanners, oil-cans, pouches, etc. etc. Taps and single-hole plates of the Abingdon make, which I have found to be very good, can be had: Nos. 11, 12, 13, from St. George's Cycle Co., and from several advertisers in WORK. T. P. B. should write to a few of the largest makers, sending his trade card, signifying his intention, when he will receive their catalogues and price-lists. The following firms will send illustrated lists of every possible part or fitting that goes to the make-up of the best cycles: Wm. Bown, Summer Lane, Birmingham; Hudson and Edwards, Sheepcote Street, Birmingham; Thos. Smith & Co., Saltley, Birmingham; St. George's Cycle Co., Upper Street, Islington, London; Brown Bros., Great Eastern Street, London; and the advertisers in WORK. I shall be glad to forward any further information to T. P. B., if he desires it.—A. S. P.

**WORK Volume.**—F. C. F. (*King's Cross*).—If you have applied to the publishers, as you say, and have failed to get the volume of WORK, then you should look out at the second-hand book-shops for a copy, or advertise your requirements in WORK. Some subscriber may care to sell his Volume I.; but your anxiety to possess a copy proves that the book has some increasing value.—ED.

**Altering Dimensions of Dynamo.**—O. G. (*Holloway*).—The alteration proposed by you could not secure the desired end. If, as you propose, you could take a Siemens dynamo having an armature 4 in. × 1¾ in., and field-magnets 4 in. × 3 in., and stretch them six times longer—namely, armature 24 in. × 1¾ in., and field-magnets 24 in. × 18 in.—you would not obtain any advantage whatever by the change. On the contrary, the internal resistance of the machine would be increased, and its output decreased in proportion. To increase the voltage of the current from a machine, you must wind more *turns* of wire on the armature, or run the armature at a higher speed. To get a larger output in ampères, a machine of larger proportions in every way must be built. In the series of articles referred to there are details of larger machines. Get the castings, and construct a machine according to the instructions given there; but do not presume to alter the dimensions until you know more about

the principles of dynamo construction than is shown in your letter. Your ideas respecting a dynamo to drive a motor and the motor to drive a dynamo, and an accumulator to drive a motor to drive a dynamo, are much like those of spending a penny to buy a penny to buy a pennyworth.—G. E. B.

### III.—Questions Submitted to Readers.

**** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Model Boiler.**—P. E. J. (*Gt. Bridge*) writes:—"Will any reader kindly inform me how to fix a model horizontal boiler in brick-work (boiler is 22 in. long and 12 in. in diameter, made of ⅜ in. plates)? If possible, kindly illustrate it by a longitudinal sectional drawing, showing the best way for fixing the flue, so that there will be a good draught for fire."

**Monogram.**—W. S. A. (*Kentish Town*) will thank any fellow-reader to favour him with a design for monogram for fret-saw work.

**Coffin Plates.**—H. E. L. (*Stockton*) writes:—"Could any correspondent kindly favour me with instructions how to letter coffin-plates (black ones only)? If so, I would estcem it a great favour."

**Telegraph Instrument.** — TELEGRAPHIST writes:—"Can any reader kindly inform me how I could construct a small single-needle telegraph instrument, and also the battery to work it?"

**Baize and Monogram.**—LOVER OF "WORK" writes:—"Will some reader kindly give me instructions for relaying my bagatelle board with green baize; also give me a monogram for fret-work with the initials J. W. B.?"

**Organ Bellows.**—C. W. T. (*Leytonstone*) writes:—"Will some kind reader of WORK inform me through 'Shop' the way in which the bellows suck the wind from the reeds of an American organ? I know the way the bellows are made."

**Steam Power.**—G. H. P. (*Norwich*) writes:—"Would any kind reader of WORK inform me through 'Shop' the price of a one horse-power (actual power) steam engine and boiler, and say if it is capable of driving a drilling machine and a small grindstone?"

**Electric Motor.**—C. H. (*Clerkenwell, E.C.*) writes:—"I should like to ask if any reader of 'Shop' would be kind enough to give me advice as to how to make a small electric motor? I am possessed of a fair amount of electrical knowledge, and wanted, if possible, to work it by battery power, and then the motor, in turn, to drive a small dynamo to light a small incandescent lamp."

**Carriage Building.**—R. S. (*Shelton*) writes:—"Will any kind reader oblige a beginner in carriage building with the dimensions for body-maker's tool chest, how to fit up interior, and what wood should be used for same? Also the probable cost of one ready made?"

**Mill Bills.**—W. H. J. (*Brentwood*) writes:—"Will any reader of WORK please state the process of tempering bills used by millers for dressing mill-stones?"

**Blackboard Composition.**—J. S. (*Amlwch*) writes, requesting the full address of Messrs. J. M. P. & Co. (*Nottingham*), makers of blackboard composition.

**Bagatelle Board.**—TASMON writes:—"I should be very much obliged for such information as would enable me to make a cheap bagatelle board about 7 ft. 6 in. long, giving kind of wood, cost of balls, and where they can be obtained."

**Gas Engines.**—YANKEE writes:—"Can any of your correspondents say if a gas engine has been applied as the propelling power in an ocean steamer? If not, would it not fill the bill, and he a great economy of boiler and bunker space? The gas to drive it could either be made from gasoline or from water."

**Engineering Drawings.**—BLUE EARTH writes:—"I should be very much obliged to any reader who can inform me where I can get coloured drawings, both engineering and architectural, illustrating the principles of cast shadows, etc."

**Bell.**—W. J. R. M. (*Sale*) writes:—"Will any kind reader give me a drawing of a dinner bell to hang on a bracket against a wall, so that it will swing to and fro by pulling a cord; and where to get a casting for an 8 in. bell, or a pattern for same, of the Old Church style?"

**"Great Eastern" Model.**—MODEL S. L. writes:—"I am about to build a model of the late *Great Eastern* steamship. If any reader can give me her dimensions, I shall be obliged—that is, her length from stem to stern, beam, depth from deck to keel, position of paddles, number and position of masts and funnels, and any other particulars that will be of use for making a good model, such as deck-fittings, etc."

**Monogram for Metal Working.**—WIN will thank any reader for a design for a H. E. B. monogram, to be cut out of metal.

### IV.—Questions Answered by Correspondents.

**Tatooing.**—THE JOHN WILLIAMSON CO., LD. (*London, W.C.*) write to APPRENTICE (see p. 654, No. 145), calling attention to their books on cutting, etc.

**Double Flageolet.**—C. B. S. (*Leeds*) writes to S. (*Bristol*) (see p. 702, No. 148):—"I have a first-class one, which I would sell for fifteen shillings. It has silver keys and ivory mountings."—[C. B. S. should advertise in our "Sale and Exchange" column.]

**Double Flageolet.** — B. A. B. (*Hampstead*) writes to S. (*Bristol*) (see p. 702, No. 148):—"This instrument, known as Bainbridge's Patent, was known in London some fifty years ago, and though quite obsolete as a musical instrument, may often be seen at second-hand or curiosity shops. Its tone is pleasant but feeble, and its musical value is trifling. The difficulty of playing it is greater than the effect produced."

**Oil Stone.**—M. (*Bishop Auckland*) writes to A. E. M. (*Cheshire*) (see p. 718, No. 149):—"You might try rubbing the face of the stone down on a level flag, with sharp sand and water, and finishing off with fine emery-powder. If this does not cure it, the only remedy will be to get a new stone. If you have to get a new stone, get a joiner to select one for you."

**Carpentry Kit.**—J. B. (*New Cross*) writes, in reply to C. H. J. (*West Bowling*) (see p. 718, No. 149):—"You want a list of tools for an amateur to begin doing 'household furniture' and 'cabinet making.' May I tell you that an amateur beginning has a lot to go through before he arrives at either of the two subjects he mentions. I do not think I can do better than band on the advice given me by an old chip when I was a lad. He told me to get a rule, a square (most important), a saw with teeth for general work, a medium-sized box plane, about 1 in. chisel, one or two gimlets and bradawls, a hammer, and a screwdriver. Then learn to use these well, but on something more simple than 'household furniture,' etc., to begin with. If you are quite a beginner, perhaps it may surprise you to know it is no easy matter to saw down a bit of 1 in. deal, say, 6 ft. long, making a good square cut, and right up to line from end to end, without practice. After you can use the above well, add to your list as you want them. The simple fact of wanting a new tool shows, in a small degree, that you know something of its use; and a tool, bought when required, is never money thrown away. Do not buy a lot of tools all at once—get them as you want them, and feel your way."

**Mangle Rollers.**—M. (*Bishop Auckland*) writes, in reply to LEARNER (see p. 654, No. 145):—"Holes are bored in the ends of the rollers, and the spindles—which have previously been turned—are driven in, and the roller is fixed in the lathe by the centres left in the spindles. You will require a long rest with two sockets and the ordinary wood-turning tools. You can turn them in a 5 in. centre lathe if you have sufficient power to drive it."

**Photography *versus* Painting.**—G. P. (*Elgin*) writes, in reply to A. B. (*Glasgow*) (see p. 686, No. 147):—"Oil paintings ought to be photographed on orthochromatic plates. A rapid rectilinear lens with a small stop should be used, and a suitable yellow screen fixed in front of it. The pictures should be fixed vertically, and the camera and dark back must be accurately levelled, so that the planes of the object and sensitive plate will be parallel. Care must be taken that the pictures are placed so that there are no injurious reflections from their glazed surfaces."

**Photography *versus* Painting.**—M. (*Bishop Auckland*) writes, in reply to A. B. (*Glasgow*) (see p. 686, No. 147):—"You will find instructions for copying oil paintings in 'Photographic Pastimes,' price 1s., published by Iliffe & Son."

**Indiarubber Hand.**—EDDIFRA writes, in answer to INDIARUBBER (see p. 702, No. 148):—"To receive correct information with regard to false hands, I called to see Mr. W. Marsden, the manager of Mr. Chas. Mackintosh & Co., Ltd., indiarubber manufacturers, High Street, Stockton-on-Tees. He told me they undertook to make all kinds of surgical appliances to order if they could not suit in stock; also, there is not much difficulty in making the fingers hollow—perhaps it would come in in fastening them to the hand. If you will write to them, and give them as much information as possible, or send them a model, they will be pleased to send cost. They have also branch establishments, and will give you the address of nearest branch, so you could personally visit them."

**Asbestos Cloth.**—EDDIFRA writes, in answer to JENWILL (see p. 702, No. 148):—"King & Co., Bristol, sell a cloth which they say is made of pure asbestos; also asbestos yarn spun from pure fibre. Send six stamps for catalogue."

### V.—Letters Received.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—OBLONG; W. W. (*Glasgow*); RICHMOND; R. J. H. (*Dublin*); T. H. F. (*Cornwall*); A. R. (*Scorrier*); R. T. (*Frome*); W. W. (*Balham*); NIGEL; A. B. (*Blackburn*); A. G. L. (*Stratford*); J. M. (*Dawley*); H. D. C. (*Bishopston*); A. F. (*Halifax*); J. G. (*London, W.C.*); WILLM; J. A. W. (*Waterford*); C. W. (*Openshaw*); SHOPMAN; T. W. (*Glasgow*); E. A. P. (*Cork*); F. E. B. (*Norbury*); P. S. (*London, E.C.*; G. R. (*Rushden*); J. B. (*Nelson*); J. M. B. (*Brixton*); E. J. P. (*Harrow Road*); W. T. K. (*Darwen*); T. H. (*Burnley*); HOLBORN; AMATEUR; F. T. (*Dover*); A. T. (*Sacriston*); G. M. (*London*); W. H. (*Padiham*); M. M. (*Edinburgh*); G. E. C. L. (*Ipswich*); E. T. (*Bolton*); G. W. (*Bournemouth*); J. L. S. (*Paisley*); P. R. B. (*Hitchin*); L. H. (*Everton*); BAPTISTA; W. H. C. (*Homerton*); J. L. (*Upper Holloway*; W. I. (*New Malden*); C. H. (*Ipswich*); CAWD HUD; J. B. (*Outlane*); B. H. R. (*Cardiff*); P. A. B. (*Manchester*); R. F. (*Kirkindillock*); F. P. S. (*Hemel Hempstead*); SENTINEL; G. F. J. (*Bristol.*); AMATEUR; TINKER; A. E. W. (*Purshore*); A. W. (*Lytham*); J. H. R. (*Sheffield*); G. H. *Rickmansworth*); C. K. (*Lockwood*); R. O. (*Rothe.hithe*).

## MANUALS OF TECHNOLOGY.

EDITED BY PROF. AYRTON, F.R.S., AND RICHARD WORMELL, D.Sc., M.A.

**The Dyeing of Textile Fabrics.** By Prof. J. J. HUMMEL, F.C.S. With Numerous Diagrams. Seventh Thousand. 5s.

**Steel and Iron.** By WILLIAM HENRY GREENWOOD, F.C.S., M.I.M.E., etc. With 97 Diagrams from Original Working Drawings. Fifth Edition. 5s

**Spinning Woollen and Worsted.** By W. S. BRIGHT MCLAREN, M.P., Worsted Spinner. With 69 Diagrams. Second Edition. 4s. 6d.

**Cutting Tools.** By Prof. H. R. SMITH. With 14 Folding Plates and 51 Woodcuts. Third Edition. 3s. 6d.

**Practical Mechanics.** By Prof. J. PERRY, M.E. With Numerous Illustrations. Third Edition. 3s. 6d.

**Design in Textile Fabrics.** By T. R. ASHENHURST. With 10 Coloured Plates and 106 Diagrams. Third Edition. 4s. 6d.

**Watch and Clock Making.** By D. GLASGOW, Vice-President, British Horological Institute. Second Edition. 4s. 6d.

## CASSELL'S TECHNICAL MANUALS.

**Applied Mechanics.** By Sir R. S. BALL, F.R.S. 2s.
**Bricklayers, Drawing for.** 3s.
**Building Construction.** 2s.
**Cabinet Makers, Drawing for.** 3s.
**Carpenters and Joiners, Drawings for.** 3s. 6d.
**Gothic Stonework.** 3s.
**Handrailing and Staircasing.** 3s. 6d.
**Linear Drawing and Practical Geometry.** 2s.
**Linear Drawing and Projection.** In One Vol., 3s. 6d.
**Machinists and Engineers, Drawing for.** 4s. 6d.
**Metal-Plate Workers, Drawing for.** 3s.
**Model Drawing.** 3s.
**Orthographical and Isometrical Projection.** 2s.
**Practical Perspective.** 3s.
**Stonemasons, Drawing for.** Cloth, 3s.
**Systematic Drawing and Shading.** 2s.

## FOUR HUNDRED POUNDS

### WORTH OF FRETWORK DESIGNS.

J. H. SKINNER & CO. have now ready for delivery 8,000 of their Tenth Annual Catalogue of Fretwork, Carving, and Photographic Apparatus, including Designs, Fancy Woods, Treadle and Hand Machines, Frames, Saws, Drills, Planes, Carving Tools, Bevelled-edge Mirrors, Ornaments, Fasteners, and all other requisites; also Swiss and Chinese Wood Carvings Magic Lanterns, Skates, Fancy Pocket Knives, and Scissors; Amateur Joiners' Benches and Tools; and their new **CELESTIAL ENAMEL** for decorating wood, glass, metal, earthenware, etc., the best and cheapest enamel in the market, including 54 different coloured specimens of the Enamel itself, beautifully mounted on a handsome recessed card (this card alone is well worth the amount charged for Catalogue). The above described Catalogue of 60 pages quarto, with 600 illustrations beautifully lithographed, SENT POST FREE ON RECEIPT OF FOUR STAMPS. With each Catalogue we will include, **GRATIS, One Shillingsworth of Fretwork Designs,** selected by us from our stock. As each Catalogue costs us, with postage, only a fraction less than Sixpence, our customers will thus get in value ONE SHILLING AND SIXPENCE FOR FOURPENCE.

The Season being already so far advanced, we have decided to make this extraordinary offer, in order that our Catalogues may be distributed AT ONCE, trusting to the profit on future orders to recoup us for the loss on Catalogue.

**BEGINNER'S OUTFIT,** consisting of 12-in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient Planed Fretwood and Full Instructions, price 2s. 6d., post free. 6 ft. assorted Planed Fretwood, 2s. 6d.; 12 ft., 4s. 3d., post free. Book containing 12 sheets full-size designs, 1s. Good Fretsaws, 1s. 4d. per gross.

**J. H. SKINNER & CO., W Department, EAST DEREHAM.**

*Kindly mention this paper when ordering.*

## THE DOUBLE-POINTED NAIL

*(Durrans' Patent).*

**For Dowelling Joinery of all Kinds.**

INVALUABLE FOR CARPENTRY OF EVERY DESCRIPTION.

*Particularly Useful to Amateurs.*

Machine Steel cut Nails, ¾ in., 1 in., 1¼ in., 9d. per gross; 1½ in., 1s. per gross.

Sample boxes, assorted sizes, 6d.; by post, 8d.

These Nails are a perfect protection for fence tops and trellis work, preventing the ravages of trespassers and cats.

**Malleable Iron Fence Nails.**

Sizes, 1¾ in., 2 in., 3 in., 4 in., 5 in., and 6 in., in 7 lb. bags, 3s. 6d.; per cwt., 55s.

*Durrans' Patent Nail Syndicate, Limited,*
43 and 44, Upper Baker Street, London, N.W.

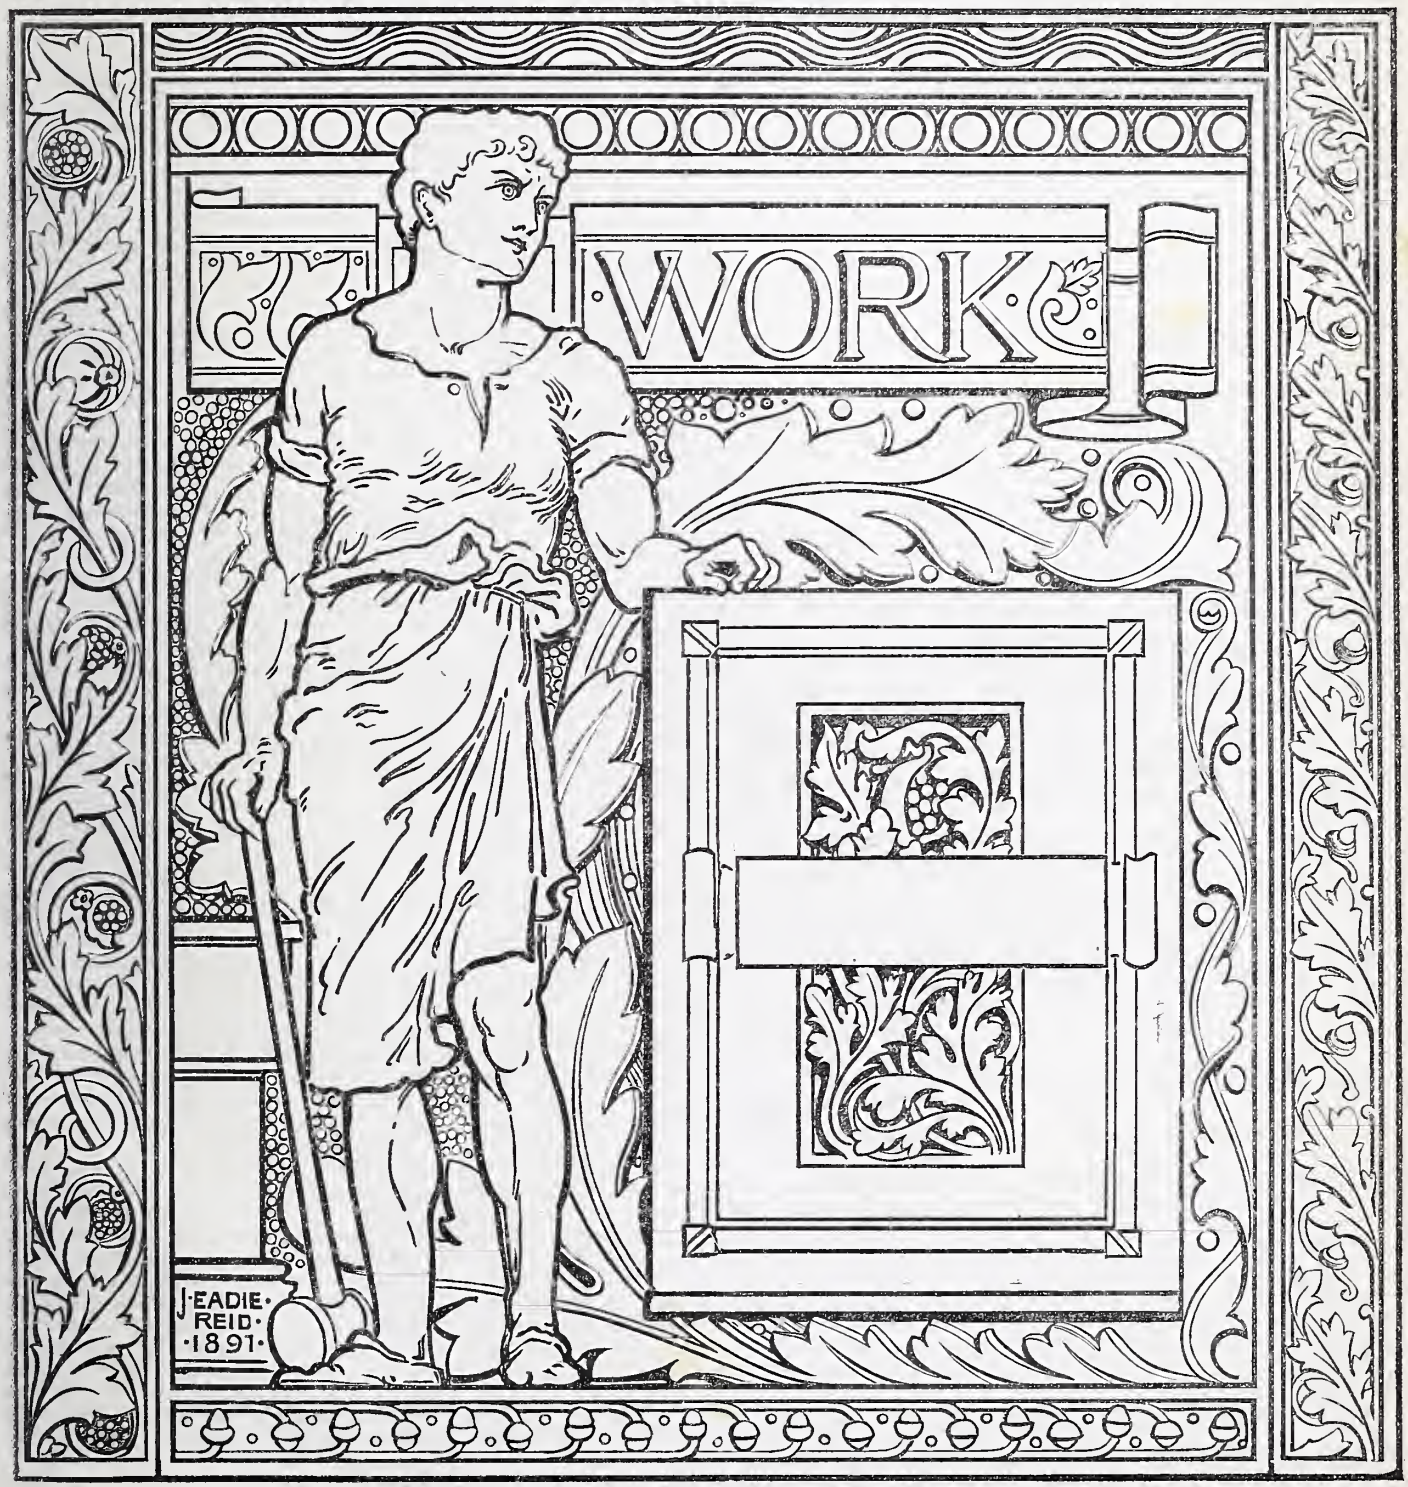
VOL. III.—No. 156.] SATURDAY, MARCH 12, 1892. [PRICE ONE PENNY.



DESIGN FOR INCISED AND EMBOSSED ART WORK IN LEATHER.

## DESIGN FOR ART WORK IN LEATHER.

BY J. EADIE-REID.

THE worker in leather, from the nature of his material, has before him an almost unlimited field for design. The wall-hangings, the tiny card-case, chair seats and backs, book-covers, etc., are all within his range. The quality of fineness in texture of the leather would of course be determined by the use for the article: pigskin, for instance, being preferable for dainty work, russet calf and such leathers answering for heavier articles.

The design which appears on the front page has been drawn specially as a cover for WORK. The block portion might be used as a card-case, while the borders will suggest many things to the worker.

The tools required are few and simple: a knife, a modelling tool, half a dozen ring tools, as shown at A in the accompanying illustration (these sizes will be found most useful), a few background tools, such as stars, shown at B, and a hammer. Having first sketched the design upon

Ring Tools (A), Star Tool (B), and Leather Ring (C), used in Leather Work.

the leather, cut the lines slightly into it with the knife, taking care not to go through. With a blunt tool then widen the cut, hammering the outer edge of the cut into the background, leaving the form standing in relief; to do this, the leather must be kept moist. The modelling and details can then be attended to and elaborated. In parts where "bossiness" is desired, it must be beaten up from the back. For this purpose it is necessary to have a few leather rings by you of varied size, as shown at C. Place the ring on the face of the form you wish raised, turn the leather carefully—seeing that the ring does not move—and beat into the ring (a blunt-headed tool will be useful for this). A paste made of bran put into the "bulge" will keep it raised; paper pasted over this again will keep the bran in place.

The design being now in a forward condition, it can be emphasised still more by giving texture to the ground. Star-shaped tools will now be found useful.

I have touched but lightly upon the salient points of the technique of this delightful craft. Experience alone will teach many of its subtleties—deftness will follow.

## THE MYSTERIOUS OR GRAVITY CLOCK.

BY CHAS. A. PARKER.

DESCRIPTION OF MYSTERIOUS CLOCK—SELECTION OF WATCH MOVEMENTS FOR MOTIVE POWER—PREPARATION OF METAL HANDS—MAKING RINGS TO CONTAIN MOVEMENTS—ATTACHING RINGS TO HANDS OF CLOCK—FITTING COVERS TO RINGS—MAKING AND FITTING HOUR HAND WITH MOTIVE WEIGHT—WEIGHTING AND BALANCING HAND—WINDING AND SETTING HAND IN MOTION—MAKING, FITTING, AND ATTACHING WEIGHT TO MINUTE HAND—BALANCING, SETTING, TIMING, AND REGULATING HANDS—PREPARATION OF GLASS DIAL—CUTTING GLASS DISC—FITTING SPINDLE TO DIAL—PLATE-GLASS DIAL—FAINTING DIAL.

THE mysterious or gravity clock which is illustrated in Fig. 1 represents a large glass plate painted with figures similar to the dial of an ordinary clock and suspended by means of a pair of silken cords, which pass through a couple of holes in the outer edge of the plate. A short spindle is cemented into another hole situated in the exact centre of the plate, upon which a couple of thin metal hands revolve, entirely free from any visible wheels or works of any kind, which thus renders the clock a source of considerable wonderment to those who are unacquainted with its manner of working, and causing the fingers of the mechanically inclined to itch with a desire to dissect its mechanism. To most people there is something singularly attractive in watching the almost imperceptible movements of a clock of this description, in which the steady and regular motion of the hands would appear to be produced by some hidden power. In the present paper the writer proposes to give sufficient manipulatory details to enable anyone who patiently and thoughtfully carries them out to construct a clock of this description which will not only go, but likewise keep accurate time.

Having thus introduced the subject to the reader, let us now turn to the details of manipulation. The first requisite will be a couple of small ladies' Geneva watch movements (without the cases), and of a uniform size of about an inch or an inch and a quarter in diameter: the movements employed by the writer measure exactly 1¼ in. Watch movements such as these can generally be obtained for about 1s. each from any local watchmaker, or, failing this, no difficulty will be experienced in buying them at a gold- and silver-refiner's in any large town, as these people frequently throw away the movements when the watch-cases are broken-up for melting. It will be necessary to pick out a couple of tolerably fresh-looking movements, which will keep going in any position when wound up. It will also be requisite to see that the motion work under the dial is complete. In order that the tyro may be certain of this, it will be found advisable to pick out a couple of movements with the dial and hands perfect, although in actual work we shall require neither. Nevertheless, by adopting this course he can rest assured that the motion work will be perfect. It is also advisable, if possible, to have the stop work in proper order, as this will prevent the possibility of the mechanism being overwound, and will likewise ensure the two hands travelling for a uniform number of hours, for without a stop work it might so happen that one hand would run down before the other, as it must be understood that they work independent of each other. The stop work of a watch will always be found attached to the underside of the barrel, but this can only be seen by first removing the dial. An experienced hand can, however, tell whether the stop work is perfect by the feel of the key upon the winding-up squares. Assuming a couple of movements of this description to have been procured, it will be necessary to just see that they are both going to time, and, with this end in view, they may with advantage be wound up and kept going until ready to be fitted to the hands.

The next proceeding will be the preparation of a couple of full-size paper plans of the hands, of which a suitable pair are shown (half size) in Figs. 2 and 3, or an alternative design of a more simple form in Figs. 4 and 5. It may be stated that the first-named are outlined from the hands belonging to the clock made by the writer, but in Figs. 6 to 8 will be found three other alternative designs, either of which may be employed according to taste. Having decided upon the design, a couple of full-size plans of half of the hands longitudinally should be made upon a piece of paper of suitable size, which is then doubled lengthwise, in order that the complete hand may be carefully cut-out by means of a pair of scissors. The paper plans, when ready, are pasted on to a sheet of thin brass of sufficient size, which should then be very accurately pierced to the form of the outline by the aid of a fret-saw with a very fine blade, after which the sawn edges are carefully smoothed to the exact curves and lines by the use of a second cut or smooth, half-round file.

For the convenience of those who are unable to do the piercing themselves, it may not be out of place to mention that Mr. H. M. Hewitt, of St. James's Square, Clerkenwell, metal-piercer to the trade, will accurately pierce a pair of hands to the design of Figs. 2 and 3 for a small sum. Having got the hands pierced, a hole should be drilled through the exact centre of the middle boss of each one, into which the hour motion wheel of an old verge watch may be soft soldered, in order to form the bearings upon which the hand may turn. Any short length of tubing of small bore would, however, answer the purpose as well, but in this case the reader might experience some difficulty in getting the hand to run perfectly true, whereas the flat portion of a motion wheel as above described will be found to afford a certain amount of hold for the solder.

The writer would strongly advise the reader not to make the hands of a smaller size than the plans given in Figs 2 and 3, as it would give the boxes containing the mechanism the appearance of being greatly out of proportion to the size of the hand, thus betraying their manner of working. Before proceeding further, the two watch movements should be made to fit tightly into a couple of half-inch lengths of thin brass tubing of sufficient diameter to contain them, both edges of each ring of tubing being accurately turned up in a lathe. An experienced hand in this case can dispense with the ready-made tubing by turning up a couple of half-inch strips of thin sheet brass and turning them into the form of a pair of rings of a suitable size to hold the watch movements, afterwards joining the two ends together with hard solder. On examining the outer edges of the movements the reader will doubtless find two or more small projecting brass pins, which have formerly served as an aid to fixing the watches in the case. By withdrawing these pins the movement may be made to fit closely into the metal ring, and when the latter has been attached to the hands, holes may be drilled through the sides of the rings, in order that the pins may be again pushed into the outer ring of the movement to again afford a means of securing it in position.

These two rings will now require to be soft soldered to the lower ends of each hand. This may be done by turning out to right angles, in either direction, the two outer leaves of the lower scrolls. Each leaf should now be moistened with soldering fluid, and then held over the flame from a Bunsen burner or spirit lamp, with a small globule of soft solder placed upon the outer side of each leaf. When the solder has covered the allotted space, the ring should be anointed with fluid in two places, and held over the flame in contact with the freshly tinned leaves of the hand until the union between the two is complete. When the ring has

been soldered to the lower end of each hand, it will be time to permanently fix the two movements in position, previously determining which shall constitute the front or outer side of each hand. Assuming the reader to have provided the central bosses with the motion wheels, as advised, it will be necessary for these to be at the back of the hands (next to the glass dial plate) out of sight. This being settled, the front of each movement should be inserted in the ring with the centre and wind-up squares just flush with the outer edge of the containing ring, and as the barrel will be the heaviest part of the watch, this side of the movement should be located at the bottom of the hand. When each one has been satisfactorily adjusted it will be well to secure them firmly in position by means of two or three small brass pins pushed through holes drilled in each ring and into the plate of the movement. In all probability the existing pins in the latter will simply require to be withdrawn and then replaced through holes drilled in a suitable position in the containing rings before mentioned. It is needless to say the dials will require to be removed previous to the movements being fitted into the hands, and great care should be taken not to lose any of the motion wheels but to keep them distinct for each movement.

A couple of small brass discs, barely $\frac{1}{8}$ in. larger in diameter than the containing ring of each movement, must now be cut to the form of a true circle, and afterwards provided with a slight projecting ring or ledge of metal, which should be carefully soft soldered on to the surface of each disc in such a manner as to transform each one into a kind of lid or cover, capable of being fitted on to either side of the containing ring of the movement, which will thus render the works accessible from either side and provide for the necessities of winding, regulating, or setting the hands.

Those of my readers who are the happy possessors of a lathe and metal-turning appliances will doubtless form these covers out of a disc of stout metal, of which the centre portion can be thinned considerably in order to lighten it, and thus provide the desired projecting ledge.

At this stage of the proceedings we shall be ready to make the two weights by which the hands are driven. For each of these mark out on a piece of sheet brass, or copper—about the thickness of a stencil-plate—a plan of the metal casing the exact shape of Fig. 9, which is drawn full size, the metal being carefully cut to the form of the outline by means of a pair of scissors, after which the sides are bent up to right angles in order to form the finished tray or casing shown in Fig. 10. Having got a couple of these trays exactly alike, proceed to fit one of them to the hour hand in the manner about to be described:—Take the hour motion wheel belonging to the movement fitted to the hour hand of the clock, and proceed to punch a hole in the end of the projecting rim of one of the trays of just sufficient diameter to pass over the tube or pipe of the motion wheel, fixing it in position by means of a touch of soft solder. This done, the interior of the tray should be moistened with soldering fluid and then filled with some solder, which may be melted over a Bunsen or spirit flame in an old spoon, and then poured into the tray, after which it is carefully trimmed up by the use of an old file. It is necessary that these weights should be neatly and carefully made, otherwise, in turning within the box, they might happen to come in contact with the sides of the latter and thus stop the mechanism. When the weight is quite ready it may be slipped on to the cannon pinion, with the minute wheel in its ordinary place. After having ascertained that the weight is quite clear of the box on all sides when the lid is on, and the set square is turned by an ordinary watch-key, it will be necessary to just rivet the boss of the minute hand on to the end of the set square (the rod upon which the cannon pinion is fitted) in order to retain the weight in its place. All that remains to be done now is to carefully float sufficient soft solder on to the under-side of the hand near to the point, in order to make it balance quite correct at the three and nine o'clock. It will, however, be necessary to see that it points true at twelve, and also that it hangs perfectly even at six. Should it happen to be a trifle out at either of these hours, it will require a little more solder on the under-side of one or other of the outer scrolls, near the point of the hand—at the same time remembering that the amount of solder must be regulated so as not to throw it out of balance at the three or nine o'clock. In actual practice the correct weighting of the hands may be said to be the part which will call for the greatest amount of care and attention. As an additional aid Figs. 11, 12, 13, and 14 show the correct position of the weight when the hand is pointing at twelve, six, three, and nine o'clock.

When the hour hand has been correctly weighted in the manner above described, so that it will balance quite equal at the four quarters of the dial, the mechanism may be wound up and set in motion, after which our attention will be called to fitting a weight to the minute hand in a precisely similar manner.

Having previously cut out and turned up another small tray similar to the one just finished, punch a small hole at the end of the projecting arm, of sufficient size to take the tube of the hour-motion wheel, which is then soldered to it in the same manner as before, after which the inside of the tray is moistened with soldering fluid and then filled with melted lead, being finally trimmed up with a file to match the previous weight. It may be stated, as a guide, that about one pennyweight of lead was used for each of these weights by the writer. The weight being ready for attaching to the movement, first remove the minute wheel, as this will not be required, and then pinch the tube of the wheel just soldered to the weight sufficient to allow of its being tightly pushed on to the cannon pinion, after which the boss of the minute hand is put on to the end of the set square, and then fixed in its place by means of a few taps with a light hammer. The weight should now be revolved in the case a few times, in order that it may be seen to be perfectly free at every part. As the weighting of the minute hand with solder requires to be carried out in a precisely similar manner in every respect to what has already been said with regard to the hour hand, it will be needless to repeat the process again. Suffice it to say that, as this hand is of a greater length than the other, it will not require so much weighting to make it balance true, and, when properly balanced every way, it can be wound up and set going in unison with the other.

It will be found that, as soon as the hand has been started, the slightest movement of the small weight contained within the case will affect the hand, and cause it to move forward. If it should happen to move in short jerks, it is a certain sign that the weighting is at fault somewhere, and this should be remedied by cutting up thin strips of solder and bending them double, in order that they may be made to clip the hand at various parts, until it can be ascertained where they are required.

The watch is very easily set to time by removing the front cover and then turning the centre set square until it balances the hand at the desired hour; and as no works or wheels or wind-up holes are visible from the outside, it renders the clock truly "mysterious," and a source of great wonderment to most people. The only drawback to a clock of this description—if it can be called a drawback—is the necessity for winding it up every day. If the two movements have been carefully regulated in unison, the clock will be found to keep accurate time, as the two weights do not affect the going in the least, because every trifling decrease of the weight contained in the box caused by its moving onward will be found to add to the weight of the point of the hand, and thus to make it move forward.

For the purpose of trying the hands until the dial is ready, it will answer very well if they are pivoted upon a small French wire-nail, or a piece of thin, round umbrella wire driven into the wall.

Now that the clock is going, it will be advisable to turn our attention to the preparation of the glass dial-plate. For this we shall require a sheet of patent plate, of sufficient size from which to cut an 18 in. circle, which must be provided with an $\frac{1}{8}$ in. hole in the centre, and a couple more about 9 in. apart in the outer edge, to which to attach the silken cords for suspending the dial. Some of my readers may consider the cutting of a circular plate of glass of the size to be a matter beyond the capabilities of an amateur, but in actual practice this is not the case, provided that the following mode of procedure is adopted. In the first place, mark out a circle of the required diameter on a piece of stout millboard of sufficient size, and then cut this to the exact form with great care. The sheet of glass is now laid on a perfectly flat surface, with the millboard disc placed in a suitable position upon it, after which an ordinary sixpenny wheel glass-cutter is rapidly run round the outer edge of the card, care being taken not to press on the wheel sufficiently heavy to cause the glass to fly. When the circle has been cut—and not merely scratched—on the surface of the glass, the four corners of the plate are then cut across diagonally in the manner shown in Fig. 15, which will thus enable the operator to break away all the waste glass surrounding the cut circle. When the glass has been properly cracked by the action of the glass-cutter, it is possible to see the crack by turning the glass over on the reverse side. The diagonal portion can be readily broken off by holding the plate with the crack level with the edge of the work-board or table, and applying a uniform downward pressure upon the reverse side to the cut, any very obstinate portions being afterwards nibbled off by means of the slots in the glass-cutter. As soon as the plate has been cut, the edge will require to be ground smooth with very fine sand, after which the three holes are drilled in the positions before indicated by means of an ordinary glass-drill, heavily weighted, and a little emery powder and oil of turpentine as a lubricant.

At this stage of the proceedings, we shall be ready for the spindle upon which the hands are to turn. This can be formed

of an inch-length of straight steel or brass wire, upon which the hands will rotate easily. This should be fitted with three short lengths of brass tube of sufficient diameter to fit tightly on to the rod, and thus keep the hands apart, at the same time allowing them plenty of freedom. When the spindle is ready, it should be cemented into the central hole of the glass plate by means of a mixture composed of Le Page's fish-glue and plaster of Paris, made into a thick paste. Any other cement can, however, be used with equal success—as, for instance, Prout's elastic glue. Care should be taken to see that the hands run true before the cement has had time to set. Fig. 16, which is a section of the glass plate and spindle, will show clearly the disposition of the various parts.

For a large-size dial like the present, a dise of stout plate-glass would be far more preferable to one made of patent plate; but if the reader intends employing a disc of this description, he will find it impossible to cut it to the required shape and grind the edges without the aid of special appliances. He will, therefore, find it necessary to obtain it finished ready for use from some plate-glass warehouse. It may not be out of place to mention that Messrs. Hard and Austin, of Great Sutton Street, London, E.C., looking-glass manufacturers and silverers, will supply a disc of the dimensions required, with three holes drilled as described, for a few shillings.

The dial, when ready, can either be painted by a professional dial-painter—for instance, Mr. Pulman, of St. John's Square, Clerkenwell, who would paint a dial of the size with Roman figures for about 1s. 6d.—or the reader can cut the figures or numerals out of white, gilt, or black paper, and then paste them on to the glass by means of shoemakers' paste, Le Page's fish-glue, or similar suitable cement, small dots being used for the minutes and stars just above the numerals, as will be seen by reference to Fig. 1. The figures shown in the above-named cut can be enlarged, if desired, and cut out of paper as above directed. Three full-size examples of Roman figures suitable for this dial are shown in Figs. 17, 18, and 19. By cutting twenty duplicates of I, four of V, and four of X, the reader will thus have a full-size set of figures ready for pasting on to the glass dial-plate. He will also require forty-eight dots and twelve diamonds or stars the same size as Fig. 20. A touch of whiting mixed with a little soap, and applied to the under-side of the glass plate, will indicate the exact position to be occupied by the figures. Nothing less than two-inch figures should be used, as they would otherwise look insignificant by the side of the hands. The white-enamelled copper letters made by Messrs. Willing and Co. would, of course, look the best for the dial, but unfortunately the price is prohibitive to a great many, a complete set of two-inch Roman figures, with dots and stars, costing the not small sum of 13s. 6d. to make.

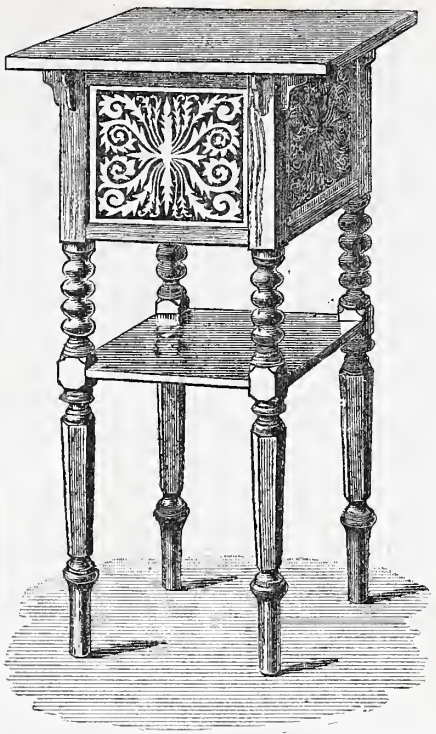

Fig. 1.—Work-Table complete.

## A TINY WORK-TABLE.

BY E. BONNEY STEYNE.

THE little table here illustrated is made from a set of turned legs, sold by Messrs. Duffy & Co., at a cost of 3½d. each in deal, 9½d. in pitch-pine for 1¼ in. size, and a trifle more for 1½ in., 1¾ in., and 2 in. respectively. The framework is of the simplest. A small cupboard is formed immediately under the top, enclosed by panels of fretwork. The quarter design given in full, if repeated to its intended size, will serve to fill either the front one only or all the sides, as the worker may wish. A shelf mid-way down the table assists in keeping the whole rigid, and increases the use of the little table. A deep drawer for work may replace the cupboard, or a drawer with a great bag pocket of fluted stuff, so frequent in old tables, may be added below the shelf.

The little table has no pretension to artistic beauty, but as an oddment, to be made in spare time at a small cost, may find favour in the eyes of our readers. The finish, whether ebony, enamel, or stained or polished, is a matter for individual taste to decide.

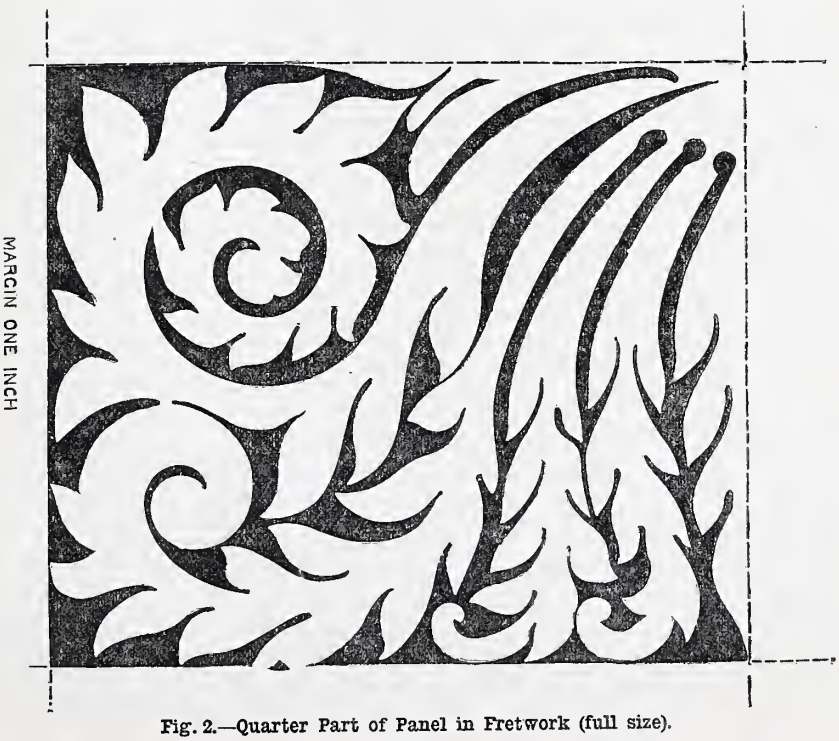

Fig. 2.—Quarter Part of Panel in Fretwork (full size).

## LENS SHUTTER ADAPTERS.

BY H. J. L. J. MASSÉ.

ADAPTERS—COST OF—SUBSTITUTE FOR—MATERIAL OF AND MODE OF FIXING—ADAPTING SHUTTER.

THE want of a ready means of adapting to my camera the three different lenses in my possession, without the delay in changing the front bodily each time, and without the expense of buying adapters (such as are sold for the purpose), led me during last summer to devise the following expedient.

In addition to the single landscape lens supplied by the makers of my camera, I occasionally use a wide angle and a rapid rectilinear lens. As the screw-threads on these where fitted on their flanges were all different, and as the flanges were all of different sizes, I found on inquiry that I should require an expensive universal lens-holder, or two separate adapters, one to adapt the wide angle and one to adapt the rapid rectilinear lens to the flange of the single lens on the camera. The estimated cost for the two adapters was about 6s., and, as I wished to economise, I took the flanges off the wide angle and the rapid rectilinear lenses, and screwed each of them on to a stout piece of leather, like that used for soling boots, which had been previously soaked a little, well hammered out, and allowed to dry. Then I chucked the flanges in the lathe, turning the leather in such a way that by removing a disc from the centre a washer of leather, bevelled on its inner edge, remained on each flange. These washers were then turned as to their outer edges, so as to fit exactly into the flange of the single lens.

Each piece of leather was cemented, as well as screwed, to its respective flange, for the sake of keeping all light out, and was well blackened with ink. Each flange is kept securely in its place on the camera front by two small brass buttons screwed on to the camera front.

I was led to adopt leather as being unbreakable, rigid, and not likely to warp. The weight of the two pieces of leather on the two flanges is practically *nil*, and the expedient has, so far, answered its purpose perfectly.

So far for the lenses. I next approached the subject of shutters. The one I use is a roller-blind shutter, a form to which I am peculiarly devoted, as it

gives the right exposure to the foreground. I had fitted it originally to the single landscape lens, and want of room prevented me from buying another for the rapid rectilinear lens; but, finding that the hoods of the two lenses in question differed so slightly in size, I slipped an indiarubber band on to the hood of the rapid rectilinear, and the cork back of the shutter fits on like a glove. By turning a washer of boxwood, or other hard wood, to fit the hood of the wide angle lens, the same shutter would do for that also; but with this lens I have, up to the present, required cap exposures only, as I have only used it for photographing interiors.

## CIRCULAR OR CURVED PANELLING.

BY "CHOPSTICK."

INTRODUCTION—CORRECT MEASUREMENT—SETTING OUT RAILS AND BLOCKS—GLUING UP AND CLEANING OFF INTERNAL CURVES—CONCLUSION.

I DO not intend this paper for the experienced joiner who is employed in a large establishment, where machinery for every purpose is at hand, and who would smile at the thought of doing a simple job by such primitive means, but rather for the small shop in the country where such jobs are few and far between, and where machinery is conspicuous by its absence. In such places it sometimes happens that a new counter front has to be made, and, instead of the common square corner to the panel work, it has to be rounded off, which, to say the least, looks decidedly better. When I was young and in the country ("about five miles from nowhere," we used to say), we had a bar in a public-house to fit up in this way, and I was ordered to make a piece of panelling for the front and a piece for the end, and fill in round the circle with narrow pieces of match-boarding. This did not suit my fancy at all, so I set my wits to work and made it in the way I am about to describe. The first thing to do is to take the

*Correct Measurement.*—To do this, you must draw on the shop floor a plan of the whole affair, with a circle at the corner of the sweep you intend having; then measure carefully round the outside of the marks. If this is not done correctly, when you come to fix the panelling you may have to cut away the outside stiles, and that would spoil the look of the whole job.

*Setting out Rails and Blocks.*—This will be done exactly as though it were a piece of straight panelling, but, if possible, arrange it so that a muntin will come at the extreme end of each straight part, as shown in Fig. 1: and if the circle is a large one, so as to require a muntin in it, it must come in the centre as shown, but it is much better for one panel only to bend round the curve. When the rails are set out and mortised, cut away between the two mortises which come close to the curve, so as to leave only a small piece of the thickness of an eighth of an inch. This piece is shown at D (Figs. 1 and 3). Then make a block as A (Figs. 1 and 4). The outside must be cut to the same curve which the finished panelling is to have, and at the points where the quarter circle ends cut a notch exactly the same depth as you cut out of the rails; these notches must be at right angles with one another, as shown by dotted lines in Fig. 4 (I omitted to say that the block should not be so deep as the rail by half an inch; thus, if the rail is 7 in., the block must be 6½ in.). A rabbet must now be cut round the circle at the top edge of block, three-eighths of an inch on, and the same depth, and a piece of wood an inch wide and three-eighths of an inch thick bent round and glued and nailed there. Now you place the block on the bench, and fix the front or longest part of the rail to one of the notches which are cut in the block, with a screw as shown in Fig. 1, then carefully bend the rail round, and fix the other side the same. If it comes correct—and it should do if you have followed my instructions closely—you can now unscrew and glue the block, then fix again in the same way with screws, and put on one side till dry.

The next part to proceed with is the gluing up, but before doing this cut off the inside of the groove for the panels on the

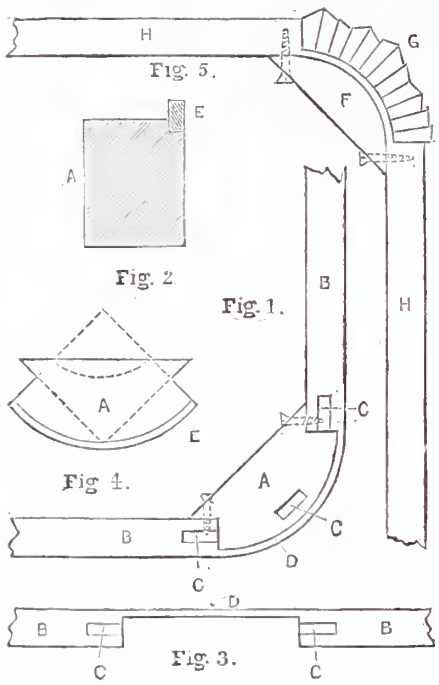

Fig. 1.—Plan of Circular Panelling. External—A, Block; B, Bottom Rail; C, Mortises; D, Part of Bottom Rail not cut away. Fig. 2.—Section of Block A—E, Thin Piece bent round to fill up to Panel. Fig. 3.—Bottom Rail cut but not bent. Fig. 4.—Plan of Block A. Fig. 5.—Plan of Circular Panelling, Internal—F, Temporary Block for Template; G, Blocks glued on to make up Rail after being bent; H, Bottom Rail.

two muntins into which the circular panel is to fit, so that this will go into a rabbet instead of a groove, then glue and wedge up in the usual way. This being done, you can proceed to put in the circular panel, and you will see the reason why the muntins are rebated instead of grooved, as, if they were done the latter way, it would be an impossibility to get the panel in. You will also see the meaning of the raised piece (E, Fig. 2) on the block, which is to make up the proper thickness outside of the panel. The panel can now be nailed into the rabbets from the back, as it will be found to bend round with a little persuasion, and it is as well to fix it still more firmly with thin curved pieces cut to fit it inside, and nailed to the blocks. The whole can now be cleaned off, remembering to take a little extra care round the curve; and, the moulding being put in, the job is finished, and if properly done cannot fail to be satisfactory. If you thought proper, the block could be cut away as shown in dotted line in Fig. 4, but it would take away part of its strength, therefore I do not recommend it.

The above, you will of course understand, refers to panelling with the circle outside. I will now show you how to proceed when the circle is inside, as shown in Fig. 5. This is done in the same way as the other as far as setting out, etc., is concerned, and the rails must be cut out in the same way, only the part left on to form veneer will have to bend the opposite way. We must also make a block, as before, but it will require no notches, only it will want carrying on for an inch or two in a straight line beyond the quarter-circle, so that the screws for fixing it can be screwed into the solid rail beyond the veneer. The block in this case will only be required temporarily until the glue has set, as it will be on the face side of the panelling. Having got all ready, screw the block in position as shown at F (Fig. 5), then fit blocks all round as shown at G, and glue them so as to fill up tightly and firmly to the proper thickness. This, after the glue is set, will effectually hold the rails to the proper curves; and as all the rest of the work will be the same as I have explained above, with the exception that the panel and mould have to be bent the opposite way, I need not go over it all again, as you will be able to manage one as well as the other.

In conclusion, I may say that the latter way of filling up the part cut away is nothing new, as it is the way adopted in making good staircases, with well-holes, to fill up the string-board after bending, and is much better for this purpose, as well as for the panelling, than cutting the curve out of the solid, as it shows the grain of the wood all round, which the latter would not, as well as being stronger.

If there are any details which I have not explained clear enough, I will do so, if called upon, in the "Shop" columns.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### FIXING SHELVES.

THESE papers would be very imperfect if some attention were not bestowed on fixing of a simple character. To fix a shelf is regarded by the ladies as a proof of mechanical ability and of helpfulness.

We will suppose a recess and a board of ample length destined to become a shelf. The following plan will lead to success:—First take the angle of one end of the recess. This can be done with a two-foot rule, opening it to fit the angle, and marking the same on the board. Secondly, measure the length of the recess, and mark the same on the back edge of the board. Thirdly, take the angle of the other corner of the recess as the first was done, and mark in like manner on the board, as before. If the board is now cut to the lines, it will fit. To avoid any disappointment which might arise from imperfect plastering, rendering the angle uncertain, it would be better to decide the height, and fix a ledge or bearer of wood to the wall. These bearers of 1 in. wood, about 3 in. wide, and length according to the width of the shelf, are usually nailed to the wall—if it is a wall, and not a lath-and-plaster partition. There is some risk of failure, which cannot be avoided. The nail may come in contact with a very hard brick, and refuse to be driven. In that case, either drill or chisel with a small

cold chisel a hole in the wall, cutting it deep enough to hold—say, at least 2 in. Then cut a piece of deal about the right size, but taking care to chisel it somewhat in winding. The hole may be slightly undercut, and the plug driven in with a hammer. When driven sufficiently, no more blows must be administered, for when the plug will go no further, additional blows only tend to loosen it. Any surplus block must be cut off with a saw, taking great care to avoid spoiling the wall surface beyond that which the bearer covers. In most instances, however, it will be found that a good nail, straight and stout, will go into most brickwork that has been plastered over; but avoid slender nails, and bore holes in the bearers for the nails, for it is essential that the nail should hold more tightly in the brickwork than in the wood. But it may be that our wall (in appearance) is but a lath-and-plaster partition. Then the position of the upright timbers must be ascertained, and the bearer screwed or nailed to them. By all means use screws if possible. To find out where the timbers are, tap with the knuckles or very gently with a hammer. The difference of feeling and of the noise will soon indicate the position. Do not strike hard, or a rattling noise will remind you that you are knocking off the "key" or overhanging plaster from the inner surface of the laths. If you do much in that way, the plaster will soon be loose in front, so be gentle, and use screws instead of nails. When one nail or screw is inserted in one of the bearers, test with a spirit-level. When satisfactory, put in the rest of the nails or screws; then put the shelf in, if properly cut. It will almost support itself. If loose, get a helper to hold it at the free end, or prop it up; test with spirit-level, and mark for the other bearer, if necessary. Remove the shelf, but if it fits rather tightly, avoid doing so, as it will most likely damage the wall. If the ledges have been cut wide enough, they can be fixed without the removal of the shelf.

Only one other difficulty may occur—the partition may be covered with patent plastering, in which case it will be difficult to tell where the timbers are. But there is this compensation: that screws will hold fairly well in the plaster itself, independent of the timbers.

### Building up and Putting Work Together.

Amateur work depends very much upon the care with which the various parts are united. Structures which professionals make in few parts, of considerable size, the amateur must construct in smaller parts, and unite these together afterwards. We will look at a few of the methods adopted for this purpose.

There is the plinth and cornice mode of uniting parts, capable of being used even more frequently. In this a pair of frames are made, usually dovetailed together, though the back rail is often grooved to the end pieces and blocked. These frames, forming the vertical surfaces in the finished work, have affixed to the edge of each a piece of wood, moulded, or suitably finished. The inner angles of these frames, not being visible, are secured more firmly by means of "blocks." These are merely pieces of wood, prepared in any length to the proper angle. In this case, two adjacent surfaces must be at right angles. In order to distinguish these prepared sides of the wood, the opposite angle is planed off, and the strip is cut into suitable lengths. These "blocks" may be used in any interior angle not exposed to sight, and are most useful and effective.

Dowels, used in this union of parts, serve to prevent sliding motion, and to secure the proper position of each portion of the work. Ordinary wood screws are frequently used in conjunction with dowels. Table tops are frequently fixed with screws inserted obliquely through the inner sides of the frames; such fixture ought not to be permitted where any probability of shrinkage exists. A better plan is to make a mortise in the frame and screw a block, which has a projecting tenon, to the under-side of the table top. It is quite useless and unwise to ignore the fact that wood will shrink, even after considerable time has elapsed since its being made into furniture, unless the material has been kept for a long time in a dry place. No expansion, through damp, need be feared in furniture; but outside work, such as doors and sashes, if made of well-seasoned wood, will often need "easing" in damp weather. This shows that panels for exposed situations should not be too wide, and that ledged or clamped work is unsuitable.

The use of mouldings to conceal the junction of parts has much to recommend it to the amateur. These mouldings should be fixed to one of the parts, and preferably to the part most exposed to sight, the part fitting loosely into the moulding not being so good in appearance.

Bolts, screws, thumb-screws, dining-table fasteners, studs and plates, hinges with loose pins, and pivots in lieu of hinges, are all means, provided by the ironmonger, by which parts of a structure may be connected to each other, but they ought not to be depended upon without means of adjustment made by the worker; they are, in most cases, fixtures capable of spoiling the work by careless adjustment.

I know that this will be regarded as a reason for planning out the whole work carefully before attempting construction. Be it so. No better lesson can ever be given than one which most convincingly sets forth the value of careful planning as a precursor of successful construction.

## HOW TO MAKE A RESONANCE BOX.

BY AN OLD TEACHER

Although the zither is universally admitted to be one of the sweetest of all stringed instruments, it is also one of the least noisy—indeed, its tones are so "sweetly subdued" that it becomes imperative to augment them artificially. For this purpose we make use of a simple but very effective contrivance, known as the resonance box. This appliance consists of a shallow closed box, either supported upon legs—when, to all intents and purposes, it becomes a table—or upon short claws or knobs, as shown in the diagram, when it is placed on another table when in use. As its only use is to augment the tone and volume of the instrument, neither form has any advantage over the other; it is simply a matter of taste. For those who have ample room the table form has the preference, as, except on the top, it admits of any amount of ornamentation or enrichment, and thus forms an elegant addition to a drawing-room; while those who are cramped for space naturally prefer the more portable form, which may be placed aside when not in actual use. There is not much to describe about this article, and the veriest tyro will have no difficulty in making a thoroughly serviceable one. The sizes given in the illustration need not be taken as hard and fast, as, so long as the box or table is longer and wider than the zither, and at least twice its depth, the exact size is immaterial. The table shown in elevation in Fig. 2 represents one made for a pupil some years ago by the writer, and may be taken as a fair type.

The materials used were as follows:—For the sides and ends, ¾ in. pine; for the top and bottom, ½ in.; the legs were already on hand.

For the top a nice piece of wood must be used, free from knots or shakes, while that

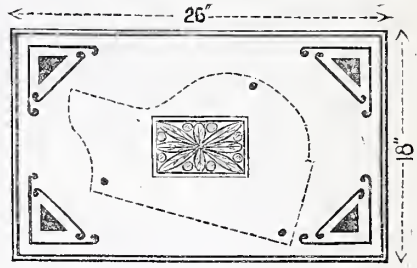

Fig. 1.

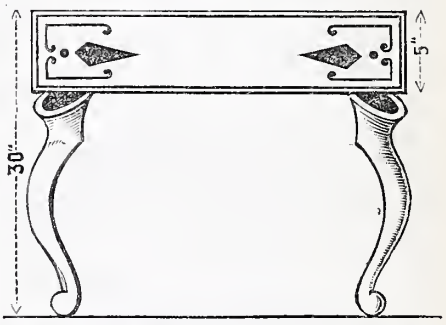

Fig. 2.

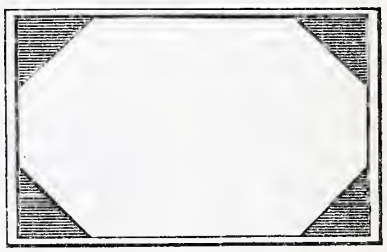

Fig. 3.

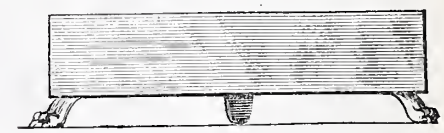

Fig. 4.

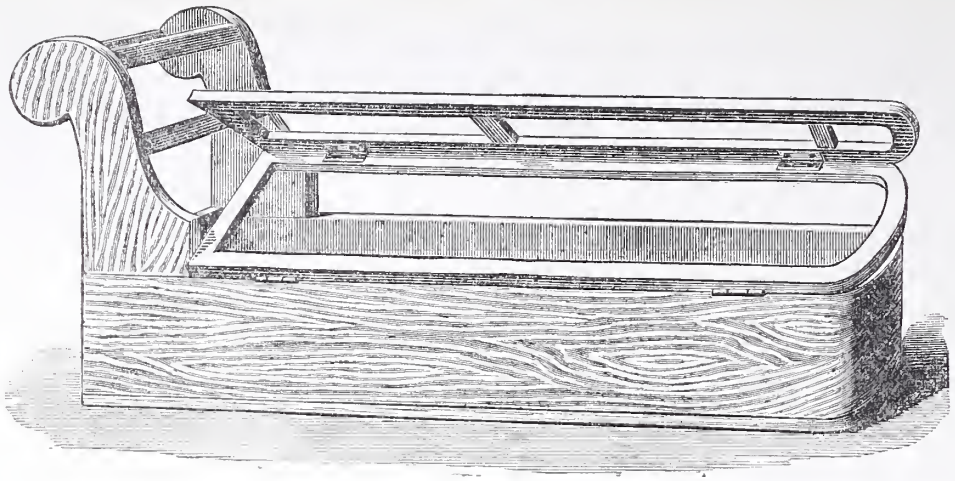
Fig. 1.—Plan. Fig. 2.—Elevation. Fig. 3.—Inside of Box, showing Method of fixing Legs. Fig. 4.—Alternative Form for use on Table.

used for the bottom should approximate to it as nearly as possible. If there is any best, let it come at the top. In the centre of the latter a sound-hole must be cut of any approximate shape or size, but this may be filled in with a fretwork panel. Instead of one large sound-hole, two, three, or four smaller ones may be made, but in this case care must be taken to keep them clear of the places where the "legs" of the zither will come. The dotted outline on Fig. 1 shows the position of the instrument on the table when in use, and the "legs" are shown as black dots. Pine is the only wood suitable for the top and bottom, but any kind of *hard* wood may be used for the sides or ends. Fig. 4 shows the alternative form of the

resonance box, but the construction is precisely the same, as the short legs should be continued up to the top, as in the case of the others (see Fig. 3). Probably the most logical mode of finishing would be to polish, but the one which formed the prototype for this article was simply ebonised and picked out with gold, the fretwork panel being gilded, as were the lines shown in the cut. The precise amount of ornamentation may safely be left to individual taste, but do not overload it, as, after all, such a table should serve as a foil for the instrument placed upon it, and may, therefore, be kept as severely and classically plain as you please. It ought to be noted that when made for use upon another table, three legs are preferable to four, as stability is thereby ensured, which is a matter of considerable importance. It might also be worth while to combine a music desk or stand, which no one would be at a loss to know how to do. As a rough guide as to height (when made as a table), you may remember that, when seated, the zither should be on a level with your *elbow*.



Reversible Lid for Box-Ottoman Couches.

## A REVERSIBLE LID FOR BOX-OTTOMAN COUCHES.

BY JAMES SCOTT.

AMONG my many trade acquaintances, I number one who is possessed of much inventive talent of a simple nature. One of his "ideas" is embodied in the article illustrated herewith. Upon noticing the paper "How to make an Ottoman Couch" (page 728, No. 97, Vol. II.), it occurred to me that many readers who might have adopted H. Hinge's practical and plain instructions, or had intentions of making such a couch in the future, would prefer to fit it with a lid of the peculiarly useful kind which is shown in the annexed sketch.

Its object and utility must be apparent to all workmen who will examine the drawing. There are two framings: the top one being covered in a similar manner to that lucidly described by H. Hinge in the above-mentioned paper; and the under one being always uncovered, precisely as it is here shown. The lower one is hinged to the couch on one side, it matters not on which, while the upper one is similarly attached to the upper surface of the lower one, on the opposite side. A handle is fitted on the front of the top frame, and another to the back of the lower frame. Whether the article be placed in an apartment with the scroll on the left-hand side, or on the right-hand side, the lid can be opened: in one case by raising only the upper framing, and in the other instance by raising both together.

Only an extra framing, therefore, is needed, in addition to the various parts spoken of by H. Hinge, in order to convert the couch into a reversible article. I do not know of a more *useful* couch than this "box-ottoman," as it is dubbed.

It may be well for me to add that my sketch is taken from a sheet of drawings of this particular couch, which I drew and printed for its maker, who is also the inventor of its lid, a year or so ago; and is not traced, as might at first appear, from H. Hinge's drawing. A note to the inventor and manufacturer, Mr. J. Trevallion, 14, Henson Street, Old Street, E.C., will elicit any further particulars relative to this article; and a request for a sheet of illustrations with prices indicated thereon, for anyone who may wish for such, will meet with courtesy.

I need only add that if any amateur who tries his hand at making this reversible lid finds that he cannot manage a rounded end to it, he can make it square, but he must bear in mind that the box must be square also.

## AN OAK TEA-TRAY: HOW TO MAKE IT.

BY ALEXANDER MARTIN.

THE days when highly decorated iron tea-trays were a necessary in every parlour are past and gone, but the fashion seems to be setting in again, though, instead of iron, wood is the material employed in their manufacture. Oak tea-trays are so easily made, and are so pretty and useful when they are made, that the following lines may be interesting to most of the large army of woodworkers.

The general view in Fig. 1 gives an idea of the nature of the tray, and a section of the edge, or rim, is given full size in Fig. 2. From these it will be seen that the sole of the tray is the foundation, and the rim is mitred on it. In selecting the wood for the sole, it should have as little heart in it as possible, so as to reduce in the greatest degree the tendency to "cap." The moulded rim planted across its ends will act to a certain extent in keeping the sole flat; but every precaution ought to be taken to ensure the sole keeping as level as possible.

The handles consist of three turned pillars each, two screwed to the rim and sole and a cross-piece between them. Fig. 3 shows nearly full-sized drawings of these turned pieces, the dotted lines indicating the portions which are hidden, but necessary for constructing the handle.

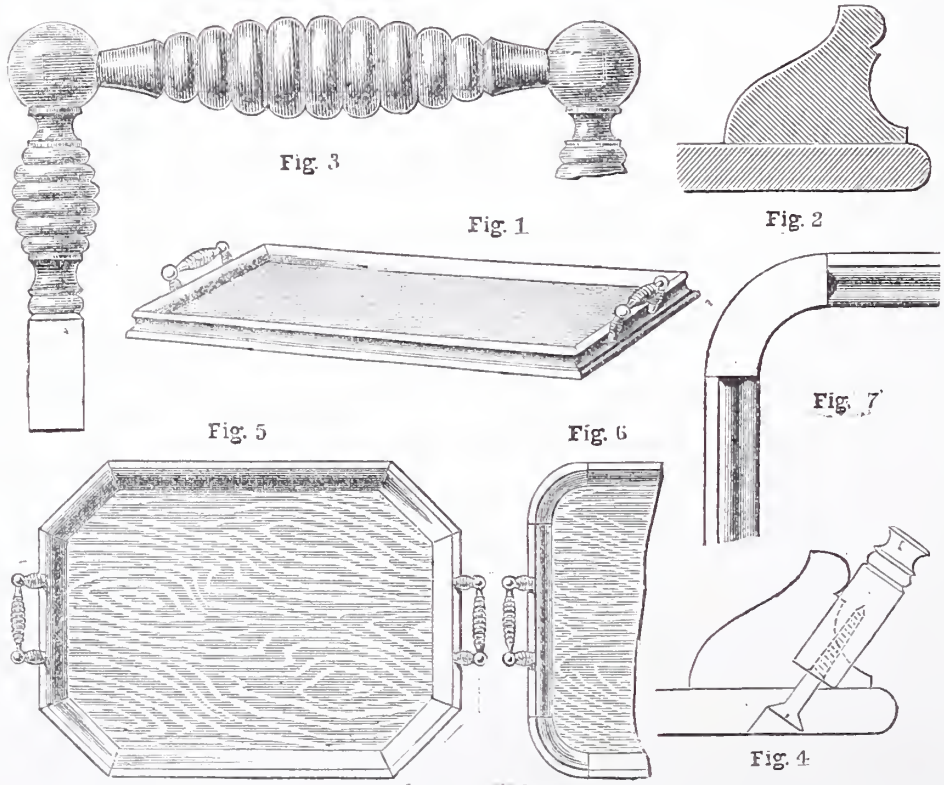


Fig. 1.—General View of Tray. Fig. 2.—Section of Rim. Fig. 3.—Handle (full size is 3¾ in.). Fig. 4.—Mode of securing Handle. Fig. 5.—Tray with Canted Corners. Fig. 6.—Tray with Rounded Corners. Fig. 7.—Block to form Corner.

The plain portions of the two uprights are set into the moulded rim a little bit, and then a screw is put into each from underneath and the handle is firmly secured. This must be carefully and strongly done, for it might be a serious matter if the handles gave way when some choice china was being carried in the tray. Then there would be lamentation! The illustration in Fig. 4 represents the method of securing the handle already mentioned, and if this be carefully executed there need be no fear. This completes the tray.

Another form is given in Fig. 5, with canted corners, otherwise it is exactly the same as that shown in Fig. 1. Yet another way of treating the corners is shown in Fig. 6, where they are rounded. These round corners may be turned in a circle, cut in four, and then placed in position; or a block may be cut to the shape and planted in the corner as shown in Fig. 7, the various members of the moulding being carved out after it is glued firm. Either way, the result is the same.

The size of the tray must be regulated to a great extent by individual taste; but a good useful dimension is 18 in. long by 14 in. wide for the size of the sole. Another size larger might be 21 in. long by 16½ in. wide; while a smaller size would be 15½ in. long by 11½ in. wide. Of course, any intermediate dimensions may be decided upon; but the reason for giving these particular sizes is that, while they are convenient by themselves, they also form a capital set of three.

In finishing such trays as these, the oak may be treated in different ways. It may be polished its natural colour or it may be stained a nice rich brown. Then, again, the sole may be light and the rim dark, the sole dark and the rim black, or the sole light and the rim black; this latter way has a very smart appearance indeed, and is the writer's favourite arrangement. The handles are always best to be dark, unless metal handles be substituted for wooden ones, in which case they should be electro plated.

## HOW TO IMPROVE THE APPEARANCE OF PLAIN CEILINGS.

BY T. R. BLACKETT.

In the majority of houses the ceiling presents a plain, flat expanse of white, without anything to relieve its monotony; sometimes a cornice is run round the room, which improves it a little, but in very few cases is anything done to improve the remaining portion of the ceiling. In the present article it is proposed to show how, by a very little extra expenditure, the appearance of the ceiling may be greatly improved.

In commencing to colour or whitewash a ceiling, it should first be washed with a brush and clean water, to remove all dirt, stains, etc., and, when dry, any rough places should be scraped or rubbed smooth, and all cracks filled up with plasterers' putty, or Paris white, mixed with a little plaster of Paris, to make it set. The cracks should be wetted with a brush, and the putty squeezed in with a small trowel, and rubbed down smooth. If the stains cannot be got off by washing, the ceiling should be painted white, in flat colour, or paint mixed with turpentine. Then commence to whitewash from one corner of the room, going over it as quickly as possible, and finishing with straight, even strokes, so as not to show any brush-marks. The strokes of the brush should be made towards the portion already whitewashed, so as not to show a join.

To mix the whitewash, break up the Paris white and put it into a bucket, putting as much water on as will cover it, and let it stand for a few hours; then pour off any clear water which may remain on the top, and mix it up with thin glue, or patent size which has been melted, in hot water. A little blue added to it will improve the appearance. After mixing it should stand for a few hours, when it will be ready for use.

After the ceiling is whitewashed, and dry, make a mark with a chalk line 6 in. from the cornice or walls, and get some narrow wall-paper bordering of suitable colour, and paste it on to the chalk lines, putting corner pieces at the angles; the bordering should be 1 in. or 1½ in. wide, and should be put on quite straight. If desired, the space between the bordering and the cornice may be tinted.

Or instead of using the bordering, colour a margin 6 in. wide all round the ceiling, and at a distance of 1 in. or 1½ in. from this, paint a line of chocolate ⅜ in. or ½ in. wide all round, and stencil an ornamental pattern at each angle. The edge of the coloured margin should be kept perfectly straight, and the chocolate lines should be painted to a rule, or straight-edge, held against the ceiling.

If there be a cornice, it should be washed, the cracks filled up, and whitewashed in the same manner as the ceiling, the cove, or large hollow, being tinted the same colour as the margin on the ceiling, but the other members of the cornice will look better white, as when tinted it gives the cornice a heavy appearance.

If the ceiling is large it may be divided into four panels, as shown in Fig. 1, the shaded part representing the colour. The width of the margins may also be increased in a large ceiling.

Fig. 2 shows another method of dividing a ceiling into panels, a circular margin being formed in the centre, round the chandelier.

Before laying the colour on it should be tried on some surface and allowed to dry, as if made too dark the ceiling will have a heavy appearance. Pink or salmon colour will be found very suitable colours for the margins, although others may be used: the stringing lines and stencilling will look best in chocolate, or similar dark colour.

Figs. 3 and 4 show two other forms of dividing the ceiling, which have a very good appearance. The centre portion of the panels may also be tinted, if desired, to a very light shade of the colour used in the margins; but when the room is low it is advisable to have the colours light, while for a lofty room, well lighted, a darker shade is sometimes an improvement. Each drawing represents one-fourth of the ceiling.

## A USEFUL DRILLING TOOL.

BY J. THOMPSON.

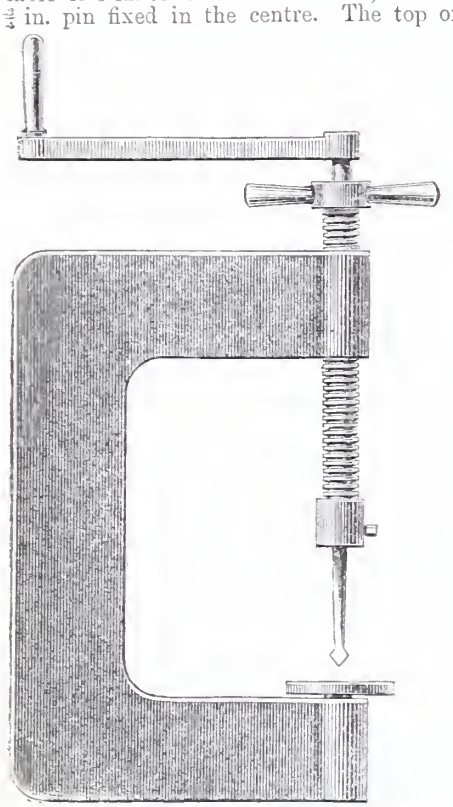
This drill, sometimes called a cramp drill, is a very useful tool, as it can be used in almost any position, and, by the addition of two lugs on the lower part of the frame, could be bolted to a bench. As it has not been described in this Magazine, a description of it may be interesting to some of the readers.

The tool is shown in the accompanying

illustration. It consists of a frame, with a screw fixed in the upper part; the drill spindle passes down the centre of this screw, having a projection on the lower end upon which the screw bears. The screw can be raised or lowered by means of a handle fixed on the top. A handle is fixed to the drill spindle for working the drill, pressure being given to it by the screw. A small table is fixed at the lower part of the frame, upon which the work rests while being drilled. The frame is made of wrought iron, 3 in. by ½ in., the ends being bossed for the screw and table. The hole for the screw is 1⅛ in. in diameter, tapped for the screw, and for the table ⅝ in. in diameter; they must be drilled in line with each other. The screw is a hollow tube of wrought iron or steel, with a handle fixed on the top.

The drill spindle is ⅝ in. in diameter, of steel, the lower end being made 1¼ in. in diameter, with a ½ in. hole drilled in it for the drills; it must fit the inside of the screw without any shake. The screw may be cut on the tube by a pair of stocks and dies, or in a screw-cutting lathe. In the latter case, it will be mounted on the spindle while cutting the screw, to keep it central. The top end of the spindle projects above the top of the tube, and has four flat faces filed upon it for the handle to fit on.

The handle is 10 in. or 12 in. long, fitted on the top end of the spindle, as shown. The table is 3 in. or 4 in. in diameter, with a ¾ in. pin fixed in the centre. The top of



A Useful Cramp Drill.

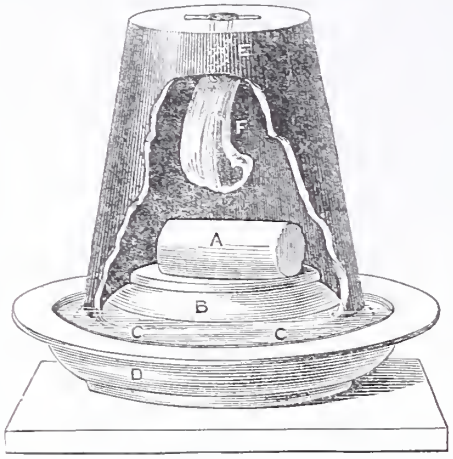
the table and the pin should be turned, so that any work fixed on the table will be drilled true and square. The shanks of the drills are turned, so that they run true, and a flat is filed on one side, by which they are fixed in the drill spindle with a set-screw.

No amateur wood-worker should be without some sort of drill to enable him to do such drilling in metal-work as he may be called on to execute in connection with wood-work. A metal-worker will be furnished with bigger and more powerful drills.

## A CHEAP BUTTER COOLER.

BY D. WILLIAMS.

Most housewives know how difficult it is to keep their butter firm during the hot weather, and how unpleasant it is to find the butter to be almost like oil. Well, here is a cooler which has these four advantages: (1) it costs practically nothing—a great consideration in these struggling days; (2) it is



A Cheap Butter Cooler—A, Roll of Butter; B, Saucer; C, Water; D, Dish; E, Hook for Meat; F, Piece of Meat.

perfectly equal to any refrigerator; (3) it is quite simple, and capable of being cleansed easily; (4) it is based upon sound scientific and hygienic principles. To make it, get an ordinary flower-pot (unglazed, of course), a saucer, and a glazed plate or dish. These are all that are necessary. Thoroughly clean the flower-pot inside and out, and dry it in a current of air, or the sun; then soak it well in clear cold water. Place the butter upon the inverted saucer; stand the saucer in the dish, which you must fill with cold water, taking care that the water is not high enough to reach over the top of the saucer; and then place the flower-pot over the saucer, and your cooler is made. It will keep your butter hard in the hottest weather: the hole at the top will allow free access of air, and the porous sides of the pot will hold the water, and yet permit the air to percolate through. This kind of cooler has been tried during a severe run of hot weather, and has been found to act beautifully. It can also be adapted for small joints of meat by bending a piece of wire as shown in the illustration, inserting the loop-part through the hole, and hooking the meat on inside. In this case the pot should stand upon two sticks, to allow the air to pass underneath. Flies will not readily go under the pot, and if the water be kept above the lower rim it will exclude them entirely; or a wire-gauze dish-cover could be placed over the whole. Still, as a meat-safe it is not so efficient as for a butter cooler; and, if it is once tested, there are few housewives who will again submit to the butter going oily or turning rancid. The accompanying sketch will show how the article is made. One thing to be remembered is: do not let either the inside or outside of the flower-pot get greasy or dirty. The oftener it is scrubbed, the better will it act. Grease or dirt prevents the water soaking into it, and the cooling properties become impaired.

The utility of a cooler of this kind will be far more apparent when one has been made and brought into use.

## OUR GUIDE TO GOOD THINGS.

**** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 119.—"The Optics of Photography and Photographic Lenses."

The book that bears this title is published by Messrs. Whittaker & Co., London, and is written by Mr. J. Traill Taylor, editor of the "British Journal of Photography." It forms one of the series known as Whittaker's Library of Arts, Sciences, Manufactures, and Industries, and, as the author takes care to explain in the preface to his work, "is not theoretical but practical, and it is not intended for the makers, but the users, of photographic lenses." He further explains that, although there are many lenses in the market which are not even mentioned by name in the volume, inasmuch as the chief difference in them is to be found in the variations of diameters, foci, and curves of the lenses, and their distinction by special trade terms, he has wisely preferred in all cases to deal with the lenses in classes associated with the name of the first inventor of each particular kind. The book is well conceived, and written in the clearest terms, and cannot fail to be useful to every photographer who desires to thoroughly understand his business and to comprehend the nature of the instruments and appliances he uses.

### 120.—"The Practical Telephone Handbook."

This is another volume of the series mentioned above, and is issued by the same enterprising publishing firm. It is written by Mr. Joseph Poole, Chief Electrician to the late Lancashire and Cheshire Telephonic Exchange Company, Manchester, and a Whitworth Scholar of 1875. Although, considering the importance of the subject, the manual itself is of moderate size and cost, yet it is thoroughly practical, and gives in detail, as far as the space will admit, the most recent methods of telephonic working. It is not only a volume suited to meet all the requirements of telephone *employés*, but one which affords all the information necessary to users of the telephone and to all who desire to acquire some knowledge of the nature of the instrument and its construction and use. The text is elucidated by nearly two hundred and thirty diagrams and illustrations.

### 121.—Quarterly Supplement to the "Wood Carver."

This is not the *Wood Carver* noticed in page 474 of this volume, but a work from the pen and pencil of Mr. J. S. Gibson, of Edinburgh, and published by Messrs. Scott & Ferguson and Menzies & Co., of that city, and Messrs. Simpkin Marshall & Co., of London. It contains thirty-four full-sized designs of useful articles, with practical instructions in carving, modelling, etc. The Supplement to this desirable work—which should be in the hands of all wood carvers—is issued quarterly. The one before me contains bold and well-executed designs for panels for a lamp-stand, the back and seat of a spinner's chair, a photo frame, and a brief paper on "The Study of Historic Ornament," with two appropriate illustrations.

### 122.—Melhuish's Illustrated Price List of Cabinets.

Amateurs who are desirous of obtaining a handsome tool cabinet with work bench and other accessories in combination should not fail to send for Messrs. R. Melhuish & Sons' new catalogue before purchasing. Space unfortunately prevents me from making more than this very brief mention of Mr. Melhuish's specialities in this line. The Editor.

*Notice as to New and Important Features to appear in*

"WORK."

SUCCESSFUL as "WORK" has been during the three years which have elapsed since the First Number was issued, the

NEW AND VERY IMPORTANT PAPERS

which will appear in the next and forthcoming Numbers will, it is believed, still further extend the circle of its readers and the sphere of its usefulness.

Amongst the Special Series of Contributions for which the Editor has already arranged, and which will be in addition to the usual variety of papers, may be mentioned :—

**Original Designs in Art and Ornament for all Art Workers.**
**Induction Coils and Electric Work in General.**
**Bent Iron Work—Affording an Occupation for Women.**
**Staircasing and Handrailing—for Professional Workers.**
**Chemistry Appliances, and How to Make Them.**
**Designs and Studies in Home Decoration.**
**How to Learn "Drawing Office Work."**
**Furniture—Original Designs in.**
**Photographic Appliances, and How to Make Them.**
**Coach and Carriage Painting.**
**Microscopic Appliances, and How to Make Them.**
**Stories of Great Engineering Triumphs.**
**Pages of Easy Carpentry.**
**The Spectroscope: How to Make and Work It.**
**Tools: How to Buy, Select, and Handle Them.**
**Practical Papers on** :—How to Whitewash a Ceiling.—How to Purify the Cistern.—How to Control the Gas Meter.—How to Put on a Lock.—How to Mend a Window, etc.
**How to Grind Optic Lenses.**
**How to Learn to Design.** By a Member of the Arts and Crafts Guild.
**Sewing Machines: How to Select and Work Them.**
**Poker Work, and How to Do It.** By a Danish Art Teacher.
**Telescope Making and Working.** By a Practical Hand.
**Country Carpentry**: Being a Series of Papers on Profitable Outhouse Building.
**Workshop Joinery in all its Stages.**
**Slaters' Work.** By a Master Slater.
**Plasterers' Work.** By a Working Plasterer.
**Jewellers' and Silversmiths' Case Making**
**Stained Glass Window Making—Domestic and Ecclesiastical.** By a Foreman Worker.
**Work and Power Papers.** By a Civil Engineer.
**Design and Decoration of all Ages** :—1. Barbaric Art.—2. Greek.—3. Celtic.—4. Early English.—5. Chinese.—6. Japanese.—7. Indian.—8. Naturalistic.—9. Conventional.—10 Grotesque.—11. Ecclesiastic.—12. Application of Styles.
**Embroidery: Its Principles, Purposes, and Practical Application.**
**Simple Arts for the Cottage.**
**How to Make an American Organ.** By a London Factory Foreman.

A notable feature of the New Volume will be the weekly publication of

TRADE AND LABOUR NOTES, AND NEWS

from the principal trade and industrial centres. The Editor has secured the co-operation of leading men holding responsible official positions, whose notes will thus possess a peculiar value, and be of special importance to all workers.

Arrangements have also been made by which the Editor hopes to secure from time to time direct intelligence from Colonial districts offering fields and opportunities for emigrants and workers who suffer from the overstocked condition of the home labour market.

There will also be a separate column devoted to a

WEEKLY SURVEY OF SCIENCE,

in which the latest developments of practical science will be chronicled in a concise and readable manner.

Thus it will be seen that "WORK" will even more fully than heretofore carry out its aim of furnishing clear practical exposition, as well as Designs and Illustrations, of

EVERY ART, CRAFT, AND SCIENCE

that bears directly or indirectly on handiwork of a constructive or decorative character, and at the same time serve as an index to the worker upon questions and matters connected with labour and the labour market—the fluctuations in which so immediately affect him, and in which he must necessarily feel an active interest.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London; and all Booksellers'.*

## SHOP:

### A CORNER FOR THOSE WHO WANT TO TALK IT.

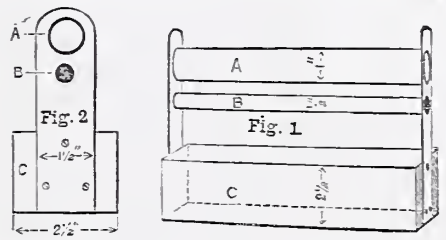
*** In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given.*

### I.—LETTERS FROM CORRESPONDENTS.

**Plain Sketches.**—THEO D'OLITE writes to T. P. (*Frodsham Bridge*) (see p. 717, No. 149) :—"C. E. is, I think, incorrect in supposing that Maxton's very complete work on Engineering Drawing is to be found in Spon's catalogue. My copy is one of the Weale Rudimentary Series published by Crosby Lockwood & Co. I should advise T. P. to get it by all means; he will never regret the expenditure of 4s. 6d. less."

**Violin Making and Varnish.**—H. H. (*Latchford*) writes :—"Having found a difficulty in bending the ribs of a viola so that they would retain their shape on the mould, I set about making a 'bender;' and as it is a great success, I send you a rough sketch of it for 'Shop.' It is heated by placing a piece of round iron bar red-hot into the tube. For convenience' sake I have put a wooden handle on the heater. The ribs are passed between the bar and the tube, and bent over the latter. A thin wedge of hard wood is useful for clipping the ribs to the tube where necessary, but the bar is intended to act as a grip. I have just bent some 'cello ribs out from maple, and they retained their shape splendidly. As anything that saves time and patience is worth knowing, I send you the sketch without further remarks. The articles which recently appeared in WORK on Violin Making, though in themselves the best of the kind ever written, left the matter of varnishing in a very vague state. I suppose this is through violin-makers guarding their trade secrets very closely. There has been a great deal of nonsense written about the old makers' so-called amber varnish. My

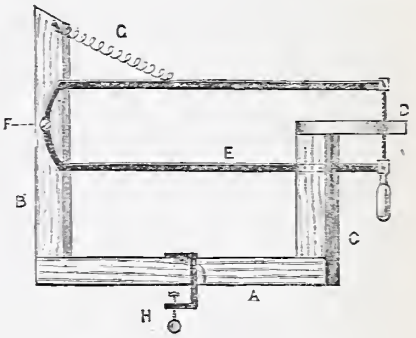


Violin Bender. Fig. 1.—A, 1 in. Iron Tube, either turned or smooth; B, ½ in. Round Iron Bar; C, 2½ in. Wood Block. Fig. 2.—Section—A, 1 in. Tube; B, Bar.

own opinion is that the old varnish was a very simple affair—how could it be otherwise, seeing the outlandish places these people lived in? With this view I have recently been experimenting in varnishes, and have succeeded in getting one which I think will satisfy anyone. I cannot give you the exact quantities, but I will tell you how I made it. I procured 2 oz. juniper gum, ½ oz. elemi, ½ oz. myrrh, ½ oz. benzoin. These I dissolved separately in methylated spirit previously coloured (just sufficient spirit to dissolve the gum). For colouring I used: yellow, gamboge; red, alkanet root, or dragon's-blood; brown, aloes. When thoroughly dissolved, I mixed the gums with about 3 oz. linseed oil (boiled), added 1 oz. turps, and boiled altogether in a water bath until a great proportion of the spirit had evaporated. This I poured into a bottle when cold, and the result was a sort of jelly. I added about a tablespoonful more spirit, and shook the lot up, and in a day or two the jelly broke up, and a beautiful clear varnish rose to the surface, whilst the undissolved gums and oil remained at the bottom. I poured off the clear varnish, and put a little spirit in what was left, gave it another shaking, and did as before. This process I repeated till there was nothing left but the excess of oil and the foreign substances and dirt which are in all gums. This varnish takes about twenty-four hours to set, and it should be strained through fine muslin before use. It requires about six coats to varnish a violin. The violin should be oiled in before commencing, and each coat should be rubbed down with oiled felt. It is better for keeping a month or two; and although anyone who tries it may fail in the first attempt, yet it is well worth any trouble you may have. A mixture of brown and red makes a very nice colour. The yellow is rather light for some tastes, although I consider the viola I varnished that colour looks very well."

**Needed Inventions.**—B. A. B. (*Hampstead*) writes :—"There is a need for a sash pulley that can be easily oiled, or else composed of such metals as require no oiling. It should be similar in appearance and dimensions to those now in use, so that the old ones may be easily replaced by a better pattern. A pulley suitable for the balancing of side lights of bay windows, where there is no room for sash weights, would sell. The only disadvantage of such a mode of hanging sashes is that when the lower sash is raised the upper one descends; but that is better than both being fixed, as they are generally made at present."—[Thanks for these notes for needed inventions and requirements. We wish you and every reader of WORK would begin and continue to favour us with any necessity of this kind as it comes before you, whether in practical work or idea only, in order that prominence might be given to such useful suggestions in WORK. —ED.]

**Fret-saw Contrivance.**—W. S. (*Cambridge*) writes :—"I send a rough sketch of a hand fret-saw contrivance. Two great advantages of it are: it cuts the work true, like a treadle machine; also, it leaves the hands more at liberty to thread the saw through the work, and costs but a few pence—that is, if you have the saw-frame by you. Of course, you can buy these made in first-class style, but they then come to 6s. or 7s.; mine cost me only 2d. for spring and screws, as I had frame and cramp by me, and wood from an old soap-box. Let me say it



Hand Fret-saw Contrivance.

is all made of wood, screwed together, and those handy with their tools can dovetail the uprights into the base-board. A is the base-board, 4 in. wide (or about) and 1 in. thick; B the upright to which the saw-frame is screwed with a small round-headed screw, with just enough play to work the saw up and down easily; C, upright to which the table, D, is attached. Run the saw down C for the lower half of the steel frame to work in, which also acts as a guide for the frame; screw table on top of C, and bore a small hole through table, D, just where the saw must go through. G is a spring from the frame to the uprights; H, cramp by which to clamp the base-board to the table or bench. All the wood would be best 1 in. thick except the table, which may be ½ in. hard wood, either round or square, but must be smooth on top to move the work easily when sawing. It will be seen that two small holes will have to be bored in the saw-frame, E, one for screw in centre of back, and the other for the spring in the top part of frame. The length of base-board and uprights depends on the length and width of saw-frame."

**Etching on Tools.**—LOST MOTION writes :—"I have noticed several recipes for etching names on steel tools in your 'Shop' columns, and can from personal experience confidently recommend blue vitriol, or sulphate of copper, and common salt. After coating the blade with wax, and scratching in the name with a needle or some other fine-pointed article, sprinkle over the scratched place some finely-powdered sulphate of copper, and cover this with common table salt; leave for twelve hours, at the end of which time the name will be found *deeply* bitten in."

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Camera Lens.**—SUNMAN.—The explanation of the two brass tubes is this: The brass tube to which is attached a flange is intended to be screwed into the camera to hold the other brass tubes in which the lenses are fixed. Each pair of lenses, forming combinations of different focal length, can thus be easily adjusted for working. If only one combination is wanted, it can be fixed in the single tube with the flange, two tubes being unnecessary. Any camera will suit these lenses, providing they will draw out sufficiently far to focus.—D.

Camera Lens —A, Outside Tube; B, Flange; C, Inner Tube; D, Stop; E, Lens.

**Honeycombed Holes.**—C. T. (*Bradford*).—Put a bit of soap, about the size of a five-shilling piece, into the metal just before pouring; stir it round for a few seconds, and pour slowly, without splashing, from one end of the ingot mould. Nothing more is needed to ensure sound ingots.—J.

**Model Loco' Boiler.**—E. W. L. (*Newcastle-on-Tyne*).—You can do nothing with it except throw it on the scrap heap. It is too small for charcoal, and is not rightly made for a spirit-lamp. Have nothing to do with these trashy bought engines. If

you want a *working* model, you must either pay a good price or spend a lot of your own labour in constructing one. Cheap engines of this type are simply useless.—J.

**Cork Picture-Frames.**—W. R. W. (*Colne*).—I imagine this to be too trivial an art to have any book specially devoted to it—at least, I know of none. Within the narrow limits of the "Shop" columns, any designs which I could give would be too small to be of practical use; but our Editor promises the space, and I will give what you require as soon as possible in a short illustrated article.—A. Y

**Magnetism.**—H. A. B. (*Middlesbro'*).—(1) When a piece of iron is placed in contact with one leg only of a horse-shoe magnet, some of the lines of force are lost in air, since they spread around the edges of the steel bar and are not concentrated in the iron armature. When, however, the soft iron armature is placed in contact with both legs, some of the lines between the poles are also taken up, and, as a consequence, the hold is more than double that of one pole only. The relative difference may be ascertained by boring a hole in the armature and suspending from it a small scale pan, then adding small weights until the attractive force of the magnet is overcome by the added weights. (2) I have no data at hand to guide me in answering your second question. As the coercive force of magnetised steel is high, it will not be much affected by the earth's magnetism. At the same time, reasoning from theory, one would suppose that the magnet with its south pole pointing downwards would be weakened, and the other slightly strengthened. What is your experience?—G. E. B.

**Battery for Electro-Motor.**—R. McG. (*Govan*).—As the working resistance of the electro-motor is low, you must employ a battery giving a large volume of current with a low internal resistance of the cells. Batteries suitable to this work, having a low internal resistance, are the Bunsen, the Grove, and modifications of these for use with chromic acid. Get a set of four Bunsen cells, taking a quart of liquid to charge each cell, and charge the porous cells with a mixture of chromic acid, 3 oz., chlorate of potash, ½ oz. in each pint of water, made acid with 3 oz. of sulphuric acid. Charge the outer cells containing the zinc cylinders with a mixture of one half-pint of sulphuric acid to each ten half-pints of water. In Nos. 1 and 2 of WORK you will find a full description of the Bunsen battery. These numbers will cost you 3d. by post. If you have the back numbers containing the articles on "Model Electric Lights," you will find some suitable batteries for your motor described in the third article in WORK, No. 89.—G. E. B.

**Zither.**—S. S. (*London, W.*).—An article on the Zither appeared in No. 129, and "Hints on the Stringing of the Zither" in No. 139.

**Magnetic Needle for Telegraph Instrument.**—TELEGRAPH.—A telegraph instrument of the single needle type has two needles: one on the outside of the dial to act as a hand or pointer, and one inside the instrument, behind the dial. Both are fastened to the same spindle, and therefore both move together. The outside needle need not be magnetised, but the inside needle must be of hard magnetised steel. This is, I presume, the "small plate in the back" mentioned in your letter. It works inside a coil of very long fine wire, much the same as in a galvanometer. A paper showing how to construct a galvanometer is in the Editor's hands; and as the coils and needles of both instruments are the same, you will do well to follow the instructions given in that article. The lozenge-shaped piece of steel to go inside the coil may be magnetised by drawing its ends several times over the ends of a permanent magnet, such as a horse-shoe magnet, or winding it with a coil of silk-covered wire, and sending an interrupted current from a strong battery through the coil.—G. E. B.

**Cutlery Case Making.**—J. S. (*Amsterdam*).—There are two ways in which the "puffing," as it is called, is carried out. The formal way you refer to is done by machine, and the best work we know of carried out in that manner is by Messrs. Dewsnap, cutlers' case maker, Sheffield. The other form of puffing, which is irregular in appearance, and, to our mind, the most effective, is done by hand in the following way: Cut to the size required a sheet of paper—the sort usually employed in the trade is called "ledger" paper, and is, in fact, procured from old account books of good quality; place on this a layer of wadding, and then cut the satin about one-third larger than the "cushion," as the combined paper and wadding is technically named. The satin is then glued all round on back edge of cushion in small pleats equally distanced. When the glue has dried, the satin is arranged in puffs, as small or as large as taste or the size of the cushion may dictate, and these puffs are fixed or kept in position by lightly sewing right through the wadding and paper with needle and silk thread matching the satin. The machine for corrugating or ribbing pasteboard is made by the employment of two steel rollers with fluted surface all round, held in a framework precisely as the ordinary wringing machine used in laundry work. The rollers are adjusted so that they cog into each other when the handle of machine is turned, the space between the rollers being regulated by a screw. But the corrugated pasteboard itself is quite an ordinary article in the market, and can be obtained so cheaply that, unless the pleasure lies in the constructing of the machine, it seems hardly worth while going to the expense of making the machine to produce it. This corrugated board is largely used by wine merchants for bottle packing, by silversmiths' case makers, and others, and can be obtained from Messrs. Munt & Son, Cross Street, Hatton Garden.—P.

**Lens.**—W. R. R. (*Carlisle*).—There is no better all-round lens than a good rapid rectilinear of 8 in. focus. By removing one of the combinations from the mount, the remaining one makes an excellent landscape lens, providing the camera will rack out sufficiently. The exposure will, of course, be longer in proportion to the extra length of focus. If half second is required with the complete lens, two seconds will be necessary for the half of it. *Any* of the numerous photographic dealers will supply your requirements. We can scarcely recommend one before another. All dealers charge about the same for the same quality of goods, unless a speciality is made of any particular class. The weekly periodicals and WORK teem with advertisements.—D.

**Gold Colouring and Suitable Alloys.**—R. C. (*Battersea, S.W.*).—In the first place, the best book for practical information is G. E. Gee's "Goldsmiths' Handbook," published at 3s. by Crosby Lockwood & Co. This deals at much greater length than I can with the alloys, colouring mixtures, etc. Get it by all means; there are many useful tips in it. Now for the special difficulties that you write about, the chief one being the different surface you get over the soldering seams to what you have over all the rest of the article. Your colouring mixture is all right, except that there might be a little more acid in it; the fault lays undoubtedly in the solder. In both the hard and the easy solder there is too much silver. ·010 should be plenty of silver to add to ·250 of 15 carat for the harder quality, and ·090 for the easy. If you calculate it out, you will find, I think, that your easy solder is less than 12 carat, and 12 carat is the lowest quality which should be coloured with the mixture you give. In our workshop there is added to the easy solder some metal like zinc. Now the use of zinc in an alloy causes it to melt at a lower temperature than the quality would if alloyed with silver and copper only, therefore a slightly higher quality of gold can be used for soldering than would otherwise be the case. You might get the book, and try Gee's recipes; but meanwhile, instead of your last alloy, try what a mixture made up of these proportions will do: 15 carat, ·250; silver, ·075; pure zinc, ·01. This is very much like what we use for a differently composed 15 carat to yours. The zinc must be added when the other metals are perfectly melted and ready to pour; and do not spare the borax. As to getting a paler colour on your work, surely this can be got by adding more water to the colour than you have done in the last stages. Write again if this does not clear matters up.—H. S. G.

**Bronze and Gold Lines on Picture Mounts.**—R. H. (*Lancaster*).—There are different ways of producing these lines. Were the work of a cheap character, I should mix bronze powder with varnish (the clearer the varnish the better), and thin with turps till the mixture would flow freely from a how-pen or lining pencil. Work thus done will *not* be bordered by a greasy line. Pale gold-size may be used instead of varnish; the bronze will then be darker, but will not necessarily look amiss. A higher class of work may be made by first drawing the lines in isinglass or other water-size upon this, when dry, drawing the lines again in gold-size, and when the gold-size is just tacky, rubbing bronze powder over it. If real gold-leaf is used, it must be applied by this last process; but if the mount is porous, as mounts often are, more than one coat of water-size may be necessary, since gold-leaf does not adhere so readily as bronze powder. A water-size may also be made strong enough to fix the bronze or gold alone. When similar lines have to be repeated many times, as in photographic albums, the printer will do the work more cheaply than it can be done by hand.—S. W.

**Type-Writing by Lithography.**—L. J. K. (*Dublin*).—(1) "Can any sort of ink and paper be used with a type-writer, so that the type-written matter can be transferred to a stone to have a large number of copies produced by lithography; and if so, of what kind?" We are not aware that type-writing has been so applied, but we know of no reason why the plan should not be feasible. The ink, we presume, would have to be the ordinary lithographic transfer writing ink, for no other will adhere to stone, and the paper the ordinary litho transfer writing-paper, both of which our correspondent may get from Hughes & Kimber, Fetter Lane, E.C., or any other dealer in litho materials. We assume that his plan will be to rub down his stick of ink (which will cost him 1s.) to the thickness required, and in it to soak a ribbon or band similar to ordinary type-writing bands. It would be desirable that the face of the paper should *not* be handled, as any marked or soiled portions will readily roll up when transferred to the stone. It would also be desirable that the matter should be put upon the stone as soon after it is written as possible. These are the best suggestions we can give him, but he must bear in mind that they are suggestions merely, and that we cannot promise that they will lead to success. (2) "Is there any other surface—parchment, zinc, tin-plate, etc.—to which the copy could be transferred?" We presume not, unless the surface can be charged with some kind of composition for the transfer to adhere to. He does not say for what purpose he wishes to transfer to these surfaces. Are we to suppose that it is for the purpose of multiplication by lithography? If so, his chances of transferring successfully to a litho zinc plate will be much the same as to stone, and our suggestions given in reply to his first query will be equally applicable here. He can get a zinc plate, of any size, from the Litho Zinc Plate Co., Ltd., Hull. (3) "Is it feasible for an amateur to reproduce the copies, or must it be done by a lithographic printer?" We fear that it would not be feasible, unless the amateur were skilled in lithography.—S. W.

**Stereoscope.**—G. P. D. (*Aberdeen*).—Stereoscopes were mentioned on p. 521, Vol. II., of WORK, and on p. 541, Vol. I. I rather fancy that I have seen something concerning them in Vol. III.; therefore, when the index appears, I should advise you to search it.—J. S.

**Kallitype.**—J. A. (*No Address*).—No; the kallitype process is a rapid process, and the image produced by development, which would render it difficult to work for the purpose mentioned. It would produce white lines on a black ground. The thickness of the paper would interfere with this print being used as a negative, although it might be so used to produce black lines on a white ground. The paper may be had from Fallowfield, Charing Cross Road, London, W.C. We are now able to see how, without measuring, any definite quantity of saturated solution could be ascertained. The difficulty with all saturated solutions is to ensure that the *same* quantity of substance is contained in a given measurement, as the saturation *varies* with the temperature. In all exact measurements, so-called saturated solutions are never used unless the saturation at a *certain temperature* is stated.—D.

**China Drilling.**—TRYER.—The article upon "China and Glass Riveting" appeared in Vol. II., No. 53, p. 4. As regards the second part of your query, although you can get drills in London, I would advise you, in your case, to write to Mr. E. Claxton, Tower Street, King's Lynn, and he will make you just what you require. He is a practical man, and knows exactly what is wanted for the work. Explain that you have the spindle, and only need a diamond drill, and also mention if it is needed for light or heavy work.—W. E. D., JR.

**Letters for Signs, etc.**—H. H. (*Brighton*).—I think you will find Willing's Patent Enamelled Copper Letters as good as anything you can use, as they can be affixed to glass with ease, and look exceedingly well. They are also suitable for facias, signs, or anything of that kind. I have no doubt you could get appointed agent, and you could affix them yourself, as the firm supplies cement for the purpose, accompanied by printed instructions for use. Apply to Mr. J. Willing, Clerkenwell Green, London, E.C., enclosing business card and asking terms. As regards rubber stamps, not much is to be made out of them now, as so many are agents; but if you think you could do a little business in them, write to some firm for their terms. There are plenty of manufacturers to choose from. I could not undertake to say which is the best firm; but if you do not know of any, here are two or three addresses: Crystal Palace Marking Ink Co., 75, Southgate Road, London, N. (see advertisement in WORK); Ireton & Co., Gracechurch Street, London, E.C.; J. Berkley, Livery Street, Birmingham.—W. E. D., JR.

**Cement.**—CONSTANT READER (*Ottawa*).—One of the easiest cements to make is to dissolve isinglass in acetic acid by the aid of heat (a water bath—glue-pot—for instance), and it will join all the articles you name, but it won't stand water or damp. Pound the isinglass before adding the acid, and if it needs it, strain through a piece of muslin. Keep in a well-corked bottle. Or perhaps the following might suit you better. It is a little more trouble to make, but I believe it is a thoroughly reliable cement: Dissolve five or six pieces of gum mastic, the size of a large pea, in as much spirits of wine as will suffice to render it liquid. In a separate vessel dissolve as much isinglass (previously softened in water, though none of the water must be used) in rum or other spirit as will make a 2 oz. phial of very strong glue, adding two small pieces of gum ammoniacum, which must be rubbed or ground until they are dissolved. Then mix the whole together with a sufficient heat. Keep it in a closely-stopped bottle, and, when it is to be used, set the bottle in boiling water. You do not say if you need the cement in large quantities; if you do, you can easily increase each item. Strictly weighed articles are not needed, but simply a general adherence to the formula.—W. E. D., JR.

**Hive Appliances.**—G. S. T. (*Birmingham*).—(1) It would scarcely be right for me to name any particular dealer as being the *best*, but most of the large manufacturers are sure to have agents in Birmingham. If you write to Messrs. Abbott, Southall, London; Messrs. Blow, Welwyn, Herts; Messrs. Baldwin, Bromley, Kent; Messrs. Neighbour, of High Holborn, London, and ask for a catalogue and the name of their agent in your town, the information will more than repay you for your trouble. It is a pity hive-makers do not advertise more in such a paper as WORK. Many amateurs would, I am sure, become their customers for such things as they do not care to make for themselves. (2) The zinc you name would cost about 1s. 6d. (3) Cowan's "Guide-Book," at 1s. 6d., to be got from any of the dealers or booksellers, is as good as any.—APIS.

**Distillation.**—STILL.—Plenty has been written upon this subject, but I am unable specially to recommend any treatise for your purpose. The process is so simple that probably an encyclopædia

article would give all the information you want. You ask whether you can use your still for making perfumes. Certainly, but you must remember that only the coarser perfumes, such as those from orange and lemon peel, geranium leaves, etc., are made by distillation. The more delicate ones, such as those from violets, jasmine, etc., are extracted by grease, either by packing the flowers in lard (the process known as *enfleurage*), or in the *bain Marie;* the perfume being afterwards drawn from the grease by alcohol. Be careful how you use your still, or you will have the Excise authorities down upon you.—M. M.

**Electric Bells.**—W. H. C. (*London, S.E.*).—Articles on "Electric Bells" appeared in Nos. 12, 18, and 20 of WORK.

**Caning Chairs.**—A. H. P. (*Lewisham*).—I will take your questions *seriatim*. (1) Cane can be bought, ready for use, in Bethnal Green Road, at one or two shops close to the junction of the old and new parts of the road. A short sharp knife, a punch (often made of a stout broken bradawl), and a light hammer are the only tools required. Punch out old pegs from below. Cane can be split and made uniform by passing it under a sharp razor blade fixed at the proper distance from the block which forms the base of the tool. (2) I have seen caning done, and the two strips across and two strips along were done before the diagonals were put in. (3 and 4) The caning was done throughout before the pegs were put in, but the cane was drawn fairly tight, one strip of cane being laced through and brought back as many times as length will allow. (5) The wooden 3-ply seats are cheaper than cane seats, if you have to put out the caning. You can certainly fix the 3-ply seats yourself. The only other plan is to have a stuffed seat. (6) There are three different modes of caning, or rather, three prices: one with canes described as above, six rows in all, with a row as bead held down with cane staples—3d. and upwards is charged for this; secondly, the same without the bead; thirdly, a cheap plan adopted by the people who cane chairs in the street, who only use four rows, and often use the inner strips of cane for two of the rows: these having no smooth surface, get dirty and rough very soon.—B. A. B.

**Cement.**—KILN.—For filling up cracks in earthenware, I know of nothing better than plaster of Paris mixed with water. If mixed with alum water, it gets very hard indeed. This, perhaps, may answer your purpose better than with simple water, although the latter way is that which professional china-menders use.—W. E. D., JR.

**Incubator.**—INCUBATOR.—You can obtain glass tube and all other fittings from Mr. T. Stevens (see advertisement in "Sale and Exchange" column of WORK).—LEGHORN.

**French Polishing.**—W. B. (*Rushden*).—It is impossible to instruct you in the whole art of polishing in the limits of a "Shop" reply, but as you are a new subscriber, I will give you the outline of the *modus operandi*, as practised by myself. I cannot advise you to attempt a chest of drawers for a beginning, as probably you would only make a mess of it. Try your hand on some waste pieces or a smaller article; then, when practice begets confidence, tackle the larger job. If you can get to see a polisher at work, it will give you some insight into the method of using the rubbers. Your work being all smoothed and ready, it will first be necessary to fill up the pores of the wood. For this filling take a sufficient quantity of tallow, and work it well up with powdered whiting to form a stiff paste. Colour to match the wood (for mahogany I use portions of dry ochre, umber, and Venetian red); moisten, if necessary, with a little raw linseed oil, and with a piece of rag apply it all over the surface of the work across the grain, so as to fill all the pores. Now remove the surplus, and we are ready for polishing. If you wish to darken the wood, apply a weak solution of bichromate of potash before "filling." I, however, much prefer mahogany unstained. Now get some French polish (buy it at your nearest oil and colour shop), raw linseed oil, methylated spirit, wadding, a piece or two of flannel, and a supply of clean white rag. Take some wadding sufficient to make a ball about 2 in. in diameter (this is a convenient size, but it must be determined by the work in hand), cover this with a piece of flannel, and saturate the pad with polish. Now take a piece of rag, and enclose the pad in it, gathering the corners all together tightly, so as to present a circular surface to the work. When ready, pass the rubber over the work in light circular strokes, beginning at one end, and gradually traversing the whole of the surface to be polished, letting each stroke overlap the last. Moisten the rubber with fresh polish as the former lot gets used up, and continue the rubbing until your work presents a fairly even polish, increasing the pressure on the rubber as the work proceeds, and moistening the surface of the rubber with a trace of linseed oil if it shows any signs of sticking. Now put the work aside for an hour or two, to allow the polish to harden, and upon resuming, give it a rub with fine glass-paper to remove all inequalities, and proceed with a second coat of polish. When there appears a nice even coating, lay aside again to allow it to harden, and, if possible, leave it till next day, when you may proceed to "spirit off" the work—that is, to work out the oil so as to leave a clear bright surface. Make a rubber as before, and moisten with methylated spirit only, and go over the work in the direction of the grain with light quick strokes, until all cloudiness disappears. Spiriting off is the most difficult part of the job, as, if unskilfully done, the polish is apt to tear up in patches. Remember that practice makes perfect, and if at first you don't succeed, try again. I omitted to mention that all polishing operations must be performed in a warm room.—H. E.

**Painting Slides.**—BUSY BEE.—(1) "Is it within the power of an amateur to paint optical slides?" It depends on the ability of the amateur. Anyone with a fair knowledge of drawing, an eye for colour, and patience, could, I am sure, with practice produce really good results, and in time might even secure professional work. (2) "What kind of paint is used, and where procurable? What kind of brushes are best, etc.?" The paints used are those known as transparent, and can be bought of any dealer in artists' material. As BUSY BEE lives in London, many names will be familiar to him—such as Newton, Reeves, etc. The colours may be procured either as water or oil; BUSY BEE must decide for himself which he will elect to work with. I can only say here that the treatment of the work in each kind is different. The colours used are as follows: *Yellows:* gamboge, yellow lake, Italian pink, yellow madder. *Blues:* Chinese, Prussian, indigo. *Green:* verdigris. *Reds:* crimson lake, pure orange, burnt sienna. *Browns:* Vandyke, madder brown. These can be procured at about 4d. per tube; madder lake, French ultramarine, and pure scarlet at 1s. per tube. Besides paints, varnishes will be required—viz., copal and mastic—also gold-size and turps. Mastic 3 parts, and turps 1, are mixed with gentle heat with lampblack for outlines; mastic, ¾ oz., turps one teaspoonful, and 20 drops of gold-size to mix the colours. Brushes.—These must be sable, varying from 0 to 6, and one or two riggers made, I think, of ox-hair for outlining. In addition to these materials, an easel will be required of a skeleton kind, so that the slide shall simply be gripped and allow a piece of white paper to be seen through the slide. This will enable one to see how the colours are spreading. (3) The glass does not require any preparation beyond rendering it perfectly clean. The glass painting referred to in Vol. I. is for window decoration, and not for optical lanterns. When BUSY BEE comes to work, he will find difficulties which as yet he does not anticipate, but which, by patience, may be overcome. Look out for coming articles in WORK.—O. B.

**Repairing Cycle Tires.**—J. B. (*Eastbourne*).—I have to say that, in my reply to RETRENCHMENT (see p. 652, Vol. III.) anent pneumatic tires, if I remember rightly, the reference was to the "Dunlop" species of pneumatic tire. In that reply I adhered to a rule I have ever endeavoured to observe—namely, never to attempt giving information to others from theory, but only from my own personal experience. I had not, neither have I yet, any personal experience of the construction or repair of the "Dunlop" tire. I have "Points for Cyclists." I could easily have copied out what it has to say regarding tire repairing and sent it as *my* reply. I did not do so; first, because I had no practical knowledge of the process, and secondly, I do not consider the instructions there given sufficiently minute to guide anyone without other aid in the mystery of repairing these tires. There was an air of mystery surrounding the repair of these tires that does not now exist. The difficulty of repairing them still exists, however, and the necessity also; for the tire is admittedly even yet not perfect, and I think the art of repairing them is not worth the candle. I do not believe the tire has come to stay, and I do not care to spend time learning the mystery of repairing them, which at best is not a simple, but a ticklish job. I have also a book issued by the Pneumatic Tire and Booth's Cycle Agency. The instructions therein given are much more precise than in "Points for Cyclists," yet at the outset the latter book says: "If the rider has previously got a lesson in repairing, he will easily follow these instructions. If not, he must make sure that he understands the *construction* of the tire before trying to effect the repair." After describing the process of replacing a broken spoke, repairing a puncture, etc., about as well as it can be described in a book, it ends up with the following: "Customers of the Company will be instructed at the Company's offices, and in all the principal cycling centres agents have been, or will be, instructed, who, no donbt, will be prepared to show their respective customers how repairs *can* be effected." So, after all, a practical lesson is what is needed; and my advice to RETRENCHMENT, and all others who have the misfortune to possess a pneumatic machine, is to give it to a practical repairer. It will be cheaper in the end.—A. S. P.

**Pocket Medical Coil.**—A. E. J. (*Staleybridge*).—You evidently wish to have a small induction coil, small enough to go into a pocket and be worked by a silver chloride battery. The following dimensions will probably suit your requirements:—Core of No. 20 iron wire 3 in. in length, annealed soft and made into a bundle ⅜ in. in diameter. Cover the core with three layers of tough, thin paper, soaked in hot paraffin wax, and wind on two layers of silk-covered No. 24 copper wire; this is named the primary wire. Over this wrap two or three layers of the prepared paper above mentioned, then fill up the remainder of the 1¼ in. bobbin (to hold the coil) with No. 34 silk-covered wire, well soaked in hot paraffin wax. A magnetic contact-breaker must be fitted to one end of the coil, to be actuated by the magnetised core. The two wires from the battery must be connected to the two ends of the primary wire, one end of which will go to a binding screw and the other to the foot of the spring carrying the armature of the contact-breaker. A wire from the pillar of the contact stud to a binding screw connected to the battery will complete the circuit. A stinging shock will be given by the two ends of the secondary wire when two silver chloride cells are connected to the coil.—G. E. B.

**Kinetic Theory of Matter.**—ELECTRA.—I do not know certainly that there is such a theory in existence, consequently I cannot recommend "a good book on the modern kinetic theory of matter." What you are pleased to name a theory is merely a mode of expression applied to a fact. Kinetic energy is merely a term used by some persons to denominate energy of motion. That is to say, when matter is in motion, the velocity of its movement is distinguished by the term "kinetic energy." The word "kinetic" has a Greek origin, and is applied to "that part of mechanical science which treats of motion without reference to the forces producing it." I quote the following from Ganot's "Physics":—"The energy possessed by a body in consequence of its velocity is commonly distinguished as *energy of motion* or *kinetic energy;* it is measured by half the product of the moving mass into the square of its velocity."—G. E. B.

**Self-acting Fountain.**—T. N. D. (*No Address*).—You can purchase a fountain as described in No. 69 of WORK in London for about 37s., but name and address cannot appear in the columns of "Shop." If you send your address under cover to the Editor, I will give you the necessary particulars.—C. M. W.

**Compo Tubing.**—W. J. (*Rossendale*).—It is surprising that you should find any difficulty in obtaining this article at an ironmonger's. The fact must be that they do not wish to sell it. Compo tubing is a well-known article, and in daily use by all gasfitters in small sizes as a substitute for lead pipe. Have you tried getting it at a gasfitter's?—C. M. W.

**Iron Frame Piano.**—W. H. C. (*Tipton*) and WOULD-BE PIANO MAKER (*Cape Town, S. Africa*).—The instructions given in WORK on "How to Make a Piano" were written so as to make the proceeding as simple as possible, but the instructions there given require very little modification to accommodate them to the construction of an iron frame piano. Your best plan would be to purchase an iron frame. This you can obtain, already drilled and pinned, from W. Hughes, of Drury Lane, London, W.C. A 3 ft. frame would suit you—that is, that it is 3 ft. from the bottom to the top edge, which fits under the bottom edge of wrest plank. The back would only require six bracings, as the frame resists a large amount of the strain. The bent side need not be made of beech; spruce will do, as the frame merely rests on it and is bolted to it. It would be trichord to the covered strings. Your bridges on the sound-board will require to be 1½ in. in thickness, and as there are breaks in the frame, or bars to strengthen it, your bridge would be in three parts, one part supporting the covered strings and the remaining two supporting the steel. Your back would be 4 ft. 3 in. wide, and add a 9-in. wrest plank, and let the back extend two inches below the frame. When complete, with top and castors, your piano would stand 4 ft. 1 in. high. If you make the top bridge on the wrest plank, a couple of octaves, with a double row of bridge pins, it will make your treble brighter. You might write to W. Hughes, of Drury Lane, London, W.C.; he would probably supply you with all the materials you require, and give you the cost, as they could be packed in one case. Any further particulars you may require, write again.—T. E.

**Steps.**—E. H. (*Rawdon*).—Our subscriber wishes to know if the method he adopted to set out a string-board is correct: it has led to a successful result, so it must be free from serious error. His sketch is scarcely good enough to print, but as he asks for a correct way to arrive at the desired end, we will remind him of first principles. The treads of stairs ought to be level, and the risers vertical; that being so, the riser and tread are at right angles to each other on the exterior surface. If, therefore—neglecting for the moment the overhang of the tread, and regarding the thickness of the tread as added to the riser—E. H. takes a piece of board, having the ends accurately squared, and sets off the net width of tread, and on the adjacent edge the gross rise (that is, riser plus thickness of tread), by joining the points thus obtained he will have drawn a right-angled triangle, the third side of which is parallel to the edge of the string-board. A board such as this is usually prepared as a preliminary to staircase making, and is called a pitch-board. E. H.'s steps are too steep to be convenient: it is rare for the rising to exceed the forward movement, though it is sometimes needful when space is very restricted. Authorities give various data for determining the proportion between riser and tread. Some say tread plus twice the rise should equal 24 in.: thus, 10 in. forward would give 7 in. upward movement; others say these figures, multiplied together, should give an arbitrary number: about 70. This 70 would agree with the foregoing. By the first rule, 11 in. tread would require 6½ in. riser, which, if multiplied as the second rule, would give 71½. Other examples will show that these rules are, after all, mere generalisations, and that a comfortable staircase is only to be had by consulting the average length of step of the human species. Examples—tread 15, riser 4½, by first rule; tread 15, riser 4½, by second; tread 9, riser 7½, by first rule; tread 9, riser 7½, by second rule. These, of course, are extreme instances; in moderate cases the rules agree fairly. The rise should always

be equal in every stair between each floor.—B. A. B.

**Organ Accordion.**—G. T., J. B., and others.—This question must be treated in an article; the full description of how to make one of these is too long for "Shop." As some parts will be beyond the powers of an amateur to construct, we will find out if those parts are to be had at the musical fittings warehouse. Stands, reeds, and ivory for keys can be purchased, but some other parts offer difficulties not easily overcome.—B. A. B.

**Damp in Cylinder of Electric Machine.**—G. W. S. (*Biggleswade*).—You can only remove the dampness in the cylinder by warming it before a fire, turning the cylinder around as it gets warm. If the cylinder has wooden ends, drill a few fine holes in the wood to facilitate the escape of damp, and stop these with sealing-wax after the cylinder has been well warmed and you think all the moisture has evaporated.—G. E. B.

### III.—Questions Submitted to Readers.

**** *The attention and co-operation of readers of* Work *are invited for this section of "Shop."*

**Marionette Show.**—Marionette writes:—"Can any correspondent give me instructions as to how to construct a marionette show, size of the stage, how to fit up, etc., and whether I could make the figures? I want to show it next season. As I am an invalid, and have no means of earning my living, I might work one of the above. I saw a model theatre representing the Spanish Armada. Which would be the easier to make—the marionettes or the theatre?"

**Glass-Blowers.**—Drofsaba writes:—"Will anyone inform me of the address of an experimental glass-blower who deals in glass rods and tubing; also manufacturer of chemical and scientific glass ware, incandescent lamps, etc.? The address given of Mr. D. Williams, p. 668, Vol. III., in reply to Draughtsman, is of no use, as he has removed from that address."

**Embossing on Glass.**—Bonâ Fide will thank anyone who knows to kindly explain the method of embossing on glass with lead foil.

**Stain for Celluloid.**—Ebony writes:—"Will any kind reader give me a recipe for staining celluloid (imitation ivory) a black colour? I have some I want to stain, and have tried several dyes, but without any good results."

**A. S. L. Monogram.**—R. R. (*Greenock*) writes:—"I would be very much obliged to any clever reader who would be kind enough to give me a design for the initials A. S. L., to be inlaid as a centre-piece on lady's workbox. The top of box is 13 in. by 9 in., and has a Chippendale border round the edge."

**A. E. T. Monogram.**—Shamrock—an Emerald lad—will thank any reader for a suitable monogram with the letters A. E. T. to fit the shield drawn on p. 700 of Work, Vol. III.—[As Shamrock takes particular pains to emphasise the fact of his being "an Emerald lad," and we want to help the Irish cause, perhaps M. (*Bishop Auckland*) or some other tried correspondent will come to the rescue.—Ed.]

**Copies of Photographs.**—Rectilinear writes: "Will some reader of Work tell me how to get the best results in copying yellow and faded photographs, using ammonia, bromide of potassium, and pyro?"

**Monogram.**—T. W. T. (*London, N.*) writes:—"I should be obliged for a monogram for initials T. W. T. for painting on a Gladstone (brown) bag, ornamental preferred; also what kind of paint should I use? Would Aspinall's enamel or any other made-up paint do?"

**Leather Work.**—J. B. M. (*Blairgowrie*) writes:—"Will anyone tell me the best work on fancy and ornamental leather work? I have seen it made into picture-frames, brackets, etc. Also where is the best place to purchase the necessary tools, and their probable cost?"

### IV.—Questions Answered by Correspondents.

**Hand v. Treadle Fret-Saws.**—W. E. C. (*Wakefield*) writes, in reply to W. M. (*Brixton Hill*) (see Work, p. 654, No. 146):—"As an amateur with a long experience with treadle machines, both of my own make and invention, as well as others now in the market, I have no hesitation in strongly recommending him to go in for a good treadle machine with a vertical stroke and an even tension spring, which prevents the unpleasant upper resistance of the spring. All those machines on the principle of the Rogers, Windsors, Lester, and others with the oscillating arms and circular stroke, are really useless where good work is required. If W. M. is not in a great hurry to get a machine, I should strongly recommend him to wait until the Britannia Co. send out their new and improved machine, which has been already noted in one or two papers. He will then have a chance of purchasing a machine that has no equal."

**Market for Fretwork, Wall Designs, etc.**—F. Standage (*49, Fifth Avenue, Queen's Park, Harrow Road, London*) writes, in reply to Fretworker (see p. 733, No 150) and T. W. (*Accrington*) (see p. 732, No. 150), to say that he is open to consider novelties in these lines.

**Model Ship Building—Rig, etc.**—M. (*Bishop Auckland*) writes, in reply to Cutter (see p. 733, No. 150):—"I suppose you want a cutter rig. Make mainmast 22 in. above deck, ¾ in. diameter: topmast 11½ in., $\frac{7}{16}$ in. diameter; bowsprit, 12 in. long, projecting 5½ in. over stem; jibboom, 17 in. long, projecting 10 in. over bowsprit, and tapering from ½ in. to $\frac{5}{16}$ in. diameter; spanker boom, 18½ in. long, ½ in. diameter, tapering to $\frac{3}{16}$ in.; gaff, 13 in. long, ⅜ in. to $\frac{5}{16}$ in. diameter; topsail-yard, 5½ in. long, $\frac{5}{16}$ in. diameter. If you lay these down to scale, you will get the size of the sails, the mainsail, foresail, and jibsails being attached to the mast just under the crosstrees. You will require eight single-sheaved blocks and one double-sheaved block, eight dead-eyes for main shrouds, and six smaller dead-eyes for the stays. You will also require some cleats, fixed either at the foot of the mast or on the bulwarks, to fasten the halliards for working the sails."

**Naval Architecture.**—M. (*Bishop Auckland*) writes, in reply to Art T. (see p. 733, No. 150):—"Perhaps one of the following would suit you: 'Iron Ship Building,' by J. Grantham, 4s.; 'The Forms of Ships and Boats,' by W. Bland, 1s. 6d., published by Crosby Lockwood & Son, London."

**Engraving on Brass and Metal.**—M. (*Bishop Auckland*) writes, in reply to Nelson (see p. 732, No. 150):—"You will find instructions for this, and description of tools, on p. 595, Vol. I., of Work."

**Bamboo Flower Stands.**—M. (*Bishop Auckland*) writes, in reply to Melton Constable (see p. 733, No. 150):—"You can procure bamboo from Mr. F. Westbury, Great Dover Street, Boro'. For making joints, plug the end, glue, and fix with screw or wire nail."

**Fret Machine.**—M. T. C. (*Watford*) writes:—"If W. M. (*Brixton Hill*) (see p. 651, No. 145) will try the Dexter C. Fret machine, he will find it all that he can desire. I have had one in use for the last three years, and it is a first-rate machine."

**Cutter Yacht.**—Eddifra writes, in answer to Cutter (see p. 733, No. 150):—"I have a 24 in. model cutter yacht. The spars and sails were calculated as follows: Divide length of boat into twelve equal parts, and step the mast at the fifth mark from bow, at right angles from water-line. Let the mast rise above the deck just double as far as it stands from the bow. Let the bowsprit project beyond the bow the same distance the mast is stepped behind it. Let the mainboom be the same length as the mast rises above the deck, and let it slant upwards a little to clear water when the vessel heels. The length from the stern to the tip of the bowsprit will give you the height the topmast-head should be above deck. For the sails, halfway between stem and stern draw a line parallel to the mast half as long again as the length over all, or, in other words, three times as long as the distance between the line and stem and stern. From the end of this draw one line to the end of mainboom, and another to the bow. In the line to the boom take a point at the same distance from the top as the topmast projects beyond the mast; halfway between, where the line to the bow cuts the topmast and the deck, take a point in the lower mast: joining these you will get your mainsail, with gaff at its proper angle. The jib you get by joining the head of the lower mast with the end of the bowsprit; the foresail by drawing a line from the crosstrees to the bow. The line drawn to the bow from the perpendicular parallel to the mast gives you the position and angle of the topsail-yard, which, on the bow side, should be as long as the distance down the yard from the perpendicular to the mast, and on the stern side just as long as the part of the bowsprit which projects beyond the boat's bow. A line from where the yard crosses the topmast will give you the stay for the jib topsail. Perhaps this will be a puzzle to you, but if you will draw it full size, you will, I think, be able to work it out."

**Breeding Cage.**—F. H. (*Battersea*) writes, in answer to Gamma (see p. 702, No. 148):—"I would advise Gamma not to make a fancy breeding cage if he intends to keep birds in it. A fancy cage will give him endless trouble. A breeding cage should be made as plain as possible, avoiding all fretwork—in fact, as little wood as possible should be employed. If Gamma wishes to make a model of a Gothic building, let him do so by all means; but make a breeding cage for the comfort of the birds, and not for show. For making breeding cages, see Nos. 54 and 80 of Work."

### V.—Letters Received.

Questions have been received from the following correspondents, and answers only await space in Shop, upon which there is great pressure:—A. R. (*Scorrier*); J. B. (*Keighley*); W. K. (*Watford*); A. C. (*Falfield*); J. Y. (*Woolwich*); G. A. M. (*Partick*); F. J. (*Oldham*); W. Y. B. (*Deptford, S.E.*); F. H. R. (*York*); Reader (*Aberdeen*); A. T. (*Sheffield*); J. H. (*Walsall*); J. C. CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

"WORTH A GUINEA A BOX."

# BEECHAM'S PILLS.

LARGEST SALE IN THE WORLD.

*A WONDERFUL MEDICINE for all Bilious and Nervous Disorders,*

SUCH AS

**Sick Headache, Constipation, Weak Stomach, Impaired Digestion, Disordered Liver, and Female Ailments.**

Prepared only and Sold Wholesale by the Proprietor. THOMAS BEECHAM, ST. HELENS, LANCASHIRE.

Sold by all Druggists and Patent Medicine Dealers everywhere, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.
Full directions with each box.

## BEECHAM'S TOOTH PASTE

Will recommend itself: it is efficacious, economical, cleanses the teeth, perfumes the breath, removes tartar, and prevents decay. It is composed of the best-known ingredients for neutralising the acids of the mouth, preventing all deleterious deposits upon the teeth (which cause them to decay and become loose), and the CURE of spongy or unhealthy gums, and is a pleasant and reliable dentifrice.

BEECHAM'S TOOTH PASTE is put up in collapsible tubes, perfectly air-tight, and so adjustable that no waste need occur: the packages are pretty for the toilet table, and most convenient for the travelling-bag. They are sold everywhere for One Shilling each.

## PROFITABLE HOME WORK.

With BOOTH BROTHERS' **Registered Mitre-Cutting Machine**, any person, without previous instruction or practice, can make a Picture Frame. This Machine is now largely used in the Trade, nearly 6,000 having been sold. Write for Illustrated Circular to the Sole Makers—

BOOTH BROTHERS,
*TOOL MAKERS, DUBLIN.*
